University of London

The background of the entire image is a marbled paper pattern. It features a complex, organic design with swirling, cell-like shapes in various shades of blue, from deep navy to a lighter, almost turquoise. These blue shapes are separated by thin, irregular veins of a golden-yellow color. The overall effect is reminiscent of traditional marbling techniques used in bookbinding.

LIST OF MAPS IN VOLUME VII.

	PAGE
NEW SOUTH WALES	472
NEW ZEALAND	488
PALESTINE	712

Among the more important articles in this Volume are the following:

MANCHESTER.....	Sir SYDNEY CHAPMAN, K.C.B.	NEGROES.....	NORTHCOTE W. THOMAS.
MANICHEANS.....	Professor F. C. BURKITT, D.D.	NELSON.....	Sir J. K. LAUGHTON.
MARINES.....	Admiral Sir REGINALD TUPPER, K.C.B.	NERVOUS SYSTEM.....	Dr ALEXANDER BRUCE; Dr A. NINIAN BRUCE.
MARK; MATTHEW.....	Rev. Professor H. T. ANDREWS, D.D.	NEW GUINEA.....	Professor A. H. KEANE; W. E. ARMSTRONG.
MARLOWE; MARSTON..	A. H. BULLEN.	NEWMAN, JOHN HENRY	RICHARD HOIT HUTTON.
MARRIAGE.....	NORTHCOTE W. THOMAS; Sheriff J. M. IRVINE, K.C., LL.D.	NEW SOUTH WALES....	ARTHUR W. JOSE.
MARY, QUEEN OF SCOTS	JOSEPH ROBERTSON.	NEWSPAPERS.....	LORD RIDDELL.
MASORAH.....	HERBERT LOEWE.	NEWT.....	Professor J. ARTHUR THOMSON.
MASTER AND SERVANT..	Sheriff J. M. IRVINE, K.C., LL.D.	NEW ZEALAND.....	HON. W. PEMBER REEVES.
MATTER.....	Sir OLIVER LODGE.	NICKEL.....	Professor HENRY BRIGGS.
MAURICE.....	THOMAS HUGHES.	NIETZSCHE.....	Professor SETH PRINGLE PATTISON.
MEDAL.....	JAMES PATON.	NITROGEN.....	Dr LEONARD DOBBIN.
MEDICINE.....	Dr JOHN D. COMRIE.	NITRO-GLYCERINE.....	Col. Sir H. W. BARLOW, Bart.
MEDITERRANEAN.....	Sir JOHN MURRAY, K.C.B.	NORFOLK; NORWICH...	J. C. GROOME; G. A. STEPHEN.
MEMORY (Diseases of).	Sir JOHN MACPHERSON.	NOSE.....	Professor HAYCRAFT; Dr A. NINIAN BRUCE.
MENDELSSOHN.....	H. WHITEHEAD.	NOVELS.....	JOHN ORMSBY.
METALS; METALLURGY.	J. CAMPBELL SMITH.	NURSING.....	Miss E. S. HALDANE.
METHODISM.....	Rev. JOHN TELFORD.	OATH; NEUTRALITY....	Sheriff J. M. IRVINE, K.C., LL.D.
METRE.....	LASCELLES ABERCROMBIE.	OATS.....	Professor J. A. S. WATSON.
MICHELANGELO.....	CHARLES WHIBLEY.	OBSERVATORY.....	Sir FRANK DYSON.
MIGRATION.....	Professor J. ARTHUR THOMSON.	OBSTETRICS.....	Dr R. MILNE MURRAY; Dr R. W. JOHNSTONE.
MILL, JOHN STUART...	Professor SORLEY.	OGAM.....	Right Hon. Sir JOHN RHYS.
MILLAIS; MILLET.....	JOHN M. GRAY.	OPTICS.....	Dr ALFRED DANIELL.
MILTON.....	RICHARD GARNETT, LL.D.	ORCHARD.....	R. D. BLACKMORE.
MIMICRY.....	Professor EDWARD B. POULTON, F.R.S.	ORDERS, KNIGHTLY....	Sir JAMES BALFOUR PAUL, Lyon King.
MINES (Military).....	Col. Sir H. W. BARLOW, Bart.	ORDNANCE SURVEY.....	Colonel S. C. N. GRANT, C.B., late Director-General.
MINIATURE PAINTING..	H. B. WHEATLEY.	ORE-DEPOSITS.....	Professor HENRY BRIGGS.
MINING.....	Professor HENRY BRIGGS.	ORE-DRESSING.....	Professor S. J. TRUSCOTT.
MINT.....	Sir EDWARD RIGG; W. J. HOCKING.	ORIGEN.....	Rev. A. P. DAVIDSON.
MIRABÉAU; MUSSET...	THOMAS DAVIDSON.	OSSIAN.....	Professor D. MACKINNON.
MIRACLE.....	Rev. Professor H. T. ANDREWS, D.D.	OSTIA.....	Dr THOMAS ASHEY.
MISSISSIPPI-MISSOURI.	Professor J. P. LAMBERTON.	OTTER.....	Professor J. ARTHUR THOMSON.
MOABITES.....	Dr STANLEY A. COOK.	OVID.....	Dr J. P. STEELE.
MOLE; MOLLUSCA.....	Professor J. ARTHUR THOMSON.	OXYGEN; OZONE.....	Dr LEONARD DOBBIN.
MOLECULE.....	Sir OLIVER LODGE.	PACIFIC.....	Sir JOHN MURRAY.
MOLIERE.....	Professor SAINTSBURY.	PAINTING.....	P. G. HAMERTON.
MONEY.....	Professor J. S. NICHOLSON.	PALEOGRAPHY.....	Professor A. SOUTER.
MONGOLIA; MONGOLS..	Professor E. M. PARKER.	PALEONTOLOGY.....	Professor JAMES GEIKIE.
MONKEY.....	Dr FRANK BEDDARD.	PALATE; PELVIS.....	Professor DAVID HEPBURN.
MONOCOTYLEDONS.....	GEORGE WEST.	PALESTINE.....	Dr E. W. G. MASTERMAN.
MONTAIGNE; MORE....	Professor P. HUME BROWN, LL.D.	PANCHATANTRA.....	Prof. ARTHUR BERRIEDALE KEITH.
MONTESQUIEU.....	Professor HASTIE.	PAPER.....	CLAYTON BEADLE; Dr H. P. STEVENS.
MONTROSE, Marquis of.	F. HINDS GROOME.	PARASITIC ANIMALS...	Professor J. ARTHUR THOMSON.
MOON.....	Sir FRANK DYSON, Astronomer-Royal	PARDON; PARENT AND CHILD.....	Sheriff J. M. IRVINE, K.C., LL.D.
MOORS; NAVARRE.....	Rev. WENTWORTH WEBSTER.	PARIS.....	GEORGE BARCLAY; Sir THOMAS BARCLAY.
MORMONS.....	F. D. RICHARDS, Historiographer.	PARSONS, FATHER.....	T. G. LAW, LL.D.
MORRIS, WILLIAM.....	J. W. MACKAIL.	PASCAL.....	THOMAS DAVIDSON.
MORTGAGE.....	NORMAN MACDONALD.	PATENTS.....	Sir A. WOOD RENTON.
MOUNTAINS.....	Professor JAMES GEIKIE.	PAUL, ST.....	Dean FARRAR.
MOZART.....	Professor FRANKLIN PETERSON.	PEACE, &c.....	Sir THOMAS BARCLAY.
MUSCLE.....	Professor DAVID HEPBURN.	PEAR.....	R. D. BLACKMORE.
N, O, P.....	Dr HENRY BRADLEY.	PEAT.....	Professor W. A. BONE.
NAMES.....	Professor ALLEN MAWER.	PERKING.....	Professor LEGGE; Professor PARKER.
NAPOLEON.....	Lieut.-Colonel CLAYTON, R.A.	PELASGIANS.....	Professor F. B. JEVONS.
NAPOLEON III.....	F. F. ROGET.	PENDULUM.....	R. E. ANDERSON.
NATIONAL DEBT.....	Professor J. S. NICHOLSON; Dr M. T. RANKIN.		
NATURALISATION.....	Sheriff J. M. IRVINE, K.C., LL.D.		
NAVY.....	Captain GARBETT, R.N.; Admiral Sir REGINALD TUPPER, K.C.B.		

A great many of the articles named above are new; others written for earlier issues of this Encyclopædia have been so thoroughly revised by their authors as to be virtually new. In addition to these many other revisers have taken part, including Professor J. A. S. WATSON (Agriculture), Professor DAVID HEPBURN (Anatomy), Dr DRINKWATER (Chemistry), Dr R. CAMPBELL (Geology), Mr G. E. SHEPHERD (India), Mr W. A. FLEMING, Advocate, and Mr NORMAN MACDONALD, Advocate (Law), Dr J. D. COMRIE (Medicine), Admiral Sir REGINALD TUPPER (Navy), Dr ALFRED DANIELL (Physics), Professor A. BERRIEDALE KEITH (Sanskrit), Dr S. A. COOK and Mr HERBERT LOEWE (Semitic Subjects), Dr F. E. BEDDARD and Professor J. ARTHUR THOMSON (Zoology). Thanks are due to many town-clerks and others for information and corrections.

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Manchester lies on the east bank of the Irwell, which divides it from Salford. The two places may be regarded to-day as making a single town, though they are governed by independent corporations. The origin of Manchester can be traced back to Roman times, but there is still doubt as to the name with which it began. *Mancunium* is the usually accepted Latin name, but throughout the Middle Ages the place was invariably known as *Mamecestre*, which cannot be derived from *Mancunium*. It is not unlikely that the Latin was really *Manucium*, which occurs in the Itinerary of Antonine; and it has been suggested that the earliest form was *Mammium*, which could have been altered into either disputed form.

Despite its early beginnings, it was not until modern times that Manchester achieved distinction, but it is now one of the cities of the world, both because of the part played by it in the initiation of the present economic epoch, and because it presents unique features. It was in and around Manchester that the industrial revolution made its first noticeable marks and proceeded with greatest rapidity. Consequently problems connected with the industrial revolution were peculiarly associated with this great Lancashire town. The attitude to these of the new men naturally came to be designated as that of the Manchester School, in view of the fact that Manchester dominated the area of greatest disturbance, and that many of the new men who voiced the new ideas were connected with Manchester. The prominence in and about the town of the Radical movement of the first quarter of the 19th century is signified historically by the 'Peterloo Massacre,' which took place where a building now stands to commemorate the part played by Manchester men in another social movement, also connected with the industrial revolution, which followed some years later. The building is

the Free Trade Hall, and the movement was that initiated and engineered by the Anti-Corn Law League (led by Richard Cobden), the seat of which, naturally enough, was Manchester. From the point of view of social history, therefore, Manchester is of peculiar interest; and, as will be explained later, to the historic interest there has been added another, connected with the present relation of the town to the business activities of Lancashire.

It must not be supposed, however, that Manchester first came into business notice when the industrial face of the country was being transformed a hundred years ago. Mention of it as a town of economic importance will constantly be met with in works of standing in the 16th and particularly in the 17th century. Some connection with textiles no doubt dates back to the 13th century, but it was not until later that Manchester began to assume an outstanding position. Camden, who visited it in the reign of Elizabeth, describes it as 'surpassing neighbouring towns in elegance.' 'Here,' he says, 'is a woollen manufacture, church, market, and college. In the last age it was more famous for the manufacture of stuffs called Manchester cottons and the privilege of sanctuary, which the parliament under Henry VIII. removed to Chester.' In 1641 Lewes Roberts, in his *Treasure of Traffic*, writes, with reference to the cotton and linen manufactures, that the people of Manchester should be 'remembered, and worthily, and for their industry commended.' Again, in 1724, Stukeley describes it as 'the largest, most rich, populous, and busy village in England. Here,' he adds, 'are about 2400 families, and their trade, which is incredibly large, consists of fustians, tickings, girthwebbs, and tapes, which are dispensed all over the kingdom and to foreign parts. . . . On the same river for the space of three miles are sixty water-mills.' It was the coming of the cotton industry which gave Manchester rank among the chief towns of England. As Daniel Defoe observed in the course of his tour in 1727, 'the grand manu-

facture which has so much raised this town is that of cotton in all its varieties.' By 'cotton' he meant cotton proper, and not the coarse woollens which under the name of cottons had won for themselves a reputation generations before. For some years in and about Manchester the cotton and woollen industries flourished side by side; but the former, introduced probably in the second half of the 16th century, eventually pushed the latter over the Pennine Range, and in the period 1770-88, according to Radcliffe, the author of *The Origin of the New System of Manufacturing*, 'cotton was become the almost universal material for employment.' At the end of the 18th century Manchester was a pre-eminent manufacturing town, but its form then was very different from what it is to-day. In those times, where there are now streets of vast warehouses and offices, buildings stood, part residences and part business premises, in which Manchester merchants lived and stored their goods, and from which they put out their work to the numerous hand-loom weavers and small manufacturers in the vicinity. A faithful and picturesque account of Manchester life in these pre-factory days, and of the general features of the town, will be found in Mrs Linnaeus Banks's *The Manchester Man*. Around these merchants' premises factories soon sprang up, and Manchester became a mixed textile manufacturing (including spinning) and commercial centre, with numerous subsidiary industries such as machine-making.

The next epoch in the history of Manchester is signalled by its development as a marketing-centre. It is this characteristic, namely, that of serving as the trading nucleus of an extensive industrial district, which in the main renders Manchester a striking type of town organisation at the present day. Spinning and manufacturing, and even machine-making, were continuously pushed in bulk south and north and west, but they were not completely dissevered from Manchester. The necessary trading functions connected with the cotton industry were conducted on the Manchester Exchange, which has more than once been housed in a larger building. A large extension of the present building has been made. The Exchange, it may be incidentally remarked, is maintained out of the subscriptions of members, and is managed by a board of directors. When spinning separated to a large extent from weaving, the exercise of the marketing functions uniting them became of paramount importance, for the spinner and weaver had to keep in constant touch with one another for the purposes of sale and purchase of the material for cotton cloth; and a marketing-centre was also needed for the disposal of the cotton cloth. With regard to the cotton-wool, however, for the feeding of spindles, the market for this concentrated at Liverpool, its natural home, after the opening of railway communication between the two towns. Previously spinners bought, as a rule, from Manchester cotton-dealers, and up to 1789 the leading cotton mart had not been Liverpool but London. It is to be noted that a portion of the raw cotton market, but only a fraction, has been recovered for Manchester since its transformation into a port by the opening of the Manchester Ship-canal. It is the proximity of the manufacturing places in Lancashire to a marketing-centre with which they are united by a dense network of railways, offering frequent services, which accounts for the highly differentiated form of the Lancashire cotton industry when compared with the same industry on the Continent and in America, where the same crowding of the industrial centres around commercial centres is not to be found.

Manchester serves as a market not only for the home trade, but also for the foreign trade; and it

is from the foreign trade, which has assumed prodigious dimensions, that Manchester has received its cosmopolitan character. At first the foreign trade was carried on by travellers abroad representing Manchester firms, just as the home trade between merchants and retailers used to be conducted through the medium of 'riders out' with samples. But the method of using the English traveller to get in touch with foreign demand was soon found to be unsatisfactory. The travellers knew little of foreign conditions, and, however long their acquaintance with another country, they seldom learned to read its needs as a business man of the country could. Consequently the tendency soon appeared for the foreign houses to send their representatives to Manchester and establish offices there instead of awaiting the travellers from Manchester firms. In a sense the foreign business of every important country has permanently affixed one of its tentacles to Manchester, with the result that the latest demands of other countries can now be learned from visits to offices in Manchester streets instead of being gleaned piecemeal, imperfectly and slowly, from the correspondence of travelling representatives. The extent to which this transference of commercial points from abroad to the metropolis of the cotton industry has proceeded may be gathered from a walk through Manchester streets when attention is given to the names on the doorplates of the various offices. At first the invasion of the foreign business man excited not a little distrust, but to-day it is realised that through this invasion foreign trade has been assisted in attaining its present dimensions. With this remodelling of Manchester into an outstanding commercial centre there has been associated the development of credit facilities, since finance plays so large a part in modern commerce, and, indeed, in modern industry also. The leading banks of the country have important branches in the metropolis of the cotton industry, which do duty as centres for smaller branches in various cotton-towns; and there have appeared in addition (as should perhaps have been mentioned first) powerful local banks with their head-offices in Manchester, just as there has arisen for the same reason a local railway system, namely, the Lancashire and Yorkshire, which is managed from Manchester. Thus Manchester is to-day a metropolis somewhat in the same sense that London is a metropolis. London is the financial and business centre of the whole country. Similarly Manchester is the financial and business centre of the cotton industry and trade and all that is subsidiary to it. But the Lancashire district is not, therefore, self-contained and unlinked from the national metropolis, for the credit system of the country is substantially one, and it must be largely through the national metropolis that Lancashire business interests are brought into relation with those of other parts of the country. The development of the twin city of Manchester and Salford is to be read to some extent from the population figures below:

	Manchester.	Salford.	Total.
1801.....	75,300	14,500	89,800
1851.....	303,400	102,450	405,850
1871.....	351,200	124,800	476,000
1881.....	462,300	176,250	638,550
1901.....	544,000	220,950	764,950
1911.....	714,350	231,350	945,700
1921.....	730,307	234,045	964,352

This growth is partly to be explained by incorporation of new areas from time to time. An area of about 4300 acres was extended to 6000 acres in 1885, 13,000 in 1890, 20,000 in 1904, and 21,650 in 1909. Apart from London and Glasgow, Manchester and Salford together make up the largest town in Great Britain, in respect of population,

according to the census of 1921. Next to it stood Birmingham with 919,444, Liverpool with 802,940, and Sheffield with 490,639.

Facilities for transportation more than anything else govern the economic development of districts. Manchester has been fortunate in its proximity to a port, and it has been peculiarly fortunate also in having taken early steps to meet the needs of its trade by improving means of communication. In 1720 an act was obtained to make the Irwell navigable. In 1759-61 the Bridgewater Canal was constructed (by Brindley on the undertaking of the Duke of Bridgewater), which put Manchester in touch with the coalfields of Lancashire and, later, with the salt-mines of Cheshire, and made an outlet to the sea. Other canals which followed were the Ashton and Oldham, the Manchester, Bolton, and Bury, and the Rochdale. In 1830 Manchester had the first perfect railway in full operation between it and Liverpool, and at the present time no town in England is better served with railways. Moreover, in order to avoid transhipment of goods and to render Manchester an inland port, the gigantic work of making a ship-canal was carried out in 1887-94 at a cost of about £14,000,000, including the purchase of land and the Bridgewater Canal. The total amount charged to capital now stands at nearly £18,000,000. Through this canal Manchester has been made a port of no mean size in respect of tonnage cleared.

Though the name of Manchester calls up first in the mind the conception of a vast business system, it is not for its business alone that Manchester is of interest. It is of interest also on its administrative side, again on account of its past and of its present activities. Manchester received a charter from the last of the Grelleys in 1301, seventy years after the chartering of Salford by Randle de Blundeville. Prior to 1301, however, Manchester (or Mamecestre, to give it the name by which it was then known) had certain borough characteristics. Burgage tenements, a borough court, a weekly market, and a three days' fair (granted by Henry III. in 1227) were all in existence. The last was held until early in the 19th century on the spot now known as St Ann's Square. It was then twice removed, and finally abolished in 1876. Despite the charter of 1301, it was formally decided in 1359 that Manchester was no borough, but a market town, the reason being, no doubt, that a distinction was drawn between royal charters and those received from lords of the manor. Why Manchester was omitted, therefore, from the list of 246 corporations 'possessing and exercising municipal functions,' drawn up in 1833 by the Municipal Corporation Commissioners, is comprehensible. In 1791, however, some of the benefits of incorporation had been anticipated by the transference of the government of the town to police commissioners. Incorporation came in 1838. In connection with the agitation for it, Richard Cobden's pamphlet, *Incorporate Your Borough*, is worthy of note. In 1839 the first commission of the peace was created; in 1847 a bishopric followed; in 1853 the title of City was conferred, and in 1893 its chief officer received the title of Lord Mayor. In 1888 it became a county borough under the Act of that year. The Reform Bill of 1832 gave Manchester two members of parliament and Salford one. The Act of 1867 gave them three and two members respectively; and from 1885 Manchester had six, until they were increased to ten (1918), and Salford three members.

Of late years the corporation of Manchester has gone a long way in assuming control of its public services. Gas, water, electricity, and the tramway system have all been municipalised. To improve the water-supply, obtained in the main from Longdendale valley, reservoirs having been constructed

in 1848 and extended in 1884, connection was established with Thirlmere in 1894, the year in which the Manchester Ship-canal was completed after the final stages had been rendered possible by a loan to the directors from the corporation. On the educational side also a progressive policy has been pursued. The schools of the city under public control are numerous and attain a high standard of efficiency, and in addition a municipal college of technology has been established on a palatial scale. Such of the work in this college as is of university character is now organised as the Faculty of Technology of the University of Manchester.

Among the features of Manchester, apart from business, the university is one of the chief. It began as the Owens College on the basis of an endowment left by John Owens in 1851. In 1870 it acquired new buildings, and ten years later it received a royal charter as the Victoria University, with which the college of Liverpool and eventually that of Leeds were associated. In 1904, in consequence of the development of university teaching in the north, the federal university split into three, and the Victoria University became the independent Victoria University of Manchester. At this time among the changes made was the institution of a Faculty of Commerce. Shortly after its foundation the Owens College took a high rank, notably in science, and particularly, perhaps, in chemistry, and for many years now it has been admirably equipped all round, in the arts and other faculties as well as in science. In addition to the university there are also in Manchester a famous Grammar School and a well-known High School for Girls. The Grammar School dates back to 1515, in which year it was founded by Hugh Oldham, Bishop of Exeter. It has produced many eminent men, and at the present time is one of the largest public day-schools in the country. Almost as old as the Grammar School is the Blue Coat School, founded, together with a library, by Humphrey Chetham in 1653. In addition to the Chetham Library, containing some rare books and manuscripts, and the Free Reference Library, maintained by the corporation together with numerous branch libraries, there are two other libraries of note in Manchester, namely, the Christie Library and the John Rylands Library, which, in respect of the value of its possessions, is of world-wide repute. The John Rylands Library possesses the famous Althorp collection of books, and was presented to the town in 1892 in commemoration of John Rylands, a Manchester warehouseman and manufacturer, by his widow. On the cultural side Manchester has for long been to the fore among English cities, in this respect almost rivalling Edinburgh. Of the existing daily papers, the *Manchester Guardian*, founded early in the century, ranks with the best in the country. The Literary and Philosophical Society, which contains on its roll of members the distinguished names of Benjamin Franklin, Thomas de Quincey, John Dalton, Sir William Fairbairn, James Nasmyth, and Dr Joule, dates back to 1789. The Statistical Society was instituted in 1833, a year before the London one.

Manchester has in addition several first-class theatres, and maintains among its concerts the famous Halle Concerts. There are also several museums and art galleries. The chief museum is maintained by the university, but it receives a grant from the corporation, which also shares in its management. The chief art gallery is located at present in somewhat cramped premises in Mosley Street. The parks are also worthy of mention. Of public buildings the most striking are the Town Hall, which contains some remarkable paintings

on its walls by Ford Madox Brown, the Law-courts, and the University (all designed by Waterhouse), and the Cathedral. The Cathedral, formerly known as the College Church, was built in 1422, but between 1845 and 1868 it underwent complete restoration.

See Whittaker's *History of Manchester* (1771); Reilly's *History of Manchester* (1861); Baine's *History of Lancashire* (1870); Proctor's *Memorials of Manchester* (1880); Axon's *Annals of Manchester* (1886); Saintsbury's *Manchester* (1887); Tait's *Medieval Manchester and Beginning of Lancashire* (1904); Chapman's *Lancashire Cotton Industry* (1904); Bamford's *Early Days* (1848) and *Passages in the Life of a Radical* (somewhat earlier), both republished in 1893; Victoria County History (volumes on Lancashire); and Prentice's *Historical Sketches and Personal Recollections of Manchester* (1850).

Manchester, the largest city of New Hampshire, stands mostly on the east bank of the Merrimac River, 16 miles S. of Concord, 59 miles NNW. of Boston by rail. Its principal streets are wide and shaded with elms, and it has several public parks. The river here falls 54 feet, and affords water-power to numerous factories. The great industry of the place is its manufacture of cottons and woollens; but locomotives, fire-engines, sewing-machines, wagons, edged tools, boots and shoes, paper, &c. are also manufactured. Manchester is the seat of a Roman Catholic bishop, and has a Catholic orphanage and a convent, besides a state reform-school. Pop. (1870) 23,536; (1920) 78,384.

Manchester, EDWARD MONTAGU, second EARL OF, English general and statesman, was the son of the first earl, and was born in 1602. After leaving Cambridge—his college was Sidney Sussex—he accompanied Prince Charles to Spain, and afterwards was created Baron Montagu of Kimbolton. But siding with the popular party, and being an acknowledged leader of the Puritans in the Upper House, he was charged by the king (3d January 1642) with entertaining traitorous designs, along with the five independent members of the House of Commons. He succeeded his father as earl in the same year. On the outbreak of hostilities he of course fought for the parliament. He served under Essex at Edgehill, then held the associated (eastern) counties against Newcastle, took Lincoln (1644), and routed Prince Rupert at Marston Moor—that is to say, he nominally commanded; the real fighting was done by Cromwell and his Ironsides. He then marched to oppose the royalists in the south-west, and defeated them at Newbury (the second battle). But after this battle he again showed slackness in following up the victory, the same fault that had been noticed after Marston Moor. In consequence Cromwell accused him of military incompetency in the House of Commons, and the two had a downright quarrel. The Self-denying Ordinance deprived Manchester of his command, and this did not allay his bitterness against Cromwell. He opposed the trial of the king, and protested against the Commonwealth. Afterwards, having been active in promoting the Restoration, he was made Lord Chamberlain, a step designed to conciliate the Presbyterians. He died 5th May 1671.

His grandson, CHARLES MONTAGU, fourth EARL, supported William of Orange in Ireland, was sent as ambassador extraordinary to Venice (1696), Paris (1699), and Vienna (1707), and was made Duke of Manchester in 1719 for having favoured the Hanoverian succession. He died 20th January 1722.

Manchineel (*Hippomane Mancinella*), a tropical American tree of the natural order Euphorbiaceae, celebrated for the poisonous properties of its acrid milky juice. A drop of this burns like fire if it falls upon the skin, and the sore which it produces is very difficult to heal. The Indians use it for poisoning their arrows. The fruit is

not unlike a small apple; dried and pulverised it is diuretic; and still more so its seeds. The wood is well suited for cabinet-making.

Manchuria, the north-easternmost portion of the Chinese dominions, lies between the Yellow Sea and the Amur, and borders on Korea and Siberia. The area of Manchuria is said to be 360,000 sq. m.; total pop. 21,000,000. There are three provinces—Kirin in the centre, Feng-tien or Liao-tung in the south, and Hei-lung-chiang in the north. The eastern and most of the central parts are covered with the irregularly grouped ranges of the Long White Mountains, which in the White Mountain itself reach 8000 feet, whilst the northern province is crossed by the Chingan Mountains. The central parts of the country are watered by the Sungari, which rises in the crater-lake of the Long White Mountains, and after a course of 850 miles joins the Amur on the north border. The hills are rich in timber, pines predominating; in minerals, chiefly gold, silver, coal, and iron, little worked till lately; and in fur-bearing and other animals, as the sable, foxes, lynx, squirrel, tiger, bear, wolf, deer, &c. The Manchurian lark, a clever mimic, is exported in great numbers to China. The rivers swarm with salmon, and trout are plentiful. The climate is temperate in summer, especially whilst the rains last (May to September), but very severe in winter, the season of traffic, when the streams and extensive marshy tracts are frost-bound; the thermometer frequently falls as low as -25° F. in the northern province in the depth of winter. The soil is extremely fertile, and produces in abundance millet (with vegetables the chief food of the people), beans, wheat, rice, maize, hemp, vegetables, and ginseng. Cultivation of the soy (or soya) bean has developed prodigiously. Wild silk is produced. Manufactures for the most part are primitive, but there has been a very vigorous growth of factory enterprise under Russian, Japanese, and Chinese management. A large amount of trade is carried on at the towns in the interior, and especially at the treaty-port of New-chwang (q.v.). Beans, bean cakes and oil, silk, ginseng, skins and furs, &c., are exported, and cottons, woollens, metals, sugar, silk, paper, medicines, &c., imported. There is a railway, connecting with those of Chih-li, Dairen, and Korea, through southern Manchuria to Mukden and Kharbin, where it joins the Russian direct line ('Chinese Eastern') to Vladivostok, which crosses Manchuria from north-west to south-east. Floods have often caused severe famines. The population includes but few Manchus, and most of these dress and speak like Chinese. Yet they are the aristocracy of the country, furnishing its magistrates and soldiers, its police, and its hunters, though many cultivate their own land. From the time when the Manchus conquered China (1644) and founded the late imperial dynasty Manchuria was the favourite recruiting-ground for the Chinese army. The rest of the population consists almost entirely of Chinese immigrants, enterprising, industrious, and prosperous, and still pouring in. The principal towns are Mukden (q.v.), the capital; Kharbin (q.v.); Kirin (q.v.); Kwangcheng-tzu; Liao-yang; Tsitsihar; Ying-tzu, commonly called New-chwang, the chief port; Antung, also a great port. All Manchurian towns are indescribably filthy, worse than English towns in the 15th century, and most of them are walled. The religions current are those found in China (q.v.), though the original creed of the Manchus was Shamanism. Early in the 11th century B.C. there existed a native kingdom in the southern of the three provinces, and this was succeeded by other states, until in the beginning of the 17th century Nurhachu, a Manchu chief, founded a powerful

sovereignty; in 1644 his grandson ascended the throne of China, and thus founded the dynasty that reigned till 1911. The conquerors imposed upon the conquered the custom of wearing the pigtail. The first step in the Russian occupation was the concession by China allowing the deviation of the Siberian railway through Manchuria; then the events connected with the russification of Port Arthur (q.v.) and Ta-lien-wan. Finally it was arranged that the Siberian railway should be connected with Kirin and Mukden, with Peking on the one hand and Port Arthur on the other. Since the Russo-Japanese war of 1904-5 (see JAPAN) Japan holds a lease of the Liao-tung peninsula, and has railway and other trade privileges in southern Manchuria (the principal theatre of war). The Russians and the Japanese control the railways. In the Chinese civil wars General Chang-tso-lin, governor of Manchuria, played a leading part as the rival of General Wu-pei-fu. The Manchu language is of the Ural-Altaic family. The Manchu alphabet is of Syriac descent. See ALPHABET. French Catholics (since 1838) and Presbyterians (since 1861) have missions. See books by Hosie (1901), Whigham (1904), Weale (1904), Kemp (1912), Christie (1914), Sowerby (1923).

Mancini. See MAZARIN.

Manco Capac, mythical ancestor of the Incas.

Mancumium. See MANCHESTER.

Mandæans, a small sect found in South Babylonia and Khuzistân. The members are a fine race, chiefly gold and silver smiths and boat-builders; and their sacred books are written in a very archaic Aramaic dialect and script which date back before the 7th-8th centuries A.D. The religious beliefs, which are of remarkably diverse origin, are opposed to Judaism, Christianity, and the dualism of Manichæism (see MANICHÆUS), and have much in common with Gnosticism (q.v.). From ancient Babylonia are derived the names of certain deities, astral elements, the fight with darkness, Hibil's descent into the underworld, the sanctity of water, and the elaborate water-ritual. The Great Fruit (*Pira*) and the Great Vessel (*Mânâ Rabba*) stand at the head of the religious system. Then comes the First or Great Life, the King of Life, the source of all development and of the Great Jordan which encircles the celestial realm. Next follow the Second Life and the *Mandâ d Hayyâ* (Knowledge of Life, i.e. salvation), from whom the sect derives its name. He is source of life, mediator, and saviour. His three sons, messengers of the true religion, are Hibil (Abel), Sithil (Seth), and Enoch (Gen. iv. 26, fused with the Son of Man in Dan. vii. 13, and, like the latter, dwelling in a cloud). The Third Life is father of the '*Uthrê*' ('riches,' Mammons?), and his son Ptahil created the bodies of men, although the spirit comes from *Mânâ Rabba*. In another version this demiurge is Gabriel. The *Ruha* ('spirit') with her son '*Ur*' ('light')—both derived from Gen. i. 2 seq.—produced the planets, signs of the zodiac, &c., including Ishtar (Venus, or the Holy Spirit), Bel (Jupiter), Nebo (Mercury), Adonay (the founder of Judaism), and other sources of false religion and evil. The false prophets extend from Abraham to Mohammed. The true prophet was John the Baptist, Jesus being a false prophet (also identified with Mercury) whom Enosh exposed. The Mandæan reverence for John and the prominence of rites of baptism (*maṣbutḥa*)—Christian baptism being condemned—account for the misleading name of St John's Christians given to the sect (17th century onwards), and for the older title of Sabians (in the Koran), whence the modern name of Subbis. The native title, Naṣoræans, suggests the old Jewish-Christian Nazoræans; but

although there are resemblances to Ophites and other old sects, the name probably means 'observers,' i.e. men distinguished for their knowledge. Prayers are recited thrice during the day and twice at night. Emphasis is laid upon ritual rectitude and truth, and ritual purity; and there are some special food-laws. In course of time Christian, Jewish, Persian, and other influences continued to modify the religion (e.g. observance of the Sabbath, resurrection), even as they explain the heterogeneous elements already present in the sacred books. The light thrown by the Mandæan writings upon early beliefs in Babylonia prior to the age of Islam is of great value; but the analysis of the different elements, as will be seen from the above, is a very difficult task, upon which the chief work has been done by Brandt (see *Encyclopædia of Religion and Ethics*) and Lidzbarski (edition of texts); on the book of John see Mead, *The Quest*, vol. xv.

Mandalay, the chief town of Upper Burma, stands 2 miles from the left bank of the Irawadi, a little N. of Amarapura (q.v.), the former capital, and 410 miles by rail (1888) N. of Rangoon. Founded in 1860, it was the capital of independent Burma until its capture by the British in the end of 1885, and after the treaty (1886) by which the king lost his throne it became the capital of Upper Burma. The city forms a square, each side a mile long, and is surrounded by a wide moat, a crenelated brick wall 26 feet high, and an inner earthen parapet. In the centre of the city stand the royal palaces, constructed principally of teak-wood, and enclosed by three stone walls and a teak-wood stockade. There is little of real interest or beauty in them beyond some rich wood-carving. The most famous building in Mandalay is, however, the Arakan Pagoda; it contains a brazen image of the Buddha, 12 feet high, an object of veneration to thousands of pilgrims. Outside these enclosures was, until the British conquest, a crowded, dirty native town, now cleared away to make room for a British cantonment. The present native quarters lie outside the fortified city. Beyond them, again, on the slopes of the hills that border the valley of the Irawadi, are numerous fine monasteries. Pop. (1921) 148,917. Silk-weaving is the most important of the industries; the others are gold and silver work, ivory and wood carving, bell and gong casting, and knife and sword making. A disastrous fire in 1892 destroyed most of the town and facilitated the great improvements made since the British occupation. It has now fine well-lighted streets.

Mandamus is a writ, not of right but of prerogative, which issues from the Court of King's Bench, commanding some public body, or inferior court, or justices of the peace, to do something which it is their legal duty to do. In the United States the power to issue writs of mandamus is vested in the Supreme Court, and is also allowed to the circuit courts, subject to considerable restrictions.

Mandarin, a general term applied to Chinese officers of every grade by foreigners, derived from the Portuguese *mandar*, 'to command.' For the Chinese governmental authorities, their rank and distinctive buttons, see CHINA.

Mandeville, BERNARD, an English satirical writer, though born of Dutch parents at Dordrecht in Holland in 1670. He graduated in medicine at Leyden, after six years of study, in 1691, and immediately afterwards settled in London to practise his profession; he died in that city in 1733. He is known as the author of a short work in doggerel verse entitled *The Fable of the Bees*, which, as finally published in 1723, included the fable itself, called *The Grumbling Hive*, first printed in 1705, *Remarks on the Fable*, and *Inquiry into the Origin of Moral Virtue*, both added to the 1714 edition,

and *An Essay on Charity Schools and Search into the Origin of Society*, added in 1723. This book (ed. F. B. Kaye, 1925) was levelled against the ethical theories of Shaftesbury, who set up as the standard of virtue the ultra-refined tastes of an idealistic aesthete. Mandeville, writing in a vein of extremely coarse and brutal paradox, cynical in its frankness, though frequently of striking acuteness, affirms that 'private vices are public benefits,' and that every species of virtue is at bottom some form of gross selfishness, more or less modified. Thus he over-emphasises the baser elements in human nature, as Shaftesbury does the 'dignified.' The book was condemned by the grand jury of Middlesex as being immoral and pernicious in its teaching. Besides that, it was attacked by Law (q.v.) the nonjuror, by Berkeley, by Brown, Warburton, Hutcheson, and others. Mandeville in his defence states that he wrote in irony for the diversion of people of discernment and knowledge, and his words were not to be taken in literal earnest, as if meant for general readers. Nevertheless, his other works, such as *The Virgin Unmasked*, *Free Thoughts on Religion*, &c., detract greatly from the sincerity of this plea. It is worth while observing that his realistic habits of thought bring him in some respects curiously into touch with the exponents of modern scientific methods of inquiry.

See Sir Leslie Stephen, *Essays on Freethinking* (1873), and *English Thought in the 18th Century* (1876); Sakmann's *Bernard Mandeville* (1902).

Mandeville, JEHAN DE, the name assumed by the compiler of a famous book of travels, written in French, and published between 1357 and 1371. Versions in Italian, Spanish, Dutch, Walloon, German, Bohemian, Danish, and Irish are found, and the number of MSS. amounts to at least 300. Many have maintained the priority of the Latin text, which exists in as many as five independent versions, but it seems much more probable that the French was the earlier. The earliest edition of the French text was printed at Lyons in 1480. Indeed, it is most probable that the book was written under a feigned name by the physician Jehan de Bourgoigne, otherwise Jehan à la Barbe, who is stated in an early Latin edition to have met Mandeville first at Cairo, and again at Liège, and to have persuaded and helped him to write his travels. There can be little doubt that this statement of Bourgoigne's was merely an ingenious blind, and that he alone was the author of the book. But a statement has been discovered that Bourgoigne revealed on his death-bed his real name of Mandeville to Jean d'Outremeuse, explaining that he had had to flee from his native England for a homicide. We are told further that this physician, who died in 1372, had practised his profession at Liège since 1343. And it is apparently quite certain that in the 16th and 17th centuries a tomb was shown at Liège, with a Latin inscription stating that Mandeville died there in November 1372. An English version was made from a defective French manuscript at least as early as the beginning of the 15th century, and two extant independent revisions of this followed within a quarter of a century. The original defective form was printed by Pynson and Wynkyn de Worde (1499); the editions of 1725 and the well-known reprints by Halliwell (1839 and 1866) represent one of these later revisions; that first printed for the Roxburghe Club in 1889 is an admirable edition of the other. But the glaring errors of translation render it impossible that either of these forms of the English version can be from the hand which wrote the original work, in spite of the statement in the preface, which has been too easily believed, that it was made by Mandeville himself. None the less it remains an admirable

monument of English, but the name of Sir John Mandeville should now disappear from histories of literature as the 'father of English prose.'

In the preface the French compiler describes himself as a knight born at St Albans, who left his native country in 1322, travelled by way of Turkey, Armenia, Tartary, Persia, Syria, Arabia, Egypt, Libya, Ethiopia, Amazonia, and India, often visited Jerusalem, and who wrote in Romance as better understood than Latin. In the course of the book we are told further that he had served the sultan of Egypt against the Bedouins, and the emperor of China against the king of Manzi; that he had seen the glory of Prester John and drunk of the Fountain of Youth at Palombe (Quilon on the Malabar coast), and returned home unwillingly owing to arthritic gout in 1357.

By far the greater part of the book has now been proved to be borrowed, with interpolations, usually extravagant, from the narrative of Friar Odoric (written about 1330); from Hayton, an Armenian who became a Premonstratensian monk, and dictated at Poitiers in 1307 a book about the East in the French tongue; from the work of the Franciscan Carpini; from the well-known *Epistle of Prester John*, widely known in the 13th century; from Albert of Aix, Brunetto Latini, Peter Comestor, Jacques de Vitry, Vincent de Beauvais (*Speculum Historiale* and *Speculum Naturale*); from the 12th-century Latin itineraries of Palestine, and from the work of the German knight William of Boldensele, written in 1336. A small portion of the book may still represent actual travels and personal knowledge, especially in the part relating to the Holy Land; but this does not re-establish the honesty of the writer, who claims himself to have travelled in the remotest regions described, and to have seen with his own eyes the wonders enumerated, while he never mentions Odoric, from whom he conveyed by far the greater part of his book. Among these wonders we find stories of fabulous monsters, such as anthropophagi, and men whose heads grew beneath their shoulders, the phoenix, the vegetable lamb, the weeping crocodile, the garden of transmigrated souls at Cansay (Hang-choo-foo), and the Valley Perilous. Of the Terrestrial Paradise, however, the writer is candid enough to say that he had not been there.

See Yule and Nicholson in the *Encyclopædia Britannica*, Dr Albert Bovenschen, *Quellen für die Reisebeschreibung des Johann von Mandeville* (Berlin, 1888); the Introduction by G. F. Warner to his edition for the Roxburghe Club (1889), in which the views of Dr Vogels and Dr Carl Schönborn are also discussed; Alice Greenwood in the *Cambridge English Literature*, vol. ii.; and the edition by P. Hamelius (E. E. T. S. 1919-23).

Mandible, a name applied to various jaw-organs—e.g. the third pair of appendages in Crustaceans, the first pair of true appendages in Insects, the lower jaw in Vertebrates.

Mandingoes are a Bantu people of Africa, mainly in Senegambia (q.v.). See AFRICA.

Mandioca. See MANIOC, TAPIOCA.

Mandogarh, or MANDU, a ruined city of India, formerly capital of the Mohammedan kingdom of Malwa, stands 15 miles N. of the Nerbudda, in Dhar State (Central India). The ruins stretch for 8 miles along the crest of the Vindhya Mountains, and have a circumference of 37 miles. A deep, narrow valley separates them from the adjoining tableland. The least injured of the ruined buildings is the great mosque, which is reached by a handsome flight of stairs; it is said to be 'the finest and largest specimen of Afghan architecture extant in India.' There are also a massive royal palace and the white marble mausoleum of the king who raised the city to the acme of

its splendour (early 15th century). According to Malcolm, Mandogarh was founded 313 A.D.

Mandola, a musical instrument shaped like the eight-stringed Neapolitan mandoline, but larger and tuned an octave lower. The name is given in Venezuela to a small guitar whose apparently highest string gives a low note, thus ending a chord with a deep sound with strange effect.

Mandoline, a musical instrument of the lute family. The body is formed of a number of narrow pieces of different kinds of wood, bent into shape, and glued together. On the open portion of the body is fixed the sounding-board, with a finger-board and neck like a guitar. The Neapolitan mandoline, which is the most perfect, has four double strings, tuned (beginning with the lowest) G, D, A, E. The Milanese mandoline has six single strings, tuned G, D, A, E, B, C. The sound is produced by a plectrum in the right hand, the left hand fingering. In mandoline and guitar bands the mandolines play the first violin part, the mandola and lute, with guitars added, playing the accompaniments.

Mandrake (*Mandragora*), a solanaceous genus closely allied to *Belladonna* (q.v.). *M. vernalis* and *M. autumnalis* are both natives of the Mediterranean region and the East, and especially abound in Greece. The whole plant has a very fetid narcotic smell;

Mandrake.

and all parts have poisonous properties like those of belladonna, but more narcotic, for which reason a dose of the root was formerly sometimes given to patients about to endure surgical operations. The ancients were well acquainted with the narcotic and stupefying properties of mandrake, and it was a common saying of a sleepy or indolent man that he *had eaten mandrake*. The large taproot grows somewhat irregularly, and often seems divided into two, through the development of a branch which attains more or less equal size. Hence arises a rude resemblance to a human figure; and this is easily exaggerated by a little judicious pruning or carving, and by trimming the covering of fine hair-like roots. Hence Pythagoras speaks of the mandrake as *anthropomorphic*. To such mannikin-figures many magical virtues were ascribed: by the ancient Germans they were supposed to bring luck to their possessors, who accordingly dressed and tended them like dolls, yet kept them reverentially enshrined in caskets, and thus obtained their services for the healing of obstinate diseases of man and beast, for the divination of the future, or the ensuring of supplies of money. From the most ancient times aphrodisiac virtues have been ascribed to mandrake, which was therefore supposed to cure barrenness (see Gen. xxx. 14-16); such repute is hardly borne out by the actual properties of the root (which would, however, relax the womb), but probably more commonly depended on its magical associations as a phallic figure. The extremely

narcotic and poisonous properties of the plant could not but invest these figures with a more grim significance, of which the mediæval imagination made the most. So large, deep, and well fixed a root needs some labour to dig out, and if torn up by main force breaks with more or less noise, hence the ancient legend that the mandrake shrieks when torn out of the ground. The subsequent possibilities of accident (not to speak of misuse) can easily be imagined, not only from the sweet and attractive berries, but the leaves, root, or even juice. On the base of caution there arose a whole fantastic ritual: the plant could only be safely dug up at midnight, and when loosened by careful digging should be dragged out of the ground by a black dog, which served as a substitute for the herbalist. Mrs Campbell-Præd's *Insane Root* (1902) works in the fables.

Mandrill. See BABOON.

Manduria, a town of Southern Italy, 22 miles E. by S. of Taranto, near the ancient town of Manduria, of which some important relics are still extant; pop. 15,500. In 1790 it exchanged its name of Casalnuovo for Manduria.

Mandvi, the chief seaport of the principality of Cutch, in India, on the north shore of the Gulf of Cutch, 36 miles SW. of Bhuj, the capital. It has a good roadstead and a breakwater, but the harbour is choked with sand. The pilots are in request all through the state. Pop. 23,000.

Manes. See ANCESTORS (WORSHIP OF); LARES; and for Manes or Mani, see MANICHÆUS.

Manet, ÉDOUARD, French painter, was born in Paris, 23d January 1832, eldest son of a judge, from whom he inherited a considerable fortune, and was educated at the Collège Rollin. Intended for a barrister and elegant man of the world, he was sent on a voyage to Rio to distract his thoughts from art. Nevertheless he studied from 1850 to 1856 with Thomas Couture. Afterwards he travelled in Europe. At length he found in Velázquez and Hals the answer to his questionings after a just illumination and a true portrayal of nature. He first exhibited at the Salon in 1861, but on the classical tradition obtaining the upper hand he was excluded in 1863. With Monet, Renoir, and Whistler he showed his work in the *Salon des Refusés*, and from this meeting arose the solidarity of the Impressionist Movement (see IMPRESSIONISM). In 1873 he exhibited 'Le Bon Bock,' which showed his heirship to Velázquez and Hals as well as Courbet. 'A Bar at the Folies-Bergère' (1882) is a sparkling picture, more truly impressionistic, in which the almost infinite detail in the accessories is subordinated to the general composition. He died 30th April 1883. His dictum, since become famous, 'The principal person in a picture is the light,' sums up his aims.

Manetho, a celebrated Egyptian historian, native of Sebennytyus, a priest who flourished in the 3d century B.C. See EGYPT.

Manfred, regent and king of Sicily, was a natural son (afterwards legitimised) of the Emperor Frederick II. by Bianca, the daughter of Count Lancia, and was born in 1231. On his father's death in 1250 he received the principality of Tarentum, and in the absence of his half-brother, Conrad IV., acted as regent in Italy. He bravely defended Conrad's interests against the aggression of Pope Innocent IV., and after his death was acknowledged as regent of Apulia, in name of his nephew, Conradin (q.v.). The pope, however, renewed his pretensions to Apulia, and compelled Manfred to flee for shelter to the Saracens, by whose aid he defeated the papal troops, and became, in 1257, master of the whole kingdom

of Naples and Sicily. On the rumour of Conradin's death he was crowned king at Palermo, 11th August 1258, and immediately afterwards was excommunicated by Pope Alexander IV. along with his adherents; but Manfred invaded the papal dominions, and made himself master of the whole of Tuscany. His power now seemed secure, and his government was at once mild and vigorous. But this tranquillity was not of long duration. Pope Urban IV. renewed the excommunication against him and his friends, and bestowed his dominions as a papal fief on Charles of Anjou, the brother of Louis IX. of France. Manfred, though at first successful in the war which ensued, was at last treacherously defeated, and slain in a bloody battle at Benevento, 26th February 1266. His body was interred as that of an excommunicated person. His widow and children were barbarously treated by the French; the widow and three sons died in prison; the daughter was confined for twenty-two years. His history has been made the subject of drama and opera. See books by Cesare (1837), Schirmacher (1871), Karst (1897), and Hampe (1905).

Manfredonia, a walled seaport of Italy, on the Gulf of Manfredonia, a bay of the Adriatic, 23 miles by rail N.E. of Foggia. Founded by Manfred in 1261 from the ruins of ancient Sipontum, it has an old castle and a cathedral. Pop. 15,600.

Mangabey, a name applied to monkeys of the West African genus *Cercopithecus*, especially *C. fuliginosus*, the sooty mangabey. The mangabeys are long-tailed monkeys with white upper eyelids, lively and gentle in disposition.

Mangalore, a seaport and military station, chief town of South Kanara district, in Madras. A clean, picturesque town, embosomed in coconut groves, it ships much coffee (from Coorg and Mysore) in small Arabian and Indian vessels. Pop. 54,000, including a large body of Roman Catholics, who have a bishop and a college. The Basel Lutheran missionaries teach their people weaving, printing, bookbinding, and tile-making. From Mangalore the Madras Railway runs with a southerly bend across India. The town, which was three times sacked by the Portuguese in the 16th century, was taken by Hyder Ali in 1763. In 1784 its English garrison yielded to Tippoo Sultan after a nine months' siege. It became British in 1799, and was burned by the Coorg rebels in 1837.

Mangan, JAMES CLARENCE, a gifted Irish poet, was born in 1803, and employed for many years in the drudgery of copying in an attorney's office. His whole life was a tragedy of hapless love, poverty, and intemperance, until he died at Meath Hospital, Dublin, 20th June 1849. There is fine quality in his original verse, as well as in his translations from the German, but more especially from the old Irish, as in the impassioned ballad of *Dark Rosaleen*.

Miss Guiney, in her selections and study (1897), affirmed Poe's indebtedness to Mangan's recurrent refrains; the standard life is that of D. J. O'Donoghue (1898), who edited the *Poems* (1903) and the *Prose Writings* (1904).

Manganese (sym. Mn; at. numb. 25; at. wt. 55) is one of the iron group of heavy metals. It is darker than wrought iron, is capable of a high degree of polish, and is so hard as to scratch glass and steel. It is only feebly attracted by the magnet, and oxidises readily on exposure to the air. The metal occurs in nature in small quantity along with iron in meteoric stones, but may be obtained in large amount by the reduction of its oxides or carbonate by charcoal at an extreme heat.

With oxygen it forms six compounds: manganous oxide, MnO ; manganic oxide, Mn_2O_3 ; manganoso-manganic oxide, Mn_3O_4 ; manganese dioxide,

MnO_2 ; manganic anhydride, Mn_2O_3 ; and permanganic anhydride, Mn_2O_7 . Like iron it forms proto-salts, $MnCl_2$, and persalts, Mn_2Cl_6 . It also forms salts derived from an acid, H_2MnO_4 , such as potassium manganate, K_2MnO_4 , and from an acid, $HMnO_4$, as potassium permanganate, $KMnO_4$. The *binoxide*, MnO_2 , is the chief form in which manganese is found in nature, and is the general source of the other compounds. It is a soft, black, amorphous mineral, known to mineralogists as pyrolusite, and in commerce as black manganese or manganese simply. When heated alone or with sulphuric acid it gives off oxygen, and when heated with hydrochloric acid evolves chlorine. It is largely used in the manufacture of glass, to which it imparts a purple colour. It is also supposed to colour the amethyst.

Manganous oxide, MnO , is an olive-green powder. Its salts are colourless, or of a pale rose colour. The sulphate, $MnSO_4$, in pink crystals, is largely used by the calico-printer for the production of black and brown colours, by decomposing it with bleaching powder or an alkali.

Manganic oxide, Mn_2O_3 , in octahedral crystals, forms the mineral braunite, and in the hydrated form, $Mn_2O_3 \cdot H_2O$, the orthorhombic mineral hausmannite.

Red oxide of manganese, Mn_3O_4 , is formed when any of the other oxides are heated in the air. It is found in nature as the mineral hausmannite.

Manganic anhydride, Mn_2O_3 , is not known in the free state. It forms an acid and salts. Manganate of potassium, K_2MnO_4 , is in green crystals, and when its solution stands exposed to air the 'chameleon mineral' rapidly becomes blue, violet, purple, and finally red, by the gradual conversion of the manganate into permanganate.

Permanganic anhydride, Mn_2O_7 , is only known in solution or in a state of combination. Its solution is of a splendid red colour, but appears of a dark violet tint when seen by transmitted light. Permanganate of potash, $KMnO_4$, which crystallises in reddish-purple prisms, is largely employed in analytical chemistry. Very similar is permanganate of sodium, which is understood to be the basis of Condy's Disinfectant Fluid.

Manganese is a constituent of many mineral waters, and various preparations of it are employed in medicine; the binoxide has been used as a substitute for bismuth in dyspepsia. Alloys with copper and some zinc are used under the name of manganese bronze. The 'black oxides' (manganite, pyrolusite, psilomelane), long familiar in making chlorine and bleaching-powder and in decolorising glass, are now used in large quantities in iron-works (see IRON AND STEEL). They are mined chiefly in Brazil, in the Caucasus, and in India, which began to exploit its supplies only at the end of the 19th century. Rhodochrosite or manganese spar, the carbonate, is found, in beautiful rose-red crystals, in Rheinland, Transylvania, the Pyrenees, and Colorado. As it contains no dioxide it is of no use for the other named purposes, but only in iron-manufactures. Manganese occurs in many of the United States and in Australia.

Mange, a contagious disease which occurs in most animals, is, like scab in sheep, and itch in the human subject, due to the presence of minute mites or *acari*. Some of these burrow in the skin, others move about upon the skin, and cause much irritation, heat, and itching, and the eruption of minute pimples, with dryness, scurfiness, baldness, and bleaching of the skin. Mange in horses has been since 1911 scheduled under the Diseases of Animals Acts, and is a notifiable disease. The treatment consists in destroying the *acari*, and ensuring the cleanliness of the skin. Most of the better-known sheep-dips are equally efficacious in the treatment of mange, and if animals cannot be dipped,

they can be washed or sprayed. Animals with heavy coats are more easily treated after being clipped. Where the general health is indifferent, as in chronic cases, the patient should be liberally fed, kept clean and comfortable, have an occasional alterative dose of any simple saline medicine, such as nitre or common salt, and a course of such tonics as iron or arsenic. Cleanliness and occasional washing and brushing maintain the skin in a healthy state, and thus prevent its becoming a suitable nidus for the *acari*.

Mangel-wurzel. See MANGOLD-WURZEL.

Mangkassars. See CELEBES.

Mangnall, RICHMAL, of Irish extraction, but born probably in Manchester, 7th March 1769, was the head-mistress of a ladies' school at Crofton Hall, near Wakefield, and died there 1st May 1820. Few particulars of her personal history have been preserved; she survives only in her redoubtable *Questions*, the pride and terror of several generations of school-girls. She was an amiable and excellent woman, but as a writer she has been well called 'the very high-priestess of the great god Cram.' Of the popularity of her schoolroom encyclopædia, compiled entirely by herself, there can, however, be no doubt: an impression, printed in 1857 in America, was taken from the 84th London edition. It has been reprinted in England (ed. by Wright and Hodder) as recently as 1892.

Mango (*Mangifera indica*, natural order Anacardiaceæ), one of the most esteemed fruits of India. The tree grows from 40 to 50 feet high, with spreading top and numerous branches, at the extremities of which are the densely-crowded long lanceolate leaves. When in flower it bears some resemblance to the Sweet Chestnut. The fruit,

Common Mango (*Mangifera indica*).

which is a fleshy drupe, when fully ripe is somewhat kidney-shaped or oval, varying in size from that of a small hen's egg to a large goose's egg, in colour yellow or reddish, speckled with black, and containing a large flattened stone, the kernel of which is nutritious. There are several varieties of mango. Some have the flesh of the fruit full of fibres, and are on that account considered inferior; those that cut like an apple, and have few or no fibres, are the most highly esteemed. The fruit is eaten without any preparation, except peeling the outer rind off. Jellies, preserves, and tarts are made of the unripe fruit, and it is also pickled. Mango was introduced into Jamaica in 1782, and is now very generally cultivated in tropical and subtropical countries. The tree is ordinarily raised from seeds, but, as the finer varieties cannot be depended upon to come

true from seeds, they are increased by layering and inarching. *M. sylvatica*, besides being eaten when ripe and fresh by the natives of India, is dried and used medicinally. *Bouea burmanica* (formerly called *M. oppositifolia*), the fruit of which is of the size of a pullet's egg, is much esteemed in Burma.

Mangold-wurzel, or MANGOLD, a German name in general use in Britain and America to designate the varieties of the Common Beet (q.v.) cultivated in fields for the feeding of cattle—*Beta vulgaris* of the natural order Chenopodiaceæ. The field beets differ from the garden beets chiefly in being larger in all their parts, and coarser. They have large roots, which in some of the varieties are red, in others greenish or whitish, in some carrot-shaped, and in others nearly globular. The cultivation of mangold as a field-crop was introduced from France into England in 1786. At first, so little was its value known, that the leaves alone were used as food for cattle. Its importance, however, was soon appreciated, and it rapidly gained favour. It is much more patient of a high temperature than the turnip, liable to fewer diseases, and vastly more productive under favourable conditions. In highly-manured grounds in the south of England as much as from 60 to 70 tons to the acre have been raised; throughout the south of England it is generally admitted that it is as easy to grow 30 tons of mangold to the acre as 20 tons of Swedish turnips. The lower temperature of Scotland, however, does not admit of the crop being raised there to advantage. The mode of culture does not vary materially from that followed in raising turnips. The land in which the crop is to be planted receives a deep furrow in autumn; and, if it is quite free from perennial weeds, it is often previously well manured. Mangolds are sown both in rows on the flat ground and in drills raised by the plough—the former from 18 to 25 inches apart, and the latter from 25 to 28 inches wide. From 12 to 16 tons of dung with from 2 to 3½ cwt. of superphosphate, 2 to 3 cwt. common salt, and 2 to 3 cwt. nitrate of soda per acre are common dressings for mangolds. Indeed, this crop can hardly be over-manured. It requires 6 or 7 lb. of seed to the acre; and, as the grains are enclosed in a hard and rough coat, they are steeped in water for two days previous to their being planted, for the purpose of promoting a quick and regular 'braid.' The long red, the round red, and the orange and yellow globes are all favourite varieties in England. As soon as the plants are about 3 inches above ground, they are singled out by the hand, and their cultivation is afterwards the same in all respects as in the case of Swedish turnips. The crop should always be stored by the end of October, and should not be consumed till the following spring, by which time the roots have lost their tendency to produce scour in animals, and have greatly improved in feeding value. Care has to be taken not to injure the leaves or bulbs, as they are liable to suffer from 'bleeding.' The roots are stored in pits or 'clamps,' covered with straw and a little earth, as a protection in severe weather.

Mangonel. See BALLISTA.

Mangosteen, produced by *Garcinia Mangostana* (natural order Guttiferæ), is considered the most delicious and wholesome of all fruits. The tree, which is a native of the Moluccas, grows about 20 feet high in very regular symmetrical form. The leaves are large, oval, entire, deep dark green above with a dull lustre, olive-green below. The open flowers resemble those of a red rose, but have only four petals. The fruit, in size and shape, resembles a middling-sized orange; it is dark brown, spotted with yellow or gray, has a thick rind, and is divided internally by thin partitions

into cells. The pulp is soft and juicy, of a rose colour, refrigerant and slightly laxative, with a mixture of sweetness and acidity, and has an extremely delicate flavour. It may be eaten very freely with perfect safety, and is esteemed very beneficial in fevers. It is cultivated in Java and in the south-east of Asia; it has recently become common in Ceylon, and has been successfully introduced into other tropical countries.

Mangrove (*Rhizophora*), a genus of archichlamydeous dicotyledons, of the order Rhizophoraceæ. The name is also applied to plants of similar habit and habitat belonging to other orders. They are trees and shrubs, all tropical, and natives of coasts, particularly about the mouths of rivers, where they grow in the mud, and form a close thicket down to and within the margin of the sea, even to low-water mark, forming the characteristic mangrove-swamps so often described

A Mangrove-swamp.

by travellers and naturalists. Most species send down roots from their branches, and thus rapidly extend over large spaces, forming secure retreats for multitudes of aquatic birds, whilst crabs and shell-fish are also to be found in them in vast numbers. Their interlacing roots retain mud, seaweed, &c., and thus rapidly form soil and encroach upon the shallow sea; on the north coast of Java and elsewhere their geological importance is specially marked. The seeds have the peculiarity of germinating before the fruit has fallen, a long thick radicle proceeding from the seed, piercing its covering, and extending rapidly downwards. When the fruit drops, the stout heavy radicle pierces the mud, and the young tree is thus planted in the proper position forthwith. The fruit of the common mangrove (*R. Mangle*) is sweet, eatable; and its juice, when fermented, yields a light wine. The bark is rich in tannin, and is largely imported for tanning; it is exported from British East Africa and Queensland. The Chinese and East Indian mangroves (*Bruguiera gymnorrhiza*, &c.) are similar.—*White Mangrove* is *Avicennia* (q.v.).

Mangu, brother of Hulagu (q.v.). See MONGOLS.

Manhattan Island, an island in New York Bay, forming the New York City borough of Manhattan, and still containing the commercial nucleus of the city. Till 1874 the city did not extend beyond it; now it contains only a very small part of the total area. See NEW YORK.

Mania. See INSANITY.

Manica, a gold-field long worked by the Portuguese, 130 miles NW. of Beira, now divided between Southern Rhodesia and Portuguese East Africa.

Manichæus, or, more correctly, **MANI**, the founder of the sect of the Manichæans, was born in Babylonia, near Ctesiphon, about 216 A.D. His father Fatik is said to have belonged to the sect of the *Mughtasila* (Ablutioners), apparently a semi-Christian sect, akin to but not identical with the Mandæans; these latter, at least in their extant form, are later than Manichæism. On 20th March 242 A.D. Mani began to proclaim his new religion. He obtained some favour at the court of the Persian king, Sapor I., and then undertook long missionary journeys, returning to the court about 270. Pursued by the enmity of the Magians he was obliged to flee, was protected by the next king, Hormuzd, but under his successor, Bahram I., was abandoned to the hatred of his enemies, who put him to death about 276 and flayed his lifeless body. Till the 20th century, when Manichæan writings were discovered in Turkestan, Mani and his religion were known only from the testimony of their enemies—notably the Arabic work called *Fihrist*, and allusions and extracts in Epiphanius, Augustine, and Photius.

MANICHÆISM, though Mani its founder lived in Babylonia under the Persian dominion, is best regarded as a Christian heresy. It naturally uses much of the terminology of Persian religion, and in its later developments in Turkestan undoubtedly borrowed some things from the neighbouring Buddhism of Tibet. But Mani's face appears to have been turned to the West: the Christian elements which are obvious in Latin and Greek Manichæism are fundamental also to the Manichæism of Central Asia. What influenced Mani, however, was not orthodox Catholicism, but the forms of Christianity most prevalent in the Euphrates Valley during the 3d century, viz. the philosophy of Bardaisan (Bardesanes) and the heretic Church of the Marcionites. From the former Mani got the idea that this world is the result of a regrettable accident, whereby the pure Elements have been mixed with the Element that is naturally dark and foul; from the latter he derived his ascetic ethics and the organisation of the Manichees into the two classes of the *Elect*, who are world-renouncing monks and nuns, and the *Hearers*, who may marry and hold property. This organisation is also found in Buddhism, but it was fully developed among the disciples of Marcion (fl. 138 A.D.), and while traces of Manichæan polemic against the Marcionites survive, there are none of polemic against Buddhists.

The Manichees themselves start from the doctrine of the Two Roots and the Three Moments. The Two Roots, or, as we should say, the Two fundamental Principles, are Light and Dark; by the Three Moments they mean the Past, the Present, and the Future. Light and Dark are two absolutely different eternal Existences. Originally they were separate, as they should be. But in the *Past* the Dark made an incursion on the Light and some of the Light became mingled with the Dark, as it still is in the *Present*; nevertheless a means of refining this Light from the Dark was called into being and of protecting the whole realm of Light from any further invasion, so that in the *Future* the Light and the Dark will be happily separated.

It is right to begin a description of the Manichæan Religion thus, and not with theology proper, for to the Manichee the distinction between Light and Dark meant more than the distinction between God and Man or Devil. Mani taught an elaborate mythology, and Manichees prayed to 'God,' and to Mani as well as Jesus; but pure Light itself was divine to them, and in Manichæan writings it is often very difficult to distinguish between 'God' and the divine Light or a divine Man. The whole Manichee philosophy is materialistic as distinct from personal: what is saved of a man after death is

not what Christians would call 'himself' or his soul, but the particles of Light contained in him. The religious emotion of the Manichee was directed not towards men, but towards the Light imprisoned in men. Men were to some extent, and at second hand, in the image of God, but they were only a sort of pirated copy made by the evil, dark Archons to imitate the Messenger of Light that had appeared to them.

The Manichæan account of how the present state of things came about is shortly as follows. The Light and the Dark had existed side by side from all eternity without any commixture. Each Realm was self-contained and appropriately organised. In the Realm of Light dwelt the Father of Greatness with his Light, his Power, and his Wisdom. Persian-speaking Manichees called him *Zrvān*, i.e. the Eternal: his attributes were Sense, Reason, Thought, Imagination, good Intention—the qualities of a sane and intelligent mind. Opposite this blissful Realm or *terra lucida*, as Augustine calls it, is the Realm of the Dark, where everything was hostile and pestiferous. Its denizens suited its character: Mani represents them as groping about in aimless enmity with one another. Somehow once upon a time they became aware that there was something strange and yet pleasant outside their own region, and so the Ruler (or Archon) of the Dark invaded the realm of Light. Thus the event, to the issue of which is due the existence of the world we live in, came to pass through the unlicensed initiative of the Powers of Darkness.

To oppose this invasion the Father of Greatness called into being the Primal Man, clothed or armed with the Five Bright Elements, viz. Light, Wind, Fire, Water, and that pure Air which Mani seems to have regarded as the breath of Life. But the first consequence was disaster: the Primal Man was left unconscious on the field of battle and the Five Bright Elements were swallowed up by the Archons of Darkness. But the Father of Greatness sent powers which restored to the Primal Man his divine energy, so that he mastered the Archons and definitely arrested their invasion of the realm of Light. The problem now was not only how to turn the proper region of Darkness into a prison by encircling it with an impenetrable wall, but also how to extract the Light-substance which the Archons had swallowed. Out of what they immediately disgorged the Sun and Moon was formed, and out of their own bodies was formed the Earth, 'so that in rain and dew the pure Elements yet remaining in them might be squeezed out.' They yet had a certain power and volition, so to coax the Light out of them there appeared another divine being, the Messenger, and in a passion of desire for his beauty there exuded from them that which became plants and animals, and finally a Man, made in the image of the divine Messenger. The Messenger himself is the prototype of the true Prophets (called *Prēstags* in Persian and *Burkhāns* in Turkish), such finally as Mani was, who come to men in this dark world and tell them of the Light.

Man, i.e. Adam, thus formed by the Archons, was the image of the universe, of God and matter, of light and dark. But he lay on the ground inert and ignorant of his nature. So 'Jesus' appeared to him, awoke him, and made him realise that he had within him particles of Light. Jesus, it seems, was to the Manichee the Fruit which is man's food, 'hanging on every tree, produced by the energy and power of the air that makes the earth conceive' (Faustus *ap. Aug.* xx. 2). Adam, thus enlightened and energised, ate of the Tree of Life, and as Cumont (l. 49) says: 'By making Adam taste of the fruit of knowledge Jesus, and not the Tempter, revealed to him the depth of his misery. But man will know henceforth the way of enfranchisement. He must consecrate his life to keeping

his soul from all corporal defilement by practising continence and renunciation, so as to set free little by little from the bonds of matter the Divine Substance within him and disseminated throughout nature, and thereby to join in the great work of distillation (i.e. of the Light from the Dark) which God is occupied with in the Universe.'

It was further taught by Mani that Jesus had contrived a vast mechanism, like a water-wheel with twelve buckets, which takes up the light-particles from the souls and bodies of men when they die to the Moon, which thus waxes for fifteen days. While in the Moon the souls are somehow purged and purified by the Sun, and then the Moon empties itself of the purged Light, whereby it wanes for another fifteen days. The souls when purged are gathered into the Column of Glory (apparently the Milky Way), and so is gradually formed the Perfect Man (see Ephesians, iv. 13). When all the Light that can be distilled has been taken out of the Earth and its inhabitants, the filthy remainder will be burned, like a bonfire, for 1468 years, and the ashes will descend into the realm of the Dark from whence they came. In the Future, therefore, all will be as it was in the beginning, and this World, which is essentially a sort of Smudge, the result of a regrettable accident, will have altogether disappeared.

Mani recognised a succession of Prophets of the Truth at divers times and in many countries, with whose doctrine he believed his own to be in essential accord. But Jesus in Mani's system occupies a peculiar position. He was the last of the series before Mani, but he is more than that. To Mani Jesus was a Divine Being, who had 'appeared in Judæa' but was never born of woman; the Christians believed that this Jesus had been really crucified, but this was their carnal error. Of the true Jesus Mani regarded himself as the apostle, as the 'Paraclete' whom Jesus had foretold. 'Jesus' further signified to the Manichees Divine Redemption of man, Divine nourishment for man, accompanied somehow by the almost inconceivable idea of Divine suffering for man—and all this effected by 'Jesus who appeared in Judæa.' These are specifically Christian ideas; and though the Jesus revered by Mani has a different nature from the Jesus Christ of orthodox theology the same historical personage is meant. This unique position given to Jesus in Manichæan religion does make it a form of Christianity, however heretical or inconsistent. The Manichees of Chinese Turkestan invoked Jesus along with Mani in their prayers: we do not find that they invoked Zoroaster or the Buddha.

As explained above, the Manichees were divided into Elect Righteous initiates (*Zaddīks*, *Zendīks*) who abstained from all marriage and property, and the Hearers who lived in the world. The Elect might not sow or reap, or even prepare their food, for fear of hurting the Light contained in it: one chief religious duty of the Hearers was to feed the Elect, whose partaking of food given in alms was of benefit to the donor. The Hearers were, of course, the large majority of the Manichees; St Augustine was one for nine years (373–382 A.D.). Since 1911 we have possessed a document which shows us this Religion as a system of life for the ordinary Hearers. This is the *Khuastuanift*, or Confession, edited by Professor A. von Le Coq (*J.R.A.S.* for 1911, pp. 277–314); it contains a detailed confession of sins both in belief and practice, and so exhibits the Manichæan ideal better than any other surviving source.

The outward history of the sect is one of almost continuous persecution. Yet it spread rapidly from Persia and Mesopotamia to Syria, Turkestan, Northern Africa, and even Constantinople and Rome, drawing adherents from all sorts and condi-

tions of men and women. Both the Roman and Byzantine emperors enacted stringent laws against the Manichæans, the most severe being Valentinian III. and Justinian. Pope Leo the Great persecuted them in Rome, and in Northern Africa they were exterminated by the Vandals. But their peculiar doctrines are thought to have influenced many sects, as the Priscillianists, Paulicians, Bogomiles, Catharists, and Albigenses. In the 20th century archaeological researches in Central Asia, especially those of A. von Le Coq, P. Pelliot, and Aurel Stein, have shown that there was a well-organised Manichæan church on the confines of China in the 10th century. The documents found shed new light on their tenets and religious formularies: the *Khuastuaniſt* has been mentioned above. Besides this many fragments of MSS. in the peculiar Manichæan script were discovered, including portions of Mani's work called the *Shābuhrahgān*. Only insignificant scraps survive in the Mesopotamian Syriac in which Mani originally wrote, the MSS. from Chinese Turkestan being in a sort of Persian or in Turkish.

Mani is said to have been a skilful painter, and the Manichæes bestowed much care on the decoration of their sacred books. Many of the fragments collected by A. von Le Coq in Khotscho near Turfan in Chinese Turkestan are illuminated, and what is believed to be a portrait of Mani himself was found on a wall-fresco. It is probable that Manichæan art had some influence on the revived Persian art of the 13th century. The tale of Barlaam and Joasaph, so popular all over Europe and the Nearer East in the middle ages, is of Buddhist origin, but it appears to have reached the West through a Manichæan version.

See books by Beausobre (1734) and Baur (1831) for older opinions; for modern views see Flügel (1862); Cuimont's *Manichéisme* (1908-12); Bevan in *Ency. of Religion and Ethics* (1915); Alfario's *Écritures manichéennes* (1918-19); Mitchell's *Refutations of S. Ephraim* (1912-21); Burkitt's *Religion of the Manichæes* (1925). For the texts from Turfan see F. W. K. Müller, *Handschriften-Reste aus Turfan*, ii. (Berlin Academy's *Abhandlungen*, 1904); A. v. Le Coq, *Khuastuaniſt* (*J. Roy. Asiatic Soc.*, 1911), *Manichaica*, iii. (Berlin Acad. *Abhandl.*, 1922); W. Bang, *Khuastuaniſt* (*Muséon*, Louvain, 1923). For the Chinese texts see E. Chavannes and P. Pelliot, *Un Traité manichéen* (*J. Asiatique*, Paris, 1911-12). For the Art see A. v. Le Coq, *Die Buddhistische Spätantike in Mittelasien*, part ii. *Manichæan Miniatures* (Berlin, 1923).

Manila (by English people often spelt *Manilla*), chief town of the Philippine Islands (q.v.) and, till the blockade by a United States fleet in May 1898 and the subsequent American occupation of the Philippines, capital of the Spanish possessions in eastern Asia, stands on the east side of a wide bay on the SW. coast of Luzon, 650 miles SE. of Hongkong, with which it is connected by telegraph (1881). It is divided into two portions by the little river Pasig. On the south bank stands the sleepy old town (founded in 1571 by Legazpi), surrounded by crumbling walls, with tolerably wide straight streets crossing each other at right angles. Here are the archbishop's palace, numerous churches and monasteries, the cathedral, the university of San Tomas, Jesuit observatory, arsenal, and barracks. On the north bank are suburbs, Binondo, &c., the commercial and native quarters, and the ruins of the captain-general's palace. Looking forward to a rapid growth of population, the Americans have laid down a plan for the future extension of the city. It provides for the housing of 2,000,000, about ten times the population at the date of cession. The historical parts of the town are, on the whole, preserved, and it is recognised that 'the general

effect of the existing well-shaded narrow streets is picturesque, and should be maintained.' But wide spaces have been cleared for parks and new public buildings. These include a Capitol (for the elected Legislative Assembly, instituted 1907), surrounded by government offices, library, museum, observatory, laboratories, and hospitals; and to the north of the town the new university buildings. The native houses are generally constructed of bamboo, and thatched with the leaves of the nipa palm. Glass is not used in the windows, but the flat shell of a large oyster, and the window-frames all slide horizontally. This is to exclude the great heat, the mean for the year being 82° F.; but during the rainy season (May to November) it ranges from 65° to 68°. The population (mostly Tagálogs, with a few thousand Chinese, Americans, and Spaniards) is about 300,000. The people are fond of dancing and music; but their predominant passions are cock-fighting, betting, and gambling. The chief industry is the manufacture of cigars, which employs many thousands of women. The harbour is not very safe during south-west and north-east winds, although improvement works were on foot for ten years until suddenly stopped in 1889. These were resumed by the Americans, and much has been done. Since 1893 the city has been lighted by electricity. A new water-supply, from the Mariquina River, and a sewerage system, completed in 1909, have almost stamped out cholera and small-pox. Sugar, hemp, cigars and tobacco, and coffee account for the bulk of the exports, and cotton goods, rice, wine, silk, and flour figure most prominently amongst the imports. The trade is principally with China, the United States, and Great Britain, and is mostly carried in British vessels. The city has several times suffered from earthquakes (that of June 3, 1863, wrecking all the public buildings and killing several thousand persons), from typhoons (as in 1882, when half the city was wrecked), and also from great fires in 1893 and 1922. It shared in the revolution that began in 1896, and saw in its harbour the destruction of the Spanish fleet by the American commander Dewey in May 1898.

Manila Hemp. See ABACA.

Manin, DANIELE, an Italian patriot of Jewish descent, was born 13th May 1804 at Venice, studied law at Padua, and subsequently practised at the bar. From 1831 he became a recognised leader of liberal opinion in Venice. Previous to the outbreak of 1848 Manin was imprisoned for presenting a somewhat outspoken petition to the authorities; but on the promulgation of the news that Paris, Naples, and Tuscany were in revolution he was released in triumph by the populace, and was at once invested with supreme power. From the period of his election to the presidency of the Venetian republic Manin's energies were devoted to the organisation of the inhabitants for self-defence. During the annexation of Lombardy to Piedmont he laid down his authority; but on the defeat of the Sardinian army at Novara, 23d March 1849, he resumed it, and was the animating spirit of the entire population of Venice during the heroic defence of the city for five months against the besieging Austrian army. On the 24th of August Venice capitulated; but Manin, with forty of the principal citizens, being excluded from the amnesty, quitted the city. He retired to Paris, where he taught Italian, and where he died of heart-disease, 22d September 1857. See *Lives* by Henri Martin (Paris, 1859), Finzi (1872), Errera (1875), G. M. Trevelyan (1923).

Manioc, MANDIOC, or CASSAVA (*Manihot utilisima*), a plant of the order Euphorbiaceæ, a native of tropical America, much cultivated

there and in tropical Africa, Malaya, and the Dutch East Indies. Manioc, or *Mandioca*, is the Brazilian name, *Cassava* the West Indian; and in Peru and some other parts of South America the name is *Yuca*. The plant is shrubby, with brittle stems 6 to 8 feet high, and crooked branches, at the extremities of which are the large palmate leaves and green flowers. The root is tuberous, of immense size, weighing often as much as 30 lb. The milky, acrid juice which permeates every part of the plant is a deadly poison in its fresh state, owing to the presence of hydrocyanic acid, which is quickly dissipated by heat. The juice, inspissated by boiling, forms the excellent sauce called *Casareep* (q.v.), and fermented with molasses yields an intoxicating beverage called *Ouyouu*; whilst the root, grated, dried on hot metal plates, and roughly powdered, becomes an article of food, largely used in South America, and there very generally known as *Farina* (Port., 'meal'). It is made into thin cakes, like the oatmeal-cakes of Scotland, which are formed, however, not by mixing it with water, but by the action of heat softening and agglutinating the particles of starch. *Cassava* is also used in Europe and elsewhere for the manufacture of starch, alcohol, dextrin, and glucose, and to some extent as a cattle-food. The true starch of manioc, separated in the ordinary manner or by specially devised machinery from the fibre, is known in commerce as *Brazilian Arrowroot*. From it tapioca is made, by heating the undried starch on hot plates, and stirring with a fork; the starch-grains burst, the whole of the starch is converted into dextrin, and the whole agglomerates into small irregular masses. The name *Pearl Tapioca* is given to a product of potato starch; also to the granules of true tapioca broken up and graded according to size. Flake tapioca is made by stirring a thin layer of wet cassava starch on a hot plate.—Another species or variety of manioc is also cultivated, the roots of which, having their hydrocyanic acid mainly in the skin and cortex, are peeled and eaten raw, roasted, or boiled. This, the Sweet Cassava or Sweet Yuca (*M. palmata*), has the root of longer shape than the common or bitter cassava, and smaller. It endures cooler climates than the bitter cassava, and is cultivated in the Southern United States. *M. Glaziovii* yields Ceará rubber.—The manioc is easily propagated by cuttings of the stem, and is of rapid growth, attaining maturity sometimes in six months. The yield may be below two tons of fresh roots an acre on poor soil, or above fifteen on good. Some so-called tapioca is really a kind of Sago (q.v.).

Manipur, an Indian state in the east of Assam, occupying some 8500 sq. m. of for the most part heavily timbered mountain-land; pop. 384,000, collected most thickly in one valley, 650 sq. m., situated 2500 feet above sea-level. The men are incorrigibly lazy, but passionately fond of Polo (q.v.). The Manipuris combine Mongolian and Aryan characteristics, and are mainly Hindus in faith. The wild hill-men belong to the Naga and other stocks. A British political agent was established at the raja's court in the town of Manipur or Imphail (pop. 80,000) in 1835. In 1891 the chief-commissioner of Assam and others, seeking to remove a rebellious 'senapati' or commander-in-chief, were murdered. A British military expedition was sent, and the senapati and chief executed. The state was restored in 1907 to its native raja, a maharaja since 1918.

Manis. See PANGOLIN.

Manissa. See MAGNESIA.

Manistee', capital of a county in Michigan, is on Lake Michigan, at the mouth of the Manistee River, 135 miles NW. of Lansing; pop. 10,000.

Manitoba, a province of Canada, is bounded on the N. by Hudson Bay and the North-west Territories, on the S. by the United States, on the E. by Ontario, and on the W. by Saskatchewan. The area, originally about 15,000 sq. m., is now 251,832 sq. m., 178,100 sq. m. being added out of the North-west Territories (south-western Keewatin) in 1912. This total area includes over 20,000 sq. m. of water. The Red River rises in the United States, and flows almost due north about 85 miles through the province to Lake Winnipeg. Its principal tributary is the Assiniboine, which latter has again a large tributary, the Souris. Both the Red River and the Assiniboine are navigable for river steamers. The Winnipeg flows through the south-eastern part of the province from Ontario westwards to Lake Winnipeg. The Churchill and Nelson are the largest rivers; they drain into Hudson Bay, and possess an incalculable power in their waterfalls and rapids. The principal lakes are Winnipeg, 9460 sq. m.; Manitoba, 1775 sq. m.; South Indian, 1800 sq. m.; and Winnipegosis, 2086 sq. m. The country consists for the most part of a level plain, with occasional undulations. The summer mean temperature is 65° to 70° F.—nearly the same as in the state of New York. In winter the thermometer occasionally sinks to 30°, 40°, and even 50° below zero; but these extreme temperatures are not prolonged, and the bright and dry atmosphere and continued sunshine compensate for the low temperature. The cold is not so much felt as in many countries with a higher temperature and a more humid atmosphere. Very little snow falls on the prairies, the average depth being about 18 to 24 inches; the native horses graze out of doors all winter. Ploughing generally begins during April. The harvest takes place in August and September. Trees are found along the rivers and streams, and in greater abundance in the eastern and northern parts of the province; but Manitoba is not well wooded.

The population, in 1901 255,211, was in 1921, on its extended area, 610,118 (13,869 Indians); Presbyterians outnumbering the Methodists, Anglicans, or Roman Catholics. Among the principal cities and towns are Winnipeg, Brandon, St Boniface, Portage la Prairie. The chief industry is agriculture; the soil is of remarkable depth and fertility, and in favourable seasons the crops are large. Manitoba wheat and flour are regarded as the finest in the continent, if not in the world. Manitoba wheat is eagerly sought by American millers, notwithstanding duty, to mix with their own softer wheats. Other crops (oats, barley, and flax) succeed admirably. Vegetables are unusually prolific and of great size. Wheat-growing was for a time the staple industry; but the farmers are now turning their attention more to mixed farming, including dairy-farming and the raising of cattle and sheep. Fruit-growing is not carried on to any extent, although many of the smaller varieties—such as the strawberry, black and red currant, raspberry, gooseberry, and cranberry—appear to be indigenous. Apples are grown to a small extent, and the native plums are of excellent quality. In minerals the province is not very rich, but lignite is found in southern Manitoba. Copper and a little gold and silver are got. Manufactures of various kinds are increasing; and Winnipeg is to a large extent the distributing centre for the western part of the Dominion. The city has an ample supply of cheap power from the rapids and falls on the Winnipeg River about 60 to 80 miles north-east. Big game is still found in the less accessible parts—moose, elk, and some other kinds of deer, as well as bear. Small game is plentiful, principally prairie-chicken and wild-duck. Close seasons are provided for the protection of all the

principal wild mammals and birds. A considerable fishing industry is carried on in the rivers and lakes, and white-fish and pickerel are caught in large quantities. The white-fish of Lake Winnipeg are of superior quality.

The government is administered by a lieutenant-governor (appointed by the governor in council), an Executive Council, and an elected Legislative Assembly of fifty-five members. There is only one House of Parliament in Manitoba. The province sends six members to the Dominion Senate and seventeen to the House of Commons. A local Education Act in 1890, establishing rate-supported non-sectarian schools, abolished denominational education, and caused friction with the Roman Catholics, who had hitherto possessed separate schools; but an amending act in 1897 was accepted as a compromise, though it did not destroy the essential features of the non-sectarian system. A system of savings-banks in connection with the schools was established in 1899. There is a normal school for teachers at Winnipeg. The University of Manitoba at Winnipeg, which has several affiliated colleges, was in 1901 reorganised as a teaching university.

In Manitoba the Dominion government has offered free grants of land—160 acres—on homesteading conditions, to every male settler above eighteen years of age, and to every female who is the head of a family. There is still a considerable area of government land undisposed of in the north-west and north-east. Various companies have a considerable quantity of land for sale in different parts of the province.

Manitoba is in communication by rail with the Atlantic and the Pacific, and with all parts of Canada and the United States. The Canadian Pacific Railway—completed in 1885—has been of immense advantage to the province. The first railway to Manitoba, a continuation of the United States system to Winnipeg, was opened in 1879. The Grand Trunk Pacific, through Manitoba, Saskatchewan, and Alberta to British Columbia, was completed in 1914. A network of railways covers the southern settled region. The Hudson Bay Railway to Port Nelson, begun in 1911, runs through the northern extension of Manitoba.

Manitoba formed a portion of the territory under the control of the Hudson's Bay Company. The first agricultural settlement was formed in 1812, under the auspices of the Earl of Selkirk, who took out a party of Highlanders in that year. They were mainly located at Kildonan, on the Red River, just north of the site of the present city of Winnipeg. In 1868 the company gave up its exclusive rights to the government of the territory on certain conditions, among others a money payment of £300,000 and a considerable grant of land. The province was constituted by an act passed in 1870. The Riel rebellion of 1869-70 arose out of a feeling of some of the inhabitants that their position and rights had not been sufficiently considered in the transfer already mentioned. The rising collapsed in 1870 on the arrival at Fort Garry, the site of the present city of Winnipeg, of the expedition under Wolseley. Most of the leaders in the rebellion were subsequently amnestied. The progress of Manitoba from an agricultural point of view has been remarkable, but its political history has been comparatively uneventful, excepting for the existence of occasional friction between the provincial and Federal authorities in connection with railway extension and the school question. Its area was more than trebled in 1912. Female suffrage (with eligibility to parliament) passed in 1916.

the official Dominion and provincial year-books, and books named at CANADA.

Manitou. See ANIMAL-WORSHIP.

Manitou, a summer-resort at the base of Pike's Peak, Colorado, 6296 feet above the level of the sea. It is the Saratoga of the west, with soda springs and several large summer hotels.

Manitoulin Islands, a chain of islands separating Lake Huron from Georgian Bay. The principal are Grand Manitoulin (80 miles by 28), Cockburn Isle, and Drummond Isle; the last belongs to Michigan, the rest to Ontario. All are irregular and striking in their natural features, and Grand Manitoulin and Cockburn are covered with great pine-forests.

Manitowoc', capital of Manitowoc county, Wisconsin, lies at the mouth of the Manitowoc River, on Lake Michigan, 73 miles N. of Milwaukee. It has a good harbour, with shipbuilding, lumber-sawing, and manufactures of cigars, metal goods, &c. Pop. 18,000.

Manka'to, capital of Blue Earth county, Minnesota, on the right bank of the Minnesota River, 86 miles SW. of St Paul. Three lines of railway pass, and small steamboats can ascend as far as this point. The city contains a state normal school, Roman Catholic college, &c., and has varied manufactures. Pop. 12,000.

Mann, HORACE, American educationist, was born at Franklin, Massachusetts, 4th May 1796, graduated at Brown University, and studied law. He was elected to the legislature of Massachusetts in 1827, and succeeded in founding the state lunatic asylum. Removing to Boston, he was elected (1833) to the state senate, of which he became president. After editing the revised statutes of the state, he was for eleven years secretary of the Board of Education. He devoted his whole time to the cause of education, working usually fifteen hours a day. In 1843 he made a visit to educational establishments in Europe, and his Report was reprinted both in England and America. In 1848 he was elected to congress, as the successor of John Quincy Adams, whose example he followed in energetic opposition to the extension of slavery. In 1853 he accepted the presidency of Antioch College, at Yellow Springs, Ohio, where he laboured until his death, August 2, 1859. See his *Life and Works* (5 vols. 1898), and Hindale's *Horace Mann and the Common School System* (1898).

Mann, THOMAS, German novelist, born at Lübeck, 6th June 1875, removed to Munich, where he worked for a time in an insurance office, and studied at the High School. A psychological realist and a constructive artist, he made his reputation with *Buddenbrooks* (1903), and maintained it with *Königliche Hoheit* (1909). Besides these he excels in short stories (*Der Tod in Venedig, Tristan*, &c.), and has written a play, political reflections, miscellaneous prose, and verse.—His brother, HEINRICH MANN, born at Lübeck, 27th March 1871, and educated at Lübeck Gymnasium and Berlin University, is also a novelist of note, playwright, and essayist. *Der Untertan*, assailing the Kaiser and his admirers, was denied publication till the revolution.

Manna, a saccharine exudation got from the manna ash (*Fraxinus Ornus*), cultivated for the purpose chiefly in Sicily and Calabria. In July or August the collectors make deep cuts through the bark to the wood near the base of the tree; and if the weather be warm and favourable, the manna oozes out slowly, and hardens in lumps or flakes, which are removed. Manna is a light porous substance, usually in stalactiform pieces, 1 to 6 inches long, crystalline, friable, yellowish in colour, with a honey-like odour and a sweetish,

somewhat bitter taste. It is used in medicine as a gentle purgative for young children. It consists of about 60 to 80 per cent. of Mannite (q.v.), about 10 per cent. moisture, a bitter substance, and other less important constituents. There are several other manna-yielding plants besides the ash, especially the manna-bearing Eucalyptus of Australia (*Eucalyptus mannifera*), which is non-purgative, and is a favourite sweetmeat with the children of that country. Small quantities are found on the common Larch (q.v.) in some districts; this kind is known under the name of manna of Briançon.

The manna of the Israelites Ehrenberg identified with the saccharine substance called *Mount Sinai Manna*, produced in that region by *Tamarix mannifera*, a species of Tamarisk (q.v.), from whose branches it falls. It does not, however, contain any mannite, but consists wholly of mucilaginous sugar. The exudation which concretes into this manna is caused by the punctures made in the bark by insects of the genus *Coccus* (*C. manniparus*), which sometimes cover the branches. It is a kind of reddish syrup, and is eaten by the Arabs and by the monks of Mount Sinai like honey with their bread. Others have supposed that the manna of the Jews was produced by a species of Camel's Thorn (q.v.).

Manners, a noble family of Northumbrian extraction, their ancestor, Henry de Maners, having in 1178 been lord of the manor of Ethale, or Etal, in that county. His descendant, Sir Robert de Manners, was governor of Norham Castle in 1327. In 1454 another Sir Robert de Manners was sheriff of Northumberland; in 1525 his grandson was raised to the earldom of Rutland; and in 1703 the tenth earl was raised to the dukedom. The eldest son of the third duke was the celebrated Marquis of Granby (q.v.). The chief seat of the family is Belvoir Castle, 7 miles W. by S. of Grantham, a large castellated pile, reconstructed by Wyatt, and commanding a splendid view. Crabbe was chaplain here. See works by Eller (1841) and Allen (1874).

Mannheim, the capital formerly of the Rhenish Palatinate, and now the chief trading-town in Baden, lies low in a fertile plain on the right bank of the Rhine, here 400 yards wide and joined by the Neckar, 53 miles S. of Frankfurt and 38 N. of Karlsruhe. The fortifications have been converted into gardens, and the town is remarkable for its cleanliness and regularity, the whole of it being laid out in quadrangular blocks. The palace, built in 1720-29 by the Elector-Palatine Charles Philip, is one of the largest in Germany, covering 15 acres, with a façade 580 yards long, and 1500 windows. The Schillerplatz is adorned with colossal statues of Schiller, Dalberg, and the actor and dramatist Iffland (1759-1814). A great river-trade is carried on, the harbour having been opened in 1875. There are manufactures of dyes, chemicals, machinery, flour, agricultural implements, iron, cigars, carpets, rubber, &c. Pop. (1875) 46,453; (1885) 61,273; (1919) 229,576. Mannheim is heard of as early as 705, but remained a mere village till 1606, when a castle was built by the elector-palatine, around which a town grew up, peopled chiefly by Low Country Protestant refugees. It was several times taken and retaken in the 17th century; totally destroyed by the French in 1689; rebuilt and strongly fortified; bombarded by the Austrians in 1795, and by French and British in the Great War on account of its chemical and aeroplane works.

Mannikin. See WEAVER-BIRD.

Manning, HENRY EDWARD, born 15th July 1808, at Totteridge in Hertfordshire, was educated at Harrow and Balliol College, Oxford, and, after taking a first in 1830, and resigning a post in the

Colonial Office, was made a fellow of Merton. He soon came to the front as an eloquent preacher. In 1833 he was appointed to a country rectory in Sussex, and married a lady whose sisters were the wives of Samuel and Henry Wilberforce. Mrs Manning died after about four years of married life. In 1840 Manning became Archdeacon of Chichester. But in 1851, deeply moved by the final decision in the 'Gorham Case' (q.v.), he left the Church of England and joined the Church of Rome. His advancement in that communion was rapid from the first; having been ordained priest, he studied for some years in Rome, and in 1857 he founded the congregation of the Oblates of St Charles Borromeo at Bayswater, London. He was made provost of Westminster, and in 1865, on the death of Cardinal Wiseman, was promoted to be Archbishop of Westminster. At the Ecumenical Council of 1870, Manning was one of the most zealous supporters and promoters of the infallibility dogma; and, named cardinal in 1875, he continued an influential leader of the Ultramontane section of the church. Besides being the foremost spirit in most Catholic movements in England, he took part in many non-sectarian good works designed to better the social life of the people, such as the temperance movement; and he was a member of the Royal Commissions on the Housing of the Poor (1885) and on Education (1886). Before his secession to Rome, he published several volumes of powerful sermons; his subsequent writings were mainly polemical. He revised a number of articles in this work. A devout prelate, a churchly statesman, and a practical reformer, he died 14th January 1892. The Life by Purcell (1896), which was considered hardly fair to his memory, and provoked controversy, is supplemented by Leslie's (1921).

Manning, ROBERT. See BRUNNE, ROBERT OF.

Mannite, $C_6H_8(OH)_6$, is a peculiar saccharine matter which forms the principal constituent of Manna (q.v.); it is also found in several kinds of fungi, in asparagus, celery, onions, &c. It is most readily obtained by digesting manna in hot alcohol.

Manny, SIR WALTER DE, born in Hainault, followed Queen Philippa to England, fought well by land and sea for Edward III. against Scots, Flemings, and French, received broad lands as Lord de Manny, founded the Charterhouse monastery, and died in London, 15th January 1372.

Manoa. See EL DORADO.

Man-of-war. See NAVY.

Man-of-war Bird. See FRIGATE BIRD.

Manometer (Gr. *manos*, 'thin,' 'rare') is properly an instrument for measuring the rarity of the air or of other gases; but the name is most frequently applied to instruments for indicating the elastic pressure of gases, which is approximately, for each kind of gas, inversely proportional to its rarity, or directly proportional to its density. The several kinds of Barometers (q.v.) are really manometers, and so is the steam-gauge of a Steam-engine (q.v.). The name manometer is also given to piezometric tubes for measuring local pressures in liquids (say, flowing in a pipe) by the height to which the liquid is forced up the tube, this height corresponding to the difference between the internal pressure and the external atmospheric pressure.

Manor, in English law, denotes the land held by a body of tenants under one seignory or lordship. Manors were probably formed by the gradual establishment of feudal rights over free townships and subject communities of villeins or serfs; but, according to legal theory, the lord derives his rights from the king or from some superior lord. In a fully-organised manor the local customs are enforced by three courts: a Court Baron for the

free tenants, who are emphatically the *barones* or men of the manor; a Customary Court for the copyholders, who hold by base or customary tenure; and a Court Leet, in which officers are elected and minor offences punished. The lord's demesne includes lands occupied by himself and by his tenants-at-will, including customary tenants. Freehold lands do not form part of the lord's demesne; but free tenants are essential to the existence of a manor. Where the services of free tenants have been allowed to pass into desuetude the manor survives as a 'manor by reputation,' but the Customary Court is kept alive for the purpose of recording acts and events which affect the title to copyhold lands, and of collecting the quitrents, fines, &c., which are payable to the lord. No new free tenure can be created in England since the statute *Quia Emptores*, passed in 1290; all existing manors, therefore, must trace their origin from before that time. The king himself was lord of many manors in right of his crown; and these are called manors of ancient demesne, to distinguish them from lands which fell casually into the king's hands by forfeiture or otherwise. Manors closely resemble the feudal estates known to the law of Scotland. In the United States there is no such institution.

See FEUDALISM; Vinogradoff, *The Growth of the English Manor* (1905); Hone, *The Manor and Manorial Records* (1906); B. and S. Webb, *The Manor and the Borough* (1908).

Manrent (or MANRED), BONDS OF, agreements which used to be entered into in the Highlands of Scotland between the greater and lesser magnates, where protection on the one hand was stipulated in return for allegiance on the other.

Mauresa, a town of Spain, on the Cardoner, 41 miles NW. of Barcelona. It has a fine church (1020-15th century), the cave of Ignatius Loyola, and manufactures of cotton, broadcloths, brandy, &c. Pop. 27,000.

Mans, LE, once capital of Maine, and now of the department of Sarthe, 132 miles SW. of Paris. The cathedral, 390 feet long, has a Romanesque nave of the 11th and 12th centuries, and a matchless Pointed-Gothic choir of the 13th century, 104 feet high, with splendid stained glass. In the right transept is the monument of Berengaria, Cœur-de-Lion's queen. There are two other interesting churches, and both prefecture and seminary occupy old conventual buildings, the former comprising also a museum and a library. Le Mans does a large trade in poultry and clover-seed, and manufactures candles, woollens, lace, and soap. Pop. (1872) 42,654; (1911) 69,361; (1921) 71,783. The *Cenomanum* of the Romans, and the birthplace of Henry II. of England, Le Mans witnessed in 1793 the dispersion and massacre of 10,000 Vendéans, and in 1871 the defeat of 100,000 Frenchmen under Chanzy by Prince Frederick-Charles.

Mansard Roof, a form of roof, invented by the French architect François Mansard (1598-1666), is constructed with a break in the slope, so that each side has two planes, the lower being the steeper. It has the advantage of giving more space than usual for living rooms.

Mansard Roof.

Mansarowar, or MANASAROWAR, or TSO-MAYANG, a lake of Tibet, on the north slope of the Himalayas, in long. 81° 30' E., over 15,000 feet high, receives the Tage-tsangpo, the source of the Sutlej. It is noted in Hindu sacred legends, and is a place of pilgrimage for Hindus and Tibetans. The drainage into and out of Langak-tso is now normally underground. It lies between the sacred

mountain Kailas (20,300 feet) and Gurla-Mandhata (25,350). See Hedin's *Trans-Himalaya* (1909).

Manse, the dwelling-house of a minister of the Church of Scotland, in popular use applied also to that of a dissenting minister, though no legal right exists in the latter case. In the Established Church every first minister of a rural parish is entitled to a manse, which the heritors or landed proprietors in the parish are bound to build and uphold; and he is also entitled, as part of the manse or dwelling-house, to a stable, barn, and byre. The manse must, by statute, be near to the church. When a manse has been built or repaired by the heritors it becomes a free manse, and all ordinary repairs have to be done at the charges of the minister. Decree to the effect that a manse is 'free' may be given by the sheriff, and stands good for fifteen years, or until the appointment of a new minister. It has been judicially decided that a minister has a right to let his manse at a rent for two months in summer.

Mansel, HENRY LONGUEVILLE, Dean of St Paul's, was born at Cosgrove rectory, Northamptonshire, October 6, 1820. Educated at Merchant Taylors' School and St John's College, Oxford, he became Reader in Moral and Metaphysical Philosophy in 1855, and Waynflete professor in 1859. Appointed regius professor of Ecclesiastical History, and canon of Christ Church, Oxford, in 1867, he was made Dean of St Paul's in 1869. He died 31st July 1871. The pupil and continuator of Hamilton (q.v.), he differed from him in holding that there is immediate cognition of the conscious ego; he went beyond him in emphasising the Relativity of Knowledge (q.v.) in the province of theology—alleging that we have no positive conception of the attributes of God (see CONDITION). The agnostic tendency of this doctrine created violent controversy. His published works are Aldrich's *Logic*, with Notes (1849); *Prolegomena Logica* (1851); article 'Metaphysics' in 8th edition of the *Encyclopædia Britannica* (1857), afterwards published separately; *The Limits of Religious Thought* (Bampton Lectures, 1858); *The Philosophy of the Conditioned* (1866), in reply to Mill's *Review of Hamilton's Philosophy*; and lectures on *The Gnostic Heresies*, edited by Lightfoot in 1874, with Life of Mansel by the Earl of Carnarvon. He was co-editor, with Professor Veitch, of Sir William Hamilton's *Lectures*. See Dean Burgon's *Lives of Twelve Good Men* (1888).

Mansfeld, COUNTS OF, an old German noble family (founded circa 1060), whose ancestral castle stood at the east end of the Harz Mountains, 14 miles NW. of Halle. Two members of the family have acquired historical reputation. COUNT PETER ERNEST L., afterwards elevated to the rank of a prince, was born on 15th July 1517. Having taken part in Charles V.'s expedition against Tunis, and distinguished himself afterwards at the siege of Landrecies, he was made by the emperor governor of the duchy of Luxemburg. But in 1552, whilst raiding in Champagne, he was taken prisoner by the French, and not ransomed until 1557. He fought against them again at St Quentin. On the outbreak of the revolt in the Low Countries he made a name as one of the cleverest generals in the Spanish service. Having been sent by Alva to the assistance of the French king against the Protestants, he covered himself with glory at Montcontour (1569). He subsequently took part in many sieges and military operations in the Netherlands, and acted for a while as governor of the Spanish Low Countries. In 1597 he retired to Luxemburg, where he had gathered a valuable collection of antique art, and died there on 22d May 1604.

His illegitimate son, PETER ERNEST II., usually called Count Ernest von Mansfeld, was one of the most prominent military leaders during the Thirty Years' War (q.v.). Born at Luxemburg in 1580, he served his apprenticeship to war in the Austrian service in Hungary and in the Juliers dispute. As part of his reward he was promised his father's possessions; but when it came to the pinch, they were refused to him. This converted Mansfeld into an implacable enemy, and he went over to the side of the Protestant princes. He assisted the Duke of Savoy against the Spaniards (1613-17), and in 1618 was despatched to Bohemia, to aid the Count-Palatine Frederick, and captured Pilsen and other strongholds. But the disaster of the Weissenberg compelled him to retreat to the Palatinate, from which he carried on for nearly two years a semi-predatory war on the imperialists, defeating Tilly at Wiesloch (April 1622). When Frederick abandoned the struggle, Mansfeld, with his chosen ally Christian of Brunswick, a swashbuckling adventurer like himself, fought his way through the Spanish-Austrian forces to take service for the United Netherlands, beating Cordova at Fleurus (29th August). At the bidding of his new masters Mansfeld chastised the Count of East Friesland, and then, dismissing his army, retired into private life at The Hague. But in 1624 he resumed active work again at the solicitation of Richelieu. With an army of 12,000 men, raised mostly in England, he renewed the struggle on the Lower Elbe, till on 25th April 1626 he was crushingly defeated by Wallenstein at the bridge at Dessau. Once more raising a force of 12,000 in Brandenburg, with these and 5000 Danes he marched by way of Silesia to join hands in Moravia and Hungary with Bethlen Gabor of Transylvania. But the French and English subsidies failing, on which he relied for pay for his men, he was making his way to Venice with a few officers to raise fresh moneys when he fell sick and died, standing, clad in full panoply and supported by two attendants, at Racowitza, near Serajevo in Bosnia, on 29th November 1626. Count Ernest, a soldier of fortune, was the idol of his lawless soldiery, whom he frequently allowed to plunder and raid to their heart's content, so that they were a terror to friends as well as foes.

Mansfield, a municipal borough (since 1891) of Nottinghamshire, in Sherwood Forest, 17 miles N. of Nottingham. Its grammar-school (1561) has been rebuilt; and there are a memorial cross (1850) to Lord George Bentinck, a town-hall (1836), an interesting parish church, &c. Mansfield stands in the centre of a manufacturing and mining district, and has manufactures of lace-thread and iron. Pop. (1851) 10,012; (1911) 36,888; (1921) 44,418.

Mansfield, capital of Richland county, Ohio, stands on an elevated site, 155 miles NE. of Cincinnati, and contains iron-foundries and manufacturing of flour, agricultural implements, stoves, tiles, &c.; pop. 28,000.

Mansfield, KATHERINE, writer of short stories, was born (Kathleen Beauchamp) in 1889 in New Zealand, a daughter of Sir Harold Beauchamp of Wellington. She published from 1911 onwards. In 1913 she married Mr Middleton Murry the critic, and became one of the most distinguished reviewers in *The Athenæum*. With *Bliss* (1920) she stepped into the front rank of writers, the nearest perhaps to Tchekhov that English literature could show. She wrote with an amazing intensity, and had an unearthly gift for the significance of minute happenings. In *The Garden Party* (1922) again was seen the like power of sensitive expres-

sion in few and simple words. She died 9th January 1923. Posthumous volumes of short stories, *The Dove's Nest* and *Something Childish*, appeared in 1923 and 1924; and a volume of *Poems* in 1923.

Mansfield, WILLIAM MURRAY, EARL OF, Lord-chief-justice of the King's Bench, was the fourth son of Andrew, Viscount Stormont, and was born at Perth, 2d March 1705. From Westminster he passed to Christ Church, Oxford, graduated M.A. in 1730, and was called to the bar the following year. He soon acquired an extensive practice—mainly, it would seem, on account of his facility and force as a speaker, for neither then nor at any subsequent period of his career was he reckoned a very erudite lawyer—and was often employed on appeal cases before the House of Lords. In 1743 he was appointed Solicitor-general, entered the House of Commons as member for Boroughbridge, and at once took a high position. In 1746 he acted, *ex officio*, as counsel against the rebel lords, Lovat, Balmerino, and Kilmarnock; was appointed Attorney-general in 1754; and at this time stood so high that, had not the keenness of his ambition been mitigated by a well-founded distrust of his fitness for leading the House, he might have aspired to the highest political honours. He became Chief-justice of the King's Bench in 1756, and, contrary to usage, also a member of the cabinet; and entered the House of Lords under the title of Baron Mansfield of Mansfield, in the county of Nottingham. Although he was impartial and tolerant as a judge, his opinions were not those of the popular side, and accordingly he was exposed to much abuse and party hatred. Junius bitterly attacked him, and during the Gordon riots of 1780 his house, with all his books and papers, was burned. The aged judge declined with much dignity to be indemnified by parliament. In 1776 Murray was made Earl of Mansfield. Age and ill-health forced him to resign the Chief-justiceship in 1788. He died, 20th March 1793, when the title devolved upon his nephew, Viscount Stormont.

Mansfield College, a Congregationalist theological college at Oxford (q.v.), not included in the university.

Mansion, or **HOUSE**, in astrology, each one of the twenty-eight divisions of the ecliptic, occupied by the moon on successive days; also that sign of the zodiac in which each planet was supposed to have most influence; or one of twelve portions of the sky divided by great circles through the north and south points of the horizon.

Mansion, COLARD, a Bruges printer, for a time the partner, perhaps the teacher, of Caxton (q.v.).

Mansion House, the official residence of the Lord Mayor of London, was built on the site of the Old Stocks Market in 1739. It is an oblong building, and at its farthest end is the Egyptian Hall. Four hundred guests can dine in this grand banquetting-room, which was designed by the Earl of Burlington from the description of an Egyptian chamber given by Vitruvius. All the great banquets, public and private, given by the Lord Mayor take place here, and there are also fine ball and reception rooms. At the close of the exhibition of 1851 the Corporation of London voted £10,000 to be expended on statuary for the adornment of the Mansion House; and there is also a fine gallery of portraits and other pictures. Among its curiosities may be mentioned a state bed, and a kitchen and cooking utensils of vast size. The Mansion House is too modern to possess much historical interest; but the Wilkes riots frequently took place in its neighbourhood during the mayoralty of Wilkes's friend, Brass Crosby. It is often a centre for the collection of money for sufferers from disasters and

unemployment and for memorials to heroic worth. See a history by Sydney Perks (1922).

Manslaughter is the crime of unlawful homicide without malice aforethought. Homicide, or the infliction of death, is not a crime when it is done in self-defence against unlawful violence, or when it is done in the execution of the sentence of a court of justice. Thus one whose life is endangered by the violent attack of a madman, and who kills the madman, commits homicide, but is innocent of manslaughter. So, too, is the executioner who hangs a convicted murderer. Homicide is unlawful, and amounts to manslaughter when, without being justified in any such manner as has been exemplified above, it is committed with the intention to cause physical injury; or is the result of culpable negligence or omission to perform some legal duty; or is the result of an accident occasioned by some unlawful act. Thus, if one man strike another without intending to kill him, and the blow prove fatal, the striker is guilty of manslaughter; or if, where it is the duty of the master of a ship to keep a lookout for small boats in the ship's way, a boat is run down and its occupants drowned in consequence of the absence of a lookout upon the ship, the master of the vessel is guilty of manslaughter; or if a man is engaged in an unlicensed manufacture of dynamite, and by an accidental explosion of the dynamite another is killed, the manufacturer is guilty of manslaughter. When manslaughter is accompanied by malice aforethought, it becomes murder. See Sir James Stephen's *Digest of the Criminal Law*.

Manson, GEORGE, a Scottish water-colour painter, was born in Edinburgh on 3d December 1850. He served five years as a wood-engraver in the establishment of Messrs W. & R. Chambers, studying art in his spare hours morning and evening. His first picture which attracted attention, 'Milking Time,' was painted at Craigmillar Castle, between four and eight o'clock of the mornings of a whole summer. In 1871 he devoted himself to painting altogether, but his youthful hard study had permanently injured his health, and he died at Lympstone, Devonshire, 27th February 1876. His pictures are mostly from humble life; beauty and refinement of drawing and colour are their great charm. See a memoir by J. M. Gray, with photographs of his principal pictures (1880); also P. G. Hamerton's *Graphic Arts*.

Mansur. See ALMANSUR, KHALIF.

Mansûra, a town of Lower Egypt, on the Damietta branch of the Nile, 30 miles SW. of Damietta; pop. 50,000. The place was founded in 1220, and here St Louis of France was imprisoned in 1250.

Mantchuria. See MANCHURIA.

Mantegna, ANDREA, Italian painter, born in Vicenza in 1431, was the favourite pupil and adopted son of that tailor Mæcenas of painters, Squarcione. By studying the antique collections gathered together by his patron, especially from the study of the sculpture, Mantegna became imbued with the spirit of ancient art, and all his works bear the impress of the severe dignity and precision of his models. Grace and beauty were not the ideals that he aimed at; some of his pictures are positively ugly. A precocious genius, Mantegna set up an independent atelier when only seventeen years of age. Amongst his earliest works, done at Padua, are frescoes of saints in the church of St Antony, an altarpiece for St Justina, and most of the frescoes of St Christopher, and some of those of St James, in the church of the Hermits. Having married the sister of Giovanni and Gentile Bellini, he seems to have become estranged from Squarcione, and left Padua (1459). He painted an altarpiece, the 'Madonna and Angels,' for St

Zeno's church at Verona, and was induced by Lodovico Gonzaga, Duke of Mantua, to settle in his city. There he remained, with the exception of a visit to Rome (1488-90) to paint a series of frescoes (now destroyed) for Pope Innocent VIII., until his death on 13th September 1506. His greatest works at Mantua were nine tempera pictures representing the 'Triumph of Cæsar' (his masterpiece), 'The Madonna of Victory with Gonzaga,' 'Parnassus,' 'Defeat of the Vices,' 'Triumph of Scipio,' and 'Madonna between St John the Baptist and St Magdalene.' Like Leonardo da Vinci, Mantegna was something of a universal genius. He was an engraver and an architect, as well as a painter, and is said to have written poems and wielded the sculptor's chisel. His best plates bear the titles 'A Bacchanal Feast,' 'Descent from the Cross,' 'Entombment,' 'Resurrection,' 'Battle of the Titans,' and 'Roman Triumphs.' Mantegna's technical excellencies, his skilful foreshortening, masterly perspective, and austerity of form exercised great influence upon Italian art.

See Miss Julia Cartwright's *Mantegna and Francia* (1881); Yriarte's *Mantegna* (1900); and the great monograph by Paul Kristeller (1901).

Mantell, GIDEON ALGERNON, an eminent British palæontologist and geologist, was born at Lewes, in Sussex, in 1790; studied medicine; and practised successively at Lewes, Brighton, Clapham, and London, where he died in 1852. Though long suffering from a distressing spinal disease, the result of an accident, he pursued his studies with unabated zeal. He bequeathed his geological drawings to Yale College. His collections he sold to the British Museum in 1839 for £5000. Mantell's principal works are *Fossils of the South Downs* (1822); *The Fossils of Tilgate Forest* (1826); *Wonders of Geology* (1833), perhaps the most popular geological work ever written by an Englishman; and *Medals of Creation, or First Lessons in Geology* (1844). He was a very voluminous writer, no less than sixty-seven works and memoirs of his being enumerated in Agassiz and Strickland's *Bibliotheca Zoologica et Geologica*. His claims to a permanent place in the history of science rest mainly on his laborious investigations into the fossils of the Wealden beds. To him we owe the discovery and description of the four great Dinosaurian reptiles, the *Iguanodon*, *Hylæosaurus*, *Pelorosaurus*, and *Regnosaurus*.

Mantes, a town in the French department of Seine-et-Oise, on the left bank of the Seine, 36 miles by rail WNW. of Paris. It has a striking tower (1344) and a beautiful church, a reduced copy of Notre Dame at Paris. The ancient *Medunta*, a town of the Celts, Mantes in 1083 was sacked by William the Conqueror, who here received the injury that caused his death; and here too Henry IV. was converted from Protestantism. Pop. 10,000.

Manteuffel, EDWIN HANS KARL, FREIHERR VON, Prussian general and administrator, was born, of an old Pomeranian noble family, at Dresden on 24th February 1809. Entering the Prussian guards in 1827, he rose to be colonel by 1854, and three years later was nominated head of the military bureau at Berlin, a post which he held until 1865. Having been appointed commander of the Prussian troops in Sleswick, he protested against the summoning of the Holstein estates by marching his men into that duchy (June 7, 1866). On the outbreak of hostilities Manteuffel commanded a division of the army of the Main, which was destined to act against the south German allies of Austria. He took part in the battle of Langensalza (27th June), which brought about the capitulation of the Hanoverian army, and on 19th July succeeded Von Falckenstein as commander-in-

chief of the Main army, and by winning the battles of Werbach, Tauberbischofsheim, Helmstädt, and Rossbrunn over the Bavarians and others he brought that part of the campaign to a successful issue. He entered the war of 1870 as commander of the First Corps, but was soon promoted to the command of the First Army, which fought successfully at Amiens and other places. Transferred in January 1871 to the command of the army of the south, operating against Bourbaki, Manteuffel assailed the enemy's rear near Belfort, and drove 80,000 men across the frontier into Switzerland. When peace was proclaimed he was placed at the head of the army of occupation in France, and in 1879 was appointed imperial viceroy of the newly-organised province, Alsace-Lorraine. He died 17th June 1885. See Life by Keck (1889).

Manticore, a fabulous beast mentioned by Ctesias (q.v.), having a human head, lion's body, scorpion's tail, and porcupine's quills. A form of it sometimes appears in heraldry.

Mantineia, an ancient city of Arcadia, in the Peloponnesus, in a plain on the river Ophis. Here Epaminondas fell in the moment of a great victory over the Spartans, 362 B.C.

Mantis. This name is commonly applied to the various genera which constitute the family Mantidae of the insect order Orthoptera. They are chiefly to be distinguished by the long prothorax and the enlarged front legs, which are fitted for grasping. They are entirely carnivorous in habit, but do not actively pursue their prey; the insect waits patiently until a fly comes within reach, and then rapidly seizes it with its fore-limbs (see the illustration).

Mantis religiosa.

The attitude adopted while waiting for insects to come within reach has given to one species, plentiful in the south of Europe, the name of 'praying mantis' (*M. religiosa*). This creature, invested with supernatural attributes, figures prominently in Bushman mythology and folklore. One of the most remarkable forms of mantis is the Indian *Hymenopus bicornis*; it has a flower-like shape and a pink colour. The apparent petals are the much-flattened joints of some of the limbs as it rests quietly among foliage. It is supposed that the resemblance to an orchid-like flower may delude smaller insects into approaching near enough for the mantis to take advantage of its 'alluring' colours and shape.

Mantle. See GAS (LIGHTING AND HEATING BY). Mantles have also been used with oil-lamps.

Mantling. See HERALDRY.

Man-traps, formerly often indicated by the warning notice 'Man-traps and spring-guns set here,'

resembled gigantic rat-traps four feet long. It is, since 1827, illegal to set them save indoors between sunset and sunrise, as a defence against burglars.

Mantua (Ital. *Man'tova*), a fortified city of northern Italy, formerly capital of a duchy and now of a province, 36 miles N. of Modena and 22 S. by W. of Verona, occupies two islands formed by the Mincio, and stands in the midst of a marshy district, which, combined with its artificial fortifications, makes it perhaps the strongest fortress in Italy. But its situation makes it liable to malaria. It forms one of the four fortresses of the Quadrilateral (q.v.). The streets are spacious, the squares numerous, and the population comparatively small—36,633 in 1921. For this reason, and because of the numerous massive mediæval buildings, the town has a lifeless and gloomy appearance. Chief amongst the buildings are the fortress of the Gonzagas, erected in 1393–1406, and adorned with paintings by Mantegna; close by is the ducal palace, begun in 1302, which contains 500 rooms, many of them ornamented with paintings and designs of Giulio Romano; the Palazzo Te, outside the city walls on the south, the greatest monument to the skill of Giulio Romano as architect, painter, and sculptor; the cathedral of San Pietro, restored from designs by Romano; and the church of San Andrea, one of the finest Renaissance churches in Italy, containing the tomb of Mantegna, whose pupils adorned the walls with frescoes. The public institutions include an academy of arts and sciences, a library, a museum of antiquities, an observatory, archives, a botanical garden, a large military hospital, &c. Virgil was born at Pietole (anc. *Andes*), now a suburb of Mantua. The industries include weaving, tanning, and saltpetre-refining. The Jewish population is considerable. Mantua, an Etruscan town, was successively in the possession of the Romans, Ostrogoths, and Lombards before falling into the hands of the emperors, who gave it to the Marquis of Canossa. From him it passed to the Countess Matilda of Tuscany in 1052. After her death it was a free imperial city and joined the Lombard leagues against the Hohenstaufen emperors. The Buonacolsis made themselves masters of the city in 1247, but were ousted from power by the head of the Gonzaga (q.v.) family in 1328. This dynasty, the head of which was created duke by Charles V. in 1530, not only maintained themselves against their great rivals, the Visconti of Milan, but raised the city to the height of its splendour and renown. The last duke died childless in 1708, and his duchy was confiscated by Austria, who kept her hold of it down to 1866, except for two short periods (1797–99 and 1801–14), when it was in the possession of France. Mantua has endured at least three great sieges, by the Emperor Ferdinand II. in 1630, by the French in 1797, and by the Austrians in 1799. Here Andreas Hofer (q.v.) was shot in 1810.

Mantuanus (or SPAGNUOLI), BAPTISTA (1448–1516), the 'good old Mantuan' of *Love's Labour's Lost*, was a native of Mantua, who became general of the Carmelites. He wrote Latin eclogues long read in schools, translated by Turberville, and imitated by Spenser in the *Shepherd's Calendar*. See the edition by Dr W. P. Mustard (Phila. 1911).

Manu is the reputed author of the most renowned law-book of the ancient Hindus, the *Manu-Smṛiti* or *Mānava-Dharmaśāstra*. The ascription is apocryphal; for, in several passages of the Vedas (q.v.), as well as the Mahābhārata (q.v.), Manu is mentioned as the hero of the Hindu legend of the flood and as the progenitor of the human race; and, in the first chapter of the law-book ascribed to him, he declares himself to have been produced by Virāj, an offspring of the

Supreme Being, and to have created all this universe. Hindu mythology knows, moreover, a succession of Manus, each of whom created, in his own period, the world anew after it had perished at the end of a mundane age. The word Manu—akin to our ‘man’—belongs therefore, properly speaking, to ancient Hindu mythology, and it was connected with the renowned law-book, partly in order to impart to the latter the sanctity on which its authority rests, and partly because, as Bühler has proved, the extant work is a verified recast of an older law-book, now lost, the *Mānava-Dharmasūtra*, the manual of a particular Vedic school, the Mānavas, whose name indicates that they claimed descent from Manu. This work is not merely a law-book in the European sense of the word, it is likewise a system of cosmogony; it propounds metaphysical doctrines, teaches the art of government, and, amongst other things, treats of the state of the soul after death. The chief topics of its twelve books are the following: (1) creation; (2) education and the duties of a pupil, or the first order; (3) marriage and the duties of a householder, or the second order; (4) means of subsistence and private morals; (5) diet, purification, and the duties of women; (6) the duties of an anchorite and an ascetic, or the duties of the third and fourth orders; (7) the duties of a king as regards internal administration, foreign relations, and war; (8) judicature and law, private and criminal; (9) marital relations, inheritance, miscellaneous royal duties, and the duties of the castes of commoners and serfs; (10) mixed castes and the duties of the castes in time of distress; (11) penance and expiation; (12) transmigration and final beatitude. Bühler holds that the work, the date of which used to be given at 1200 B.C., was certainly extant in the 2d century A.D., and seems to have been composed between that date and the 2d century B.C. There are many remarkable correspondences between this work and the Mahābhārata, suggesting the use in both of common materials.

The laws of Manu were translated by Sir William Jones (1794). See also *The Ordinances of Manu*, translated from the Sanskrit, with introduction by Burnell, completed by Hopkins (1884); *The Laws of Manu*, translated with extracts from seven commentaries by G. Bühler (in ‘Sacred Books of the East,’ 1886).

Manure. Any material, whether of animal, vegetable, or mineral origin, which adds to the fertility of the soil has been generally regarded as manure. The application of stable and farmyard manure, as also the ashes of plants, &c., to the soil has been practised probably in all ages; but the scientific principles involved in this ancient practice were but little understood until more recent times, when chemists, botanists, and physiologists set themselves the task of explaining to the agriculturist the changes which are ever taking place in the soil and in the plant itself. On virgin soils crops may be grown for years without much evident diminution in quantity or quality; but a period must come when there will be an exhaustion of one or more of the constituents of plants, and the soil can then be no longer regarded as fertile. That is to say, soils contain certain proportions of certain ingredients; and when these are abstracted by the plant and carried away in the form of crops, the soil must in time become exhausted. It then becomes necessary to add to the soil in the form of manure such constituents as the crops have removed in order that the land may regain fertility. When we consider that Soils (q.v.) are formed mainly from the weathering of rocks, it will at once be understood how it is generally unnecessary that manures should contain such things as magnesia, iron, alumina, &c. Speaking generally, the constituents which are removed by plants from soils,

the loss of which brings about that condition of ‘exhaustion,’ are compounds of nitrogen, phosphoric acid, and potash; and hence it is, in part at least, that farmyard manure is so universally regarded as the ‘stand-by’ of the agriculturist, for that material contains all those ingredients, and in a form easily assimilated by plants. It must not be overlooked, however, that possibly the chief advantage derived from the use of farmyard manure is that it adds humus or organic matter, which renders the soil more porous, increases its water-holding capacity, and renders it easy of reduction to a favourable state of tilth. Manures containing large proportions of organic matter, such as stable manure, wrack or seaweed, fish offal, &c., have value as plant-food; but their beneficial effects are largely due to the physical properties of the decaying organic matter which they contain.

The first *artificial* manure systematically used was probably bones, applied in the earlier periods, either in an unground condition or simply bruised. About the beginning of the 19th century, however, it was proved that fineness of division rendered bone more easily assimilated by plants; and further progress still was made when Liebig introduced the treatment of bone with sulphuric acid, whereby chemical division was realised. The relative importance of bones as a manure has decreased greatly.

Guano.—Peruvian guano was at one time imported from the Chincha Islands in enormous quantities; but the old deposits are practically exhausted, and the quality of the now available supply is comparatively poor (see GUANO). Ichaboe (off south-west Africa) guano is still imported, though in somewhat limited quantity; but it is much the richest available guano. The value of these guanos lies in the percentages of nitrogenous organic matter, ammonium salts, phosphates of the alkalies and of lime, and the potash salts which they contain. Some of the islands in the South Pacific yield supplies of guano, but these are almost purely phosphatic, owing to the abundant rainfall of that region having washed out all the ammoniacal salts. Liebig’s Guano and Liebig’s Meat Meal are by-products from the preparation of Liebig’s extract of meat. They are in a fine state of mechanical division, and are valuable sources of nitrogen and phosphates. Fish-guano is largely produced in Norway and the north of Scotland from fish offal (see GUANO). The process employed is essentially steaming to remove the oil, which is run off with the water; the solid residue is pressed and dried. The manurial constituents of this material are nitrogen and phosphates.

Dried Blood is another valuable source of nitrogen. Horn powder, shoddy and wool waste, leather raspings, &c. are also employed for the same purpose, but they are of much less value.

Phosphatic Substances are of two classes. Mineral phosphates are obtained from Florida, Carolina, Christmas Island, Algiers, and other places. They may be used directly as ‘ground mineral phosphate,’ or are more generally treated with sulphuric acid to form *superphosphate* ($\text{CuH}_4(\text{PO}_4)_2$), which is soluble in water, and therefore forms a quick-acting manure. Superphosphate is now widely used. The other common form of phosphatic manure is *basic slag*, a by-product from the manufacture of steel from phosphatic ores. It is used without any treatment beyond that of grinding to a very fine powder; 80 or 90 per cent. should pass through a sieve of 10,000 holes to the square inch. These manures are valued according to the quantity of phosphate they contain, which may vary from 15 per cent. in low-grade slag to 70 or 80 per cent. in high-grade mineral phosphate.

Sulphate of Ammonia is principally derived from

the destructive distillation of coal and shale (see GAS and PARAFFIN). Its value depends upon the percentage of ammonia which it contains. The normal commercial product, 95 per cent. pure, contains 20 per cent. of nitrogen, equivalent to 24 per cent. ammonia.

Nitrate of Soda or *Chile Saltpetre* is very extensively imported, and is sold on a basis of 95 per cent. nitrate, or '5 per cent. refraction'—i.e. not more than 5 per cent. of impurities—equivalent to 15 per cent. nitrogen. It is found native in several districts of South America in an impure state, and is rendered marketable by a process of solution and re-crystallising. See NITRE.

Nitrate of Lime and *Calcium Cyanamide* are made by different processes, in both of which atmospheric nitrogen is fixed and rendered available as manure. Both are valuable manures, but the cyanamide is not suitable for application to cold, wet soils. Commercial nitrate of lime is about 75 per cent. pure, equivalent to 13 per cent. nitrogen. Commercial cyanamide contains 18 per cent. nitrogen.

Potash Salts are of the utmost service to plants. Carse or clay lands generally contain a sufficiency of potash, while medium and light soils require it to be added. Nitrate, sulphate, and muriate are all more or less employed in compounding potash manures (i.e. manures containing potash as one of their constituents), but kainit—an impure potash salt largely imported from Germany—is perhaps the most generally used when a dressing of potash only is desired.

Liquid Manure may be classed with farmyard manure, as it is now very commonly absorbed in the 'courts' by the straw, &c. Occasionally it is used in the liquid form on grass or stubble land.

Lime is not a manure in the strict sense, in that it is never applied with the object of supplying the particular element, calcium, which it contains. Its great value is in supplying a *base*. In its absence soils become acid, and the normal bacteriological processes of nitrification cease. Lime may be applied as carbonate—e.g. ground limestone or chalk—as oxide (quicklime), or as hydrate (slaked lime). See AGRICULTURE, BONE MANURES, COMPOSTS, ROTATION, SEWAGE, SLAG.

Manytch, a depression which in geologically recent times connected the Caspian with the Sea of Azov, and may still be regarded as the boundary between Europe and Asia. The river Manytch flows (when it is not a mere chain of salt lakes) WNW. to the Don. The eastern Manytch flows eastward from the watershed, until it is lost in the sands, or possibly sometimes reaches the Caspian through the Haiduk and the Kuma.

Manzanares, a town of the Spanish province of Ciudad Real, 100 miles S. of Madrid, in the La Mancha country, has an old citadel. The district produces saffron and wine. Pop. 16,000.

Manzanares. See MADRID.

Manzanillo, (1) a port of Mexico, on a fine bay opening to the Pacific, 41 miles WSW. of Colima, with which it is connected by rail. The country around is fertile. Pop. 4000.—(2) A port on the south coast of Cuba, with a good harbour, and export trade in valuable woods, sugar, &c.; pop. 60,000.

Manzanita, a name given to several Californian shrubs, species of *Arctostaphylos* (see BEARBERRY), which form dense thickets ('chaparral') on the mountain-sides. The berries are edible.

Manzikert, MANAZGERT, or MELAZGERD, in Armenia, N. of Lake Van, scene of the victory of Alp-Arslan (q.v.) over Romanus Diogenes in 1071.

Manzoni, ALESSANDRO, a great Italian writer, was born at Milan, March 7, 1785, of noble parents, through his mother grandson of the celebrated Marquis Beccaria. He published his first poems in 1806, married happily in 1810, and spent the next few years in the composition of the *Inni Sacri*, sacred lyrics, and a treatise on the religious basis of morality, by way of reparation for the unbelief of early youth. In 1819 he published his first tragedy, *Il Conte di Carmagnola*, a trumpet-blast of romanticism; the second, *Adelchi*, followed in 1822. Manzoni's first tragedy had the honour to be defended by Goethe, 'one genius having divined the other.' But the work which gave Manzoni European fame is his historical novel, *I Promessi Sposi*, a Milanese story of the 17th century (3 vols. Milan, 1825-6-7). The tale abounds in interesting sketches of national and local Italian customs and modes of life, portrayed with unflinching spirit and humour, while various grave historical events are narrated with force and grandeur of style, especially the episode of the plague in Milan. Manzoni's noble ode, *Il Cinque Maggio*, was inspired by the death of the great Napoleon. His last years were darkened by the frequent shadow of death within his household. He himself died at Milan, 23d May 1873, leaving to posterity the memory not alone of a great writer, but of a singularly noble and sincere man.

An edition of his works in 5 vols. was published in 1828-29, and his Letters were collected by Sforza (1875). The standard edition of the complete works (Hoeppli, Milan) includes his Letters edited by Sforza and Gallavresi (1913). See Bismara's *Bibliografia Manzoniiana* (Turin, 1875); Lives (Italian) by Albiani (1873), Bersezio (1873), Prina (1874), Pagni (1876), Gubernatis (1879), and Graf (1898); De Sanctis, *Manzoni: Studi e Lezioni* (1922).

Ma'oris, the native inhabitants of New Zealand (q.v.).

Maormor. See EARL.

Map (Lat. *mappa*, 'a towel'). A map is a delineation on a plane of the surface of the earth or of a portion thereof, exhibiting the lines of latitude and longitude, &c., and the forms and relative positions of the countries, mountain-ranges, rivers, towns, &c.; or it may be of the starry heavens, or of stars and constellations. As it is manifestly impossible correctly to represent a spherical upon a plane surface, geographers are consequently necessitated to resort to expedients in order to minimise or distribute the unavoidable distortion and disproportion. Hence the use of the various map projections or arrangements of the lines of latitude and longitude. The only true representation of the earth's surface, it is clear, is to be found on the *terrestrial globe*. This is inconvenient in form and necessarily too small in scale to serve the purposes effected by maps proper, which are usually produced on paper or other convenient plane surfaces, and a series of which, conjoined, form an *atlas*. A *hydrographical* map, specially representing oceans, seas, or navigable waters with their coasts, sandbanks, currents, lighthouses, depths, and other objects and information of importance to seamen, is usually constructed on Mercator's projection, and is called a *Chart* (q.v.). A special *topographical* map represents the details minutely and on a considerable scale. The Ordnance Survey (q.v.) of Great Britain and Ireland is a good example of such, and is produced on various scales. An *orographical* map shows the relief of the land surface. For this purpose Contour Lines (q.v.) are much more satisfactory than the old-fashioned hachures; and 'layers' coloured in a scale ranging (say) from dark green

for land near sea-level, through light greens and browns to dark browns for the highest hill-tops, present the character and details of a country vividly to the eye. In like manner a *bathygraphical* map shows depth of water, commonly by deepening shades of blue. A *bathyorographical* map is a combination of the two last. Maps may be constructed for special purposes, and are distinguished as physical, geological, political, military, statistical, historical, &c. See GEOGRAPHY, GEOLOGY, SURVEYING.

Officers of the Geological Survey (q.v.) insert in Ordnance Survey maps the boundaries of formations and other data of interest to geologists and miners. The geological maps thus made were long hand-coloured, but are now printed in colours. In like manner botanical maps have been constructed by ecologists, by indicating plant-formations upon an ordinary map.

Within the last century or so great improvement has been made in the art of map production or *cartography*, resulting in great clearness and the combination of a mass of information with artistic beauty. This is attained in some cases partly by the use of conventional signs or arrangements, such as the adoption of blue colour for coasts and water-courses, brown for mountain-ranges, and various tintings for the divisions, political or otherwise, and to distinguish the various natures of the surface, such as forest, arable, prairie, desert, differences of elevation, &c. The art of lithography has been an invaluable aid in all such cases. In Germany especially has this science-art been carried to the greatest perfection. Of late maps have been made by photographing the ground from aircraft, a method of use in difficult country.

The *scale* or definite relation of a map to the actual size of nature is indicated by a graduated line, showing by its divisions the number of kilometres, or miles, or yards corresponding to any space measured on the map. In comparing various maps by their scales, it is convenient to refer to the *scale of nature*, frequently indicated in proportional figures, thus—1 : 3,700,000 ; 1 : 500,000, &c.

The lines of *projection* on a map are essential for determining the positions of the parts, and indicate latitude, or distance north or south from the equator, and longitude, or distance east or west from any given line. These lines are called meridians, and are usually numbered from the meridian of Greenwich on English maps, and indeed on nearly all maps. Other first meridians in common use are those of Paris, Washington, and Ferro (see LATITUDE AND LONGITUDE). These distances are given in degrees, minutes, and seconds, as in other circle measurements. In choosing a projection, regard must be had to the purpose for which it is intended, and to the area to be represented. The errors inherent in a projection nearly imperceptible in a map of England might be fatal to its use in a map of Asia. In a map of the world equivalence of area is of less importance than freedom from distortion and correctness of relative position. There have been numerous forms of projection devised, including perspectives and approximative developments. Of these only the more familiar can be described here.

The plane on which the perspective map is drawn is supposed to pass through the centre of the earth, and, according to the distance of the eye, the projection is either of the first, second, or third of the following. (1) In the *orthographic* the eye is assumed to be at an infinite distance from the centre of the earth, so that all rays of light proceeding from every point in its surface are parallel and perpendicular. From the nature of this projection, it is evident that, while the central parts of the hemisphere are fairly accurately represented, the parts towards the

circumference are crowded together and diminished in size. On this account it is of little use for geographical purposes, but most suitable for maps of the moon. (2) In the *stereographic* the eye or point of projection is assumed to be placed on

Fig. 1.
Globular, or Equidistant Projection of a Hemisphere.

the surface of the sphere opposite the one to be delineated. If the globe were transparent, the eye would then see the opposite concave surface. Contrary to the orthographic, this method contracts the centre of the map, and enlarges it towards the circumference. Owing to the unequal area of the divisions, and the difficulty of finding the true latitude and longitude of places, this projection is not much employed. (3) In order to rectify the opposite effects of the two preceding, the *globular* projection, a modification of the two, is generally adopted. If we suppose the eye to be removed from the surface to a distance equal to the sine of 45° of the circumscribing circle, the projection is called globular. In other words, if the diameter of the sphere be 200 parts, it must be produced 70 of these parts in order to give the point of projection. All meridians and parallels in this projection are in reality elliptical curves; but as they approach so nearly to circular arcs, they are very rarely shown otherwise.

The construction of the globular or equidistant projection is as follows (fig. 1): Describe a circle, NESW, to represent a meridian, and draw two diameters, NCS and WCE, perpendicular to each other, the one for a central meridian, the other for the equator. Then N and S will represent the north and south poles. Divide each of the quadrants into nine equal parts, and each of the radii, CN, CE, CS, and CW, also into nine equal parts. Produce NS both ways, and find on it the centres of circles which will pass through the three points 80° , 80° , 70° , 70° , &c., and these arcs described on both sides of the equator will be the parallels of latitude. In like manner, find on WE produced the centres of circles which must pass through *a*, *b*, &c., and the poles. Having selected the first meridian, number the others successively to the east and west of it. A map may in this way be constructed on the rational horizon of any place.

The impossibility of getting a satisfactory representation of special parts of the sphere by any of the previous methods leads to the desire for others less defective. Of all solid bodies whose surfaces can be accurately developed or rolled out upon a plane without alteration, the cone and cylinder approach nearest to the character of the sphere. A portion of the sphere between two parallels not far distant from each other corresponds very nearly to

a like conical zone; whence it is that conical developments make the best projections for limited portions of the earth's surface, and even with some modifications for more extensive portions.

A conical projection of Europe (fig. 2) is constructed thus: Draw a base-line, AB; bisect it in E, and at that point erect a perpendicular, ED, to form the central meridian of the map. Take a space for 5° of latitude, and, since Europe lies between the 35th and 75th parallels of latitude, mark off eight of these spaces along ED for the points through which the parallels must pass. The centre from which to describe the parallels will be the point in ED where the top of a cone, cutting the globe at the 45th and 65th parallels, would meet the axis of the sphere. This point will be found to be beyond the North Pole at C. On the parallels of 45° and 65°, where the cone cuts the sphere, mark off equivalents to 5° of longitude, in proportion to the degrees of latitude in those parallels, and if straight lines be drawn through these points from C they will represent the meridians for every 5°. A modification of the conic projection, suitable for more extensive portions of the sphere, such as Asia, is obtained by giving on each parallel of latitude the true meridional proportional distances, which results in a curving of the meridian lines outward from the centre of the map.

In all the projections hitherto described the direction either of the north and south, or of the east and west, is represented by a curved line, so

Fig. 2.—Conical Projection of Europe.

that on such a map the course of a vessel would almost always be laid down in a curve, which could only be described by continually laying off from the meridian a line at an angle equal to that made with the meridian by the point of the compass at which the ship was sailing. If the vessel were to steer in a direct north-east course by one of the previous projections, she would, if land did not intervene, describe a spiral. The mariner, however, requires a chart which will enable him to steer his course by compass in straight lines only. This valuable instrument is supplied by Mercator's chart, a cylindrical projection in which all the meridians are straight lines *perpendicular* to the equator, and all the parallels straight lines *parallel* to the equator. It is constructed thus (fig. 3): A line, AB, is drawn of the required length for the equator. This line is divided into 36, 24, or 18 equal parts, for meridians at 10°, 15°, or 20° apart, and the meridians are then drawn through these perpendicular to AB. From a table of meridional parts (a table of the number of times that the length of

a minute of longitude at the equator is to be comprised between that and every parallel of latitude up to 89°) take the distances of the parallels, tropics, and arctic and antarctic circles from the equator, and mark them off to north and south of it. Join these points, and the projection is made.

Fig. 3.—Mercator's Projection.

This projection, of course, does not give a natural representation of the earth, its effect being to exaggerate the polar regions immensely. The distortion in the form of countries and relative direction of places is rectified by the degrees of latitude being made to increase proportionably to those of longitude. There are other cylindrical projections of the sphere, but this is the most generally valuable and best known. It gives an unbroken view of the earth's surface with the exception of the poles, which are infinitely remote.

Historical.—The ancient Greeks considered Anaximander (560 B.C.) as the inventor of cartography; but there is evidence that about 1000 years earlier some attempts in that direction had been made amongst the Egyptians. Necessarily these efforts were of the crudest, and were made upon the supposition that the earth was a plane. After Aristotle the spherical theory was adopted, and the application of astronomical observations to geography was first made by Pytheas of Massilia (326 B.C.), and the first attempts at projections by Dicaearchus of Messana (310 B.C.). Ptolemy's (150 A.D.) rational teaching had an ultimate valuable influence in the treatment of cartography, although the Romans made little progress in the art, which during the middle ages also showed almost no advance. In the 14th and 15th centuries a gratifying improvement is observable in Italian nautical charts. In the 15th century the revivals of Ptolemy's teaching produced a revolution in the construction of maps, and laid the foundation of modern cartography. There was great increase in the number and importance of maps. The first attempts to improve and increase the methods of projection known to the Greeks were made by Germans, viz. Johann Stöffer (1452–1536), and Peter Apianus (1495–1552), &c. In the same period that Mercator (Gerhard Kremer, 1512–1594) made his invaluable contributions, the Italians, Germans, and Dutch were active competitors in geographical work. Amongst the increasing host of names connected with the subject are found that of Sebastian Cabot (1544), who produced his map of the world; in Germany, of Johann Baptist Homann (1644–1724) and Tobias Mayer (1723–86); in France, Nicolas Sanson (1600–67), Guillaume de l'Isle (1675–1726), and Jean Baptiste Bouguignon

d'Anville (1697-1782); and in Italy, P. Vincent Cornelli (d. 1718). In the 18th century France led the way in cartography by state survey result-

ing in the *Carte Géométrique de la France*. The British Ordnance Survey was begun in 1784. See CONTOUR LINES, DEGREE, EARTH, GEOLOGICAL

Map of British Islands, reduced from the Latin Ptolemy of 1478.

SURVEY, LATITUDE AND LONGITUDE, MERIDIAN, ORDNANCE SURVEY, SURVEYING.

Map (less correctly, **MAPES**), **WALTER**, a great 12th-century writer, was born on the Welsh marches, perhaps in Herefordshire, about 1137. He studied at the university of Paris, became an intimate friend of Becket, was a justice-in-eyre at Gloucester assize in 1173, attended the king the same year to Limoges, and for many years later, probably as chaplain, and was sent on missions to Paris and to Rome. He was parson of Westbury-on-Severn in Gloucestershire, where he had a long feud for his rights with the Cistercian monks of the neighbouring Flaxley Abbey, and became canon of St Paul's and precentor of Lincoln, but still continued his attendance on the king. In 1197, under Richard I, he became archdeacon of Oxford, and died before 1210. Map, who was perhaps Welsh, was a frank, open-hearted man, with a quick wit, bold humour, and an indignant contempt for hypocrisy. All these qualities are revealed in a number of Latin satirical poems long connected with his name. Criticism has assailed but not yet disproved the attribution. Of these the chief are the *Goliass* series (*Apocalypsis Goliæ*, *Predicatio*, *Confessio*, &c.). In the last named occurs the famous 'Meum est propositum in taberna mori.' In Bishop Goliass the writer has realised by creative imagination a type of the ribald priest, and upon his head he pours out the vials of his wrath and scorn, with humour rich, bold, sometimes coarse, but always honest. Map, if he was the author, seems to have kept the secret well, for even his friend Giraldus Cambrensis did not know their origin, as we find him, with the churchman's proverbial dislike to see the humorist point out the stains upon his cloth, denouncing Goliass as a foul-mouthed scoffer.

In any case, however, Map was not the first Goliardic writer. See **GOLIARDS**.

Sir Galahad, the stainless knight, may have been Map's creation, and there is reason, with M. Paulin Paris, to count him the heart and soul of that contemporary work of Christian spiritualisation which systematised and gave a meaning to the detached Arthurian romances. He wrote most probably the original of Robert de Borron's introductory romance of the *Saint Graal*, and of Ulrich von Zatzikhoven's *Lanzelet*. Manuscripts persistently attribute to him the great French prose *Lancelot*, including the *Lancelot proper*, the *Quest of the Saint Graal*, and the *Mort Artus*.

Undoubtedly Map's is a work of another kind, the *De Nugis Curialium*, a vivacious and entertaining miscellany or note-book of the court-gossip and events of the day, interspersed with theological polemics, anecdotes, and accounts of miracles, fairy legends, or *apparitiones fantasticæ*.

Thomas Wright edited for the Camden Society the *Latin Poems* (1841) and the *De Nugis Curialium* (1850). The latter has been edited by Dr M. R. James (1914), and translated by Tupper and Ogle (1924). See the *Cambridge History of English Literature* (vol. i. 1908), and James Hinton's study of the *De Nugibus* (1917).

Maple (*Acer*), the typical and the principal genus of the natural order *Aceraceæ*. The species are numerous, all are deciduous trees, and natives of the temperate parts of the northern hemisphere, and particularly numerous in North America and the north of India. They have opposite leaves without stipules, usually lobed or palmate. The flowers are in axillary corymbs or racemes of no beauty, but abound in honey, and are very attractive to bees. The fruit is formed of two small winged nuts, each with one or two seeds.—The

Common Maple (*A. campestre*), a small tree, is a native of Britain, and of many parts of Europe and Asia. The wood is compact, fine grained, and takes a high polish; hence it is much used by turners and for carved work, being frequently substituted for the wood of the Holly and Box by mathematical instrument makers. Several nearly-allied species are found in the south of Europe.—The Striped Bark Maple (*A. striatum*) of North

Fig. 1.—a, Common Maple (*Acer campestre*);
b, Japan Maple (*Acer palmatum*).

America, where it often forms great part of the undergrowth in woods, is so named because the smooth bark of the two-year-old branches are beautifully varied with green and white stripes; its wood, which is very white, is used for inlaying in cabinet-work.—The Greater Maple (*A. Pseudo-Platanus*), commonly called *Plane-tree* in Scotland, and *Sycamore* in England, is a native of Europe, but a doubtful native of Britain, in which, however, it has long been common. It attains a height of 70 to 90 feet, has a spreading umbrageous head, and large, palmate, coarsely serrated leaves on long stalks. It is of quick growth, and succeeds well near the sea and in

Fig. 2.—Greater Maple (*Acer Pseudo-Platanus*):
a, fruit.

other exposed situations. The wood is white, compact, and firm, though not hard; it is capable of a fine polish, and is used by wheelwrights, turners, &c. It is not apt to warp. Stair-rails are often made of it, and pattern-blocks for manufactories, as well as bowls, bread-plates, &c. Sugar is sometimes made from the sap of this tree, as from that of several other maples; but the species

which yields it most abundantly is the Sugar Maple (*A. saccharinum*) of North America, a species which much resembles it and abounds in the northern parts of the United States and in Canada, where large quantities of sugar are made from it. To obtain the sap the trees are tapped in February, March, and April, according to the locality and the season, and when warm days and frosty nights occur, which favour its flow. The boiling and refining processes are the same as those in the manufacture of cane-sugar. A single tree yields from two to six pounds in a season. Good vinegar is made from it, and a kind of molasses much superior to that from the sugar-cane, and much used in America with buckwheat cakes, &c. The wood of the Sugar Maple has a satiny appearance, and is used for cabinet-making; it is sometimes finely marked with undulations of fibre, and is then known as *Bird's-eye Maple*, and is used for veneers. The Sugar Maple is not so hardy in the climate of Britain as the Greater Maple, and seems to require a dry and sheltered situation.—The Norway Maple (*A. platanoides*), a native of the north of Europe, although not of Britain, is also found in North America; it much resembles the Great Maple.—A Himalayan species (*A. villosum*), a noble tree, found with pines and birches at great elevations, is sometimes grown in Britain. A large number of interesting and remarkably beautiful forms of several Japan species of *Acer*, such as *A. palmatum*, have been introduced; they have proved hardy in many favoured districts of England and Ireland, but are unsuited to Scotland generally, though they are occasionally seen there in conservatories cultivated in pots. In China and Formosa many new species have been discovered. A dye called Shinnamu is got from a Korean maple.

Maqui (*Aristotelia Macqui*), a plant of the family Elæocarpaceæ (by some united with Tiliaceæ), is an evergreen or sub-evergreen shrub, of considerable size, a native of Chile. The Chileans make a wine from its berry, which they administer in malignant fevers. The Maqui sometimes ripens fruit against a wall in England, and is frequently cultivated as an ornamental shrub. *A. racemosa* (native currant) and *A. fruticosa* (mountain currant) are New Zealand plants of the same genus.

Mar, a district of Scotland between the Dee and the Don, comprising nearly the south half of Aberdeenshire, and subdivided into Braemar, Midmar, and Cromar. In 1014 a Mormaer of Mar was present at the battle of Clontarf; and in 1115 another figures in the foundation charter of Scone priory as 'comes' or earl. The male line of these Celtic Earls of Mar expired in 1377 with Thomas, thirteenth earl, whose sister Margaret married William, first Earl of Douglas. Their daughter, Isabella, in 1404 married Alexander Stewart, the 'Wolf of Badenoch,' who, after her death in 1419, was designated Earl of Mar. The earldom was in 1565 restored, or granted by a new creation, to John, sixth Lord Erskine, who at his death in 1572 had been for a twelvemonth regent of Scotland. John, Earl of Mar (1675-1732), who began life as a Whig, and by his frequent change of sides earned the nickname of 'Bobbing Joan,' headed the rebellion of 1715 (see JACOBITES), and died in exile at Aachen. In 1824 the reversal of his attainder was procured by his grandson, John Francis Erskine, but his grandson dying without issue in 1866, the question arose whether the earldom of Mar could pass through his sister to her son, John Francis Goodeve-Erskine (né Goodeve), or must go to his first cousin, Walter Coningsby Erskine, Earl of Kellie. And the strange solution of that question has been that in 1875 Walter Henry Erskine, thirteenth Earl of Kellie,

was declared by the Committee of Privileges also eleventh Earl of Mar, and that in 1885 the Earl of Mar Restitution Bill declared Mr Goodeve-Edskine twenty-sixth Earl of Mar, claiming creation before 1014, but allowed precedence 1404. See the Earl of Crawford's *Earldom of Mar in Sunshine and Shade* (2 vols. Edin. 1882).

Marabou (*Leptoptilus crumenifer*), an African species of Adjutant (q.v.).

Marabouts, religious devotees or ascetics found chiefly in north Africa, who have at times exercised considerable political influence, as in encouraging opposition to the French conquests in Algeria and Tunis in the 19th century, and in former centuries as the origin and mainstay of the Almoravid dynasty, which held Morocco and Spain for a long period. These devotees are held in great veneration by the Berbers; they frequently officiate at mosques and chapels, and are believed to possess the power to prophesy and work miracles. The dignity is generally hereditary. The name is also applied to the tombs of the devotees.

Maracaibo, a city of Venezuela, is situated on the west shore of the strait which connects the lake and gulf of Maracaibo. It is a handsome town, with many gardens and squares, a college, hospitals, a theatre, a German club-house, the usual government buildings, a custom-house, wharves, and a number of manufactories. The climate is hot, the soil sandy, and the place unhealthy, owing mainly to the unsanitary domestic arrangements. The trade is chiefly in the hands of Germans, Danes, and North Americans. The staple export is coffee. Others are petrol, sugar, quina bark, woods. Pop. 35,000. Zulia state, of which it is capital, produces petroleum. Pop. about 120,000.

The *Gulf of Maracaibo* is a wide inlet of the Caribbean Sea, extending from the peninsulas of Paragana and Guajira to the strait by which it is connected with the lake. The latter forms the floor of a great valley, shut in by lofty mountains. Its waters are sweet, and deep enough for the largest vessels; but bars at the mouth, where a swift current runs, make entrance difficult. The gulf and lake were discovered in 1499 by Ojeda, who found houses built on piles, and so gave the district the name Venezuela ('Little Venice'), afterwards extended to the entire country.

Maragall, JUAN (1860–1912), Catalan lyric poet.

Maragha, a town of western Persia, 55 miles S. of Tabriz and 20 miles E. of Lake Urmia. It is celebrated as the capital of Hulagu Khan, grandson of Genghis Khan, and as the site of the observatory which Hulagu built for the astronomer Nasr ed-Din. Pop. 15,000.

Marajó, an island situated between the estuaries of the Amazon and Para, with an area of nearly 18,000 sq. m. It is for the most part low and covered with grass and bush, but in the east and south with dense forest. The soil is fertile, and large herds of cattle are reared in the north-east.

Maramuresh, a territory of 6258 sq. m. in the NW. of Rumania, acquired in 1919, being the southern part of the old Hungarian county of Máramaros (Marmaros); pop. (1920) 766,666. Chief town Sigheul Marmatsei (Máramaros-Sziget). The northern part went to Carpathian Ruthenia.

Maranhão, or MARANHÃO, a maritime state of Brazil, bounded on the north by the Atlantic Ocean, with an area of 177,566 sq. m. and a population of 874,000. The surface is uneven, but there is no range of mountains. There are numerous rivers, large forests, extensive plains where cattle are reared; the climate is fine, the soil fertile. Agriculture, however, has not prospered. Cotton

and sugar are the principal products.—The chief city is *Maranhão*, or *São Luiz de Maranhão*, on an island between the mouths of the Mearim and the Itapicuru. It is a well-built town, clean, gay, hospitable, and has a pop. of 53,000. It contains a cathedral and bishop's palace, a hospital, a technical school, cotton and sugar factories, and docks.

Marañón. See AMAZON.

Marantaceæ, an order of tropical (chiefly American) monocotyledons nearly allied to Zingiberaceæ and Cannaceæ. The unsymmetrical flowers, which grow in pairs (each a mirror-image of the other), have three sepals, three petals, one fertile stamen, a number of petaloid staminodes. The rhizome of *Maranta arundinacea* yields West Indian arrowroot.

Maraschí'no. See LIQUEUR.

Marash, a town of Turkey, 80 miles NE. of Alexandretta, is a market for Kurd carpets and embroideries. Hittite antiquities have been found. Pop. 50,000.

Marat, JEAN PAUL, French Revolutionary, was born at Boudry in Neuchâtel, 24th May 1743, eldest child of Jean Paul Mara, a native of Cagliari, who had married Louise Cabrol, a Genevan Protestant. He studied medicine at Bordeaux, next went to Paris, to Holland, and to London, where for some time he practised his profession with success, and published a materialistic *Philosophical Essay on Man* (1773), sharply attacking Helvétius, and anonymously a political essay, *The Chains of Slavery* (1774). In 1775 he paid a visit to Edinburgh, and was made on 30th June, on the recommendation of certain Edinburgh physicians, M.D. of St Andrews University. In June 1777 he was made brevet-physician to his guards by the Comte d'Artois, afterwards King Charles X.—an office which he held till 1786. Meantime he continued his scientific work in optics and electricity, attracting the attention of Franklin and Goethe, but the Académie des Sciences refused him admission on account of his attack on Newton. Further writings were his anonymous *Plan de Législation Criminelle* (1780), a translation of Newton's *Optics* (1787), and *Mémoires Académiques, ou Nouvelles Découvertes sur la Lumière* (1788).

But all Paris was now infected with the fever of revolution, and Marat flung himself with characteristic ardour into the war of pamphlets, and at length in September 1788 established his famous paper, *L'Ami du Peuple*. Throughout he fought ever for his own hand, with blear-eyed honesty and indomitable persistence, constantly croaking of treachery in high places, and denouncing with feverish suspiciousness in turn Necker, Bailly, Lafayette, the king, Dumouriez, and the Girondins. His virulence provoked the most vehement hatred, and covered his own head with calumnies which survived for generations; but it placed great power in his hands at some of the most momentous crises of the Revolution. His printing-press had to be cunningly concealed from Lafayette's police, twice at least he had to flee to London, and once he was forced to hide for a time in the sewers of Paris, where he contracted a loathsome skin disease, yet was tended with affectionate faithfulness by Simonne Evrard, whom he had married 'one fine day in presence of the sun.' His sufferings deepened his frienried hatred and suspicion of constituted authority, and there can be no doubt that on his head rests in great measure the guilt of the infamous September massacres. He was elected to the Convention as one of the deputies for Paris, and was perhaps the most unpopular man within the house, where indeed his influence never became more than contemptible. On the

declaration of the republic he started his paper anew under the title *Journal de la République Française*. After the king's death his last energies were spent in a mortal struggle with the Girondins, who subscribed their own downfall when their formal accusation of Marat failed before the tribunal. But it was the tribune's last triumph. He was dying fast of the disease he had contracted in the sewers, and could only write sitting in his bath. There his destiny reached him through the knife of Charlotte Corday (q.v.), in the evening of the 13th July 1793. His body was committed to the Panthéon with the greatest public honours, to be cast out but fifteen months later amid popular execration.

See the various histories of the French Revolution; Bougeart, *Marat l'Ami du Peuple* (2 vols. 1864); Bax, *Marat, the People's Friend* (1900); Phipson, *Marat: his Career in England and France before the Revolution* (1924); but especially the works by F. Chèvremont: *Marat, Index du Bibliophile* (1876), *Placards de Marat* (1877), and *Marat, esprit politique, accompagné de sa vie scientifique, politique, et privée* (2 vols. 1881).

Marathi. See MAHRATTAS, INDIA.

Marathon, a village on the east coast of ancient Attica, 22 miles NE. of Athens, long supposed to be the modern *Marathon*. It stood in a plain 6 miles long and from 3 to 1½ miles broad, with a background of mountains in the west, and a marsh both on the north and south; eastward it reached the sea.—The mountains look on Marathon, and Marathon looks on the sea. Recent investigations by Prussian officers identify the historic village with that of Brana, nearly 2½ miles to the south, and locate the battle in the plain between the mountain Stavrokoraki and the sea, nearly 3 miles north-east of Brana. The name of Marathon is gloriously memorable as the scene of the great defeat of the Persian hordes of Darius by the Greeks under Miltiades (490 B.C.)—one of the decisive battles of the world.

Marattiaceae, a primitive family of large tropical ferns of the Eusporangiate division, including Marattia, Angiopteris, and other genera. See FERNS.

Marave'di, an old Spanish copper coin in use from 1474 to 1848, was worth about ⅓rd of a penny. There were also, at an earlier period, maravedis of gold and of silver.

Marbeck, or MERBECKE, JOHN, organist of St George's Chapel, Windsor, was condemned to the stake in 1544 for favouring the Reformation, but pardoned for favour of Bishop Gardiner. In 1550 he published his famous *Boke of Common Praier Noted*, an adaptation of the plain-chant of the earlier rituals to the first liturgy of Edward VI. He wrote several theological and controversial works; and a hymn for three voices and parts of a mass by him are extant. He died about 1585.

Marble, in its strict and proper sense, is a rock crystallised in a saccharoidal manner, having the fracture of loaf-sugar, and composed of carbonate of lime, either almost pure when the colour is white, or combined with oxide of iron or other impurities which give various colours to it. But many other kinds of stone are popularly included under this title. Indeed any limestone rock sufficiently compact to admit of a polish is called marble. It is only in this vague sense that the indurated amorphous rocks used in Britain can receive this name. Such are the black, red, gray, and variegated limestones of the Devonian system, which are very beautiful from the numbers of exquisitely-preserved corals which abound in them; the marbles of the Carboniferous series from Flintshire, Derbyshire, and Yorkshire, so full of encrinites; the shell marbles from the Oolitic rocks at Rance, Stam-

ford, and Yeovil; and the dark Purbeck and Pétworth marbles, beautifully 'figured' with shells, from the Wealden strata, which were so much used by the architects of the middle ages.

Saccharine or statuary marble is a white fine-grained rock, resembling loaf-sugar in colour and texture, working freely in every direction, not liable to splinter, and taking a fine polish. Of the marbles used by the ancients, the most famous was Parian marble, a finely granular and very durable stone, with a waxy appearance when polished. Some of the finest Greek sculptures were formed of this marble, among others, the famous Venus de' Medici. The marble of Pentelicus was at one time preferred by the Greeks to Parian, because it was whiter and finer grained. The Parthenon was entirely built of it, and many famous statues still remain which were executed in this marble, but they are always more or less weathered, never retaining the beautiful finish of the Parian statues. The quarries at Carrara (q.v.) were known to the ancients, but they have been more extensively wrought for modern sculptors, who use this marble chiefly. It is a fine-grained, pure white marble, but is so often traversed by gray veins that it is difficult to get large blocks free from these. Of coloured marbles, the best known are the Rosso Antico, a deep blood-red, sprinkled with minute white dots; Verde Antico, a clouded green produced by a mixture of white marble and green serpentine; Giallo Antico, a deep yellow, with black or yellow rings; and Nero Antico, a deep black marble.

A true marble is a crystalline granular aggregate of calcite, the granules being of remarkably uniform size. Not infrequently scales of mica or talc occur scattered through the rock. Such a rock is of metamorphic origin: it is simply a limestone which has been rendered entirely crystalline from the effects of heat under pressure, as in the vicinity of large intrusions of igneous rock. Marble may therefore be of any geological age. Many crystalline limestones, which are sometimes entitled to the name of marble, occur associated with gneiss and mica-schist, and are often rich in such minerals as garnet, actinolite, zoisite, mica, &c.

Marburg, (1) a quaint old town in the Prussian province of Hesse-Nassau, on the Lahn, 59 miles by rail N. of Frankfurt and 64 SW. of Cassel. It is built on a terraced hill, whose summit is crowned by a stately castle, dating from 1065. In its Rittersaal (1277-1312) was held in 1529 the conference between the Wittenberg and the Swiss reformers regarding the Lord's Supper. The fine Gothic church of Elizabeth, with two towers 243 feet high, was built in 1235-83 by the Teutonic Knights over the splendid shrine of St Elizabeth (q.v.), and was thoroughly restored in 1850-67. The university occupies Gothic buildings of 1879. It was founded in 1527 in the Reformed interest by Philip the Magnanimous, Landgrave of Hesse; and among its earliest students were Patrick Hamilton and William Tyndale. Pop. 23,000.—(2) A town of Styria (Slovenian name *Maribor*) on the Drave, 30 miles NE. of Graz, assigned in 1919, notwithstanding its German population, to Yugoslavia; pop. 30,000.

Marcantonio, or, in full, MARCANTONIO RAIMONDI, engraver, born at Bologna late in the 15th century. A goldsmith by trade, he early turned to engraving, and received his first great stimulus from woodcuts of Albrecht Dürer, which he saw at Venice about 1505. He copied on copper two sets of plates from the German master's designs for the 'Life of the Virgin' and the 'Passion of Christ' (see DÜRER). At Rome, where he worked from 1510, he was chiefly engaged in engraving

Raphael's works, as 'Lucretia,' the 'Massacre of the Innocents,' the 'Three Doctors of the Church,' 'Adam and Eve,' 'Dido,' 'Poetry,' the 'Judgment of Paris,' &c., and subsequently those of Raphael's pupil, Giulio Romano. On account of the power of his drawing and the purity of his expression he is accounted the best amongst the engravers of the great painter. The capture of Rome by the Constable Bourbon in 1527 drove Marcantonio back to Bologna, where he probably remained until he died, some time before 1534 came to an end. See the essay by Fisher prefixed to the catalogue of his engraved works exhibited in London in 1868, and Delaborde's monograph (Paris, 1887).

Marcasite, an iron ore, a variety of Pyrites (q.v.).

Marceau, FRANÇOIS SÉVERIN DESGRAVIERS, French general, was born at Chartres on 1st March 1769. On the outbreak of the Revolution he was appointed inspector of the national guard in his native town, and in 1792 helped to defend Verdun with a body of volunteers till its surrender. His brilliant military career was ended in four years from this time; but they were four years of stirring activity. Sent in the following year to join the republican army in La Vendée, he was, for his services in the engagements before Saumur and Le Mans, promoted to the rank of general of division. Then, proceeding to the north-east frontier, he commanded the right wing at Fleurus, and after the allies retreated occupied Coblenz. During the campaign of 1796 he was given command of the first division of Jourdan's army, and sat down to invest Mainz, Mannheim, and Coblenz. But whilst covering the retreat of the French at Altenkirchen he was shot, on 19th September, and died of his wound. His body was buried in the entrenched camp at Coblenz but was transferred to the Panthéon in Paris in 1889. He ranks next after Hoche amongst the French generals of the early years of the Revolution, not only for military genius, but also on account of the nobility and uprightness of his personal character. See Lives by Doublet de Boisthibault (1851), Maze (1888), and Captain T. G. Johnson (1896).

Marcello, BENEDETTO, musical composer, born in Venice on 1st August 1686, was a judge of the republic, and a member of the Council of Forty, and afterwards held important administrative offices at Pola and Brescia, where he died on 24th July 1739. He had a passion for music, and is remembered as the composer of music for Giustiniani's version of the Psalms (8 vols. 1724-27), of numerous concertos, canzoni, cantatas, a pastoral, an oratorio, and other pieces, distinguished for their simple yet elevated style, and as the author of a satirical work, *Il Teatro alla Moda* (1720).

Marcellus, the name of two popes, of whom the second deserves special notice, as having, when Cardinal Marcello Cervini, taken a very prominent part in the discussions of the Council of Trent, over which he was appointed to preside as legate of Julius III. He was elected pope 10th April 1555, and survived his elevation but twenty-two days. He did not follow the usual custom of laying aside his baptismal name and assuming a new one.

Marcellus, M. CLAUDIUS, a famous Roman general, of one of the most eminent plebeian families. In his first consulship (222 B.C.) he defeated the Insubrian Gauls, and slew with his own hand their king, Britomartus or Viridomarus, whose spoils he dedicated as *spolia opima* to Jupiter—the third and last occasion in Roman history. In the second Punic war Marcellus took command

after the disaster of Cannæ, and put a check upon the victorious Hannibal at Nola, in Campania (216 B.C.). Again consul in 214 B.C., he gave a fresh impulse to the war in Sicily, but all his efforts to take Syracuse were rendered unavailing by the skill of Archimedes, and he was compelled regularly to blockade the city. Famine, pestilence, and ultimately treachery on the part of the Spanish auxiliaries of the Syracusans, opened its gates (212 B.C.), after which the remainder of Sicily was soon brought under the dominion of the Romans. In his fifth consulship, 208 B.C., he fell in a skirmish against Hannibal.

Marcet, JANE, known as MRS MARCET (1769-1858), was author of a very popular elementary introduction to chemistry entitled *Conversations on Chemistry*, through which Faraday made his first acquaintance with the subject, and of similar books on other branches of science, besides numerous charming *Stories for very Little Children*, in the estimation of many her best work. She was the daughter of a rich London merchant, a Swiss by birth, and was herself born at Geneva. She married Alexander Marcet, a Genevan. See Harriet Martineau's *Biographical Sketches* (1869).

March (Czech *Morava*), the principal river of Moravia, rises on the boundary between that region and Prussian Silesia, and flows 214 miles south to the Danube, which it joins 6 miles above Presburg. It receives on the right the Thaya. In its lower course it forms the boundary between Austria and Czechoslovakia. It is navigable for small boats from Göding, 50 miles from its mouth.

March, an urban district of Cambridgeshire, on the Nen, 14 miles E. of Peterborough and 16 NW. of Ely. Its church has a fine Perpendicular clere-story, with splendid roof. Pop. 9000.

March, the first month of the Roman year, and the third according to our present calendar. In England until 1752 the legal year was reckoned from the 25th March. Scotland had already made the change. Its last three days (old style) were once popularly supposed to have been *borrowed* by March from April, and are proverbially stormy.

March, a musical composition, chiefly for military bands, with wind-instruments and drums, intended to accompany the marching of troops. Marches are also introduced into operas, oratorios, symphonies, sonatas, &c. A march is usually but not always in common time, and like a minuet or a scherzo may have a so-called trio.

Marchantia. See LIVERWORTS.

Marchena, a town of Spain, 47 miles by rail E. by S. of Seville, with a ducal (Arcos) palace and sulphur-baths; pop. 15,000.

Marches, the border districts that run contiguous on each side of the boundary line between England and Scotland, and between England and Wales. The Lords of the Marches were the nobles to whom estates on the borders were given, on condition that they defended the country against the aggressions of the people on the other side. Under the Norman and Plantagenet kings of England there was almost chronic war between the English Lords of the Marches and the Welsh. For the Scottish-English Marches, see BORDERS.—The Mortimers, Earls of March, took their title from the Marches of Wales. In Scotland Dunbars and Lennoxes have been Earls of March, as have also Douglasses.—The corresponding German word *Mark* was in like manner applied to the border countries or districts of the German empire, conquered from neighbouring nations—the marks of Austria, of Brandenburg, Altmark, Steiermark, &c. The governor entrusted with the charge of a mark was called Markgraf (see MARQUIS).

The ancient German tribe of *Marcomanni* were 'Marchmen.' In Italy *The Marches* include the March of Ancona (q.v.) and three other provinces (see ITALY).—*Riding the Marches* is a procession on horseback along the boundary of a municipality (see BOUND).

Marcchetti, FILIPPO, an operatic composer, born at Bolognola in 1831, became in 1881 president of a musical college in Rome. His best-known operas are *Romeo e Giulietta* (1865) and *Ruy Blas* (1869). He died at Rome in 1902.

Marcianise, an agricultural town of Italy, situated in a marshy district, 18 miles by rail N. of Naples; pop. 15,000.

Marcion, the founder of the Marcionites, a rigorously ascetic sect which attained a great importance between the years 150 and 250 A.D. He was born at Sinope in Pontus about 100, became wealthy as a shipowner, and about 140 repaired to Rome. There he laboured to correct the prevailing views of Christianity, which he considered to be a corruption of Jewish errors with the gospel of Christ as expounded by Paul, its best interpreter. The opposition which he encountered drove him to found a new community about 144, and he laboured earnestly propagating his theology until his death about 165. Marcion was hardly a Gnostic, although he had been intimate with Cerdo, and Gnostic speculations certainly influenced the development of the Marcionite theology. Failing to recognise the New Testament God of love in the Old Testament, and profoundly influenced by the radical Pauline antithesis of law and gospel, he constructed an ethico-dualistic philosophy of religion, and proceeded to cosmological speculations which are not free from contradictions. He set aside as spurious all the gospels save Luke, and it, as well as the Pauline epistles, he purged of Judaizing interpolations. He was thus the earliest to make a canonical collection of New Testament writings. From the 4th century the Marcionites began to be absorbed in the Manichæans. See Gnosticism and works there quoted.

Marconi, GUGLIELMO, electrical engineer, was born at Bologna in 1874 (son of an Irishwoman), and educated at Leghorn. After much study of wireless telegraphy and many experiments he successfully communicated across the English Channel in 1899. His system, in use by Lloyd's and the principal shipping companies in England and abroad, was definitely adopted by the British Admiralty in 1900. In 1901 he succeeded in communicating across the Atlantic. In 1907 Marconi began a trans-Atlantic public service. In 1919 he was awarded a Nobel Prize for physics. See WIRELESS TELEGRAPH.

Marco Polo. See POLO.

Marcus Aurelius. See AURELIUS.

Mardi Gras. See SHROVETIDE.

Mardin, a town of Kurdistan, 60 miles SE. of Diarbekir; pop. 30,000.

Mare, WALTER DE LA. See DE LA MARE.

Maree, LOCH, a beautiful lake of Ross-shire, 40 miles W. of Dingwall. Lying 31 feet above sea-level, it is 1½ miles long, over 2 miles broad, 367 feet deep, and 11 sq. m. in area. It is overhung by mountains 3000 feet high; sends off the Ewe, 2 miles long, to the sea; and contains many islets.

Maremma (Lat. *Maritima*), a marshy region of Italy, extending along the sea-coast of Tuscany, and embracing an area of about 1000 sq. m. In Roman times and earlier the Maremma was a fruitful and populous plain; but the decay of

agriculture, consequent upon unsettled political history, fostered the encroachments of malaria. Leopold II. of Tuscany directed especial attention (1822-44) to the drainage and amelioration of the Maremma, and his efforts and subsequent measures have been attended with considerable success. Crops are now grown in the summer on the fertile soil of the infected area by the inhabitants of the adjoining hill-country, who go down only to sow and to reap their crops. During winter the Maremma is healthier and yields good pasture.

Marengo, a village of Northern Italy, in a marshy district near the Bormida, 3 miles SE. of Alessandria. Here on 14th June 1800 Napoleon, with 33,000 French, defeated 30,500 Austrians under Melas. It was the cavalry charge of the younger Kellermann that turned what looked like certain defeat into a decisive victory, though the French lost 7000 in killed and wounded, the Austrians only 6400 (besides 3000 prisoners).

Mareotis, or MAREIA, LAKE, the modern *El Mariût*, a salt lake or marsh in the north of Egypt, extends southward from Alexandria, and is separated from the Mediterranean, on its north-west side, by a narrow isthmus of sand. In the 15th and 16th centuries it was a navigable lake; in 1798 it was found by the French to be a dry sandy plain; but in 1801 the English army cut the dikes of the canal that separated the Lake of Aboukir from Mareotis, to cut off the water-supply of the French, and Mareotis became once more a marsh. The like happened in 1803, 1807, and 1882; but 'Mariût' has been partly drained again.

Mare's Tail (*Hippuris vulgaris*), a tall erect marsh-plant, with whorls of narrow leaves. See HALORAGACEÆ.

Margaret, St, Scottish queen, was born about 1045, probably in Hungary, daughter of the exiled Atheling Edward (son of Edmund Ironside), and of Agatha, said to be a kinswoman of Gisela, queen of St Stephen of Hungary, and sister of the Emperor Henry II. It is not certain when she came to England, or how long she had been there when in 1068, with her mother and sister (Christina) and her brother, Edgar the Atheling (q.v.), she fled from Norman England and was driven ashore at the place now called St Margaret's Hope. Young, lovely, learned, and pious, she won the heart of the rude Scottish king, Malcolm Canmore (q.v.), who wedded her at Dunfermline. 'Perhaps,' says Skene, 'there is no more beautiful character recorded in history than that of Margaret. For purity of motives, for an earnest desire to benefit the people among whom her lot was cast, for a deep sense of religion and great personal piety, for the unselfish performance of whatever duty lay before her, and for entire self-abnegation she is unsurpassed.' Other historians are less ecstatic. She did much to civilise the northern realm, and still more to assimilate the old Celtic church to the rest of Christendom on such points as the due commencement of Lent, the Easter communion, the observance of Sunday, and marriage within the prohibited degrees. She built, too, a stately church at Dunfermline, and re-founded Iona. She bore her husband six sons and two daughters, and died three days after him, in Edinburgh Castle, on 16th November 1093. Innocent IV. canonised her in 1250. Her head, which had found its way from Dunfermline to Douai, was lost in the French Revolution; but her remaining relics are said to have been enshrined by Philip II. in the Escorial.

See the Latin Life attributed to her confessor Turgot, Bishop of St Andrews, but perhaps by a less-known monk Theodoric (Eng. trans. by Fr. Forbes-Leith, 1884); English Lives by Cowan (1911), and Lucy Menzies (1925);

Skene's *Celtic Scotland* (vol. ii. 1877); Bellesheim's *History of the Catholic Church of Scotland* (trans. 1887).

Margaret, queen of Denmark, Norway, and Sweden, was the second daughter of Waldemar IV. of Denmark, and wife of Haakon VIII. of Norway, and was born in 1353. On the death of her father without male heirs in 1375, the Danish nobles offered her the crown in trust for her infant son Olaf. By the death of Haakon in 1380 Margaret became ruler of Norway as well as of Denmark. When Olaf died in 1387 Margaret nominated her grand-nephew, Eric of Pomerania, as her successor. The Swedish king, Albert of Mecklenburg, having so thoroughly alienated the affections of his subjects that the nobles, declaring the throne vacant, offered in 1388 to acknowledge Margaret as their ruler, she sent an army into Sweden, which defeated the king's German troops near Falköping, and took Albert and his son prisoners. Albert remained in prison seven years, during which time Margaret, in spite of the efforts of the Hanseatic League and its allies, wholly subjugated Sweden. In the following year (1396) Eric of Pomerania was crowned king of the three Scandinavian kingdoms, and though he was proclaimed king *de facto* next year, the power still remained in the hands of Margaret. In May 1397 was signed the celebrated Union of Kalmar, by which it was stipulated that the three kingdoms should remain for ever at peace under one king, though each should retain its own laws and customs. Before her death at Flensburg on 28th October 1412, Margaret had enlarged the territories she held for her grand-nephew by the acquisition of Lapland and part of Finland. She was a woman of masculine energy and strong will, and ruled her subjects with a firm hand. See a Life by M. Hill (1898).

Margaret of Anjou, the queen of Henry VI. of England, was daughter of René of Anjou, the titular king of Sicily, and of Isabella of Lorraine, and was born at Pont-à-Mousson, in Lorraine, 24th March 1429. She was married to Henry VI. of England in 1445; and her husband being a person whose naturally weak intellect was sometimes darkened by complete imbecility, she exercised an almost unlimited authority over him, and was the virtual sovereign of the realm. A secret contract at her marriage, by which Maine and Anjou were relinquished to the French, excited great dissatisfaction in England, and the war with the French which broke out anew in 1449, in the course of which all Normandy was lost, was laid by the English to the charge of the already unpopular queen. In 1450 occurred the insurrection of Jack Cade, and soon after the country was plunged in the horrors of that bloody civil war known as the Wars of the Roses. Margaret took an active part in the contest, braving disaster and defeat with the most heroic courage. At length, after a struggle of nearly twenty years, Margaret was finally defeated at Tewkesbury, and flung into the Tower, where she remained four years, till Louis XI. redeemed her for fifty thousand crowns. She then retired to France, and died at the château of Dampierre, near Saumur, in Anjou, 25th August 1492. Mrs Hookham's *Life* (1872) is not altogether satisfactory as history.

Margaret of Navarre, in her youth known as Marguerite d'Angoulême, sister of Francis I. of France, and daughter of Charles of Orleans, Comte d'Angoulême, was born at Angoulême, 11th April 1492. She was carefully educated, and early showed remarkable sweetness and charm added to unusual strength of mind. In 1509 she was married to Charles, Duke of Alençon, who died in 1525; and in 1527 she was married to Henri d'Albret, titular king of Navarre, to whom she

bore Jeanne d'Albret, mother of the great French monarch, Henry IV. She encouraged agriculture, the arts, and learning, and sheltered with a courageous generosity such advocates of freer thought in religion as Marot and Bonaventure des Périers. Accusations entirely unfounded have been brought by interested bigotry against her morals. She died 21st December 1549. Her writings include a series of remarkably interesting Letters (ed. by Génin, 2 vols. 1842-43), a miscellaneous collection of poems gracefully entitled *Les Marguerites de la Marguerite* (ed. by Frank, 4 vols. 1873), and especially the famous *Heptaméron des Nouvelles* (1558; ed. by Leroux de Lincy, 3 vols. 1855), modelled on the *Decameron* of Boccaccio, but worked out in an original manner. A company of ladies and gentlemen returning from Canterbury are detained by bad weather, and beguile the time by telling stories, seventy-two in number, which are separated by interludes introducing the persons. The subjects of the stories are similar to those of the *Decameron*, but the manners delineated are more refined; and they reflect closely the strange combination of religious fervour with religious free-thinking and refined voluptuousness so characteristic of the time. Most critics believe the work to be partly by Des Périers (q.v.). Her *Dernières Poésies*, discovered in the Bibliothèque Nationale in 1895, were published in 1896. See Lives by Durand (1848), Miss Freer (1854), and Lotheisen (Berlin, 1885); and Saintsbury's introduction to the new translation of the *Heptaméron* (1894).

Margaret of Scotland (1425?-45), an unfortunate and accomplished princess, daughter of James I. (q.v.) of Scotland, married in 1436 to the Dauphin, afterwards Louis XI. of France, who proved a heartless and callous husband. She sought solace for her husband's neglect in books and in poetry, spending sleepless nights in writing rondeaux. An impossible legend makes her the too kind patron of the famous poet, Alain Chartier (q.v.), who was of the commission that went to Scotland to solicit her hand, but was probably dead before her wedded troubles began. See Jusserand's *English Essays from a French Pen* (1895); Rait's *Five Stuart Princesses* (1902); and a book by Barbé (1917).

Margarine. See BUTTER, ADULTERATION. — MARGARIC ACID is a mixture of palmitic and stearic acids; see FATS.

Margarita, an island in the Caribbean Sea, belonging to Venezuela; area, 380 sq. m. Discovered by Columbus in 1498, Margarita has revived its pearl-fisheries, but now its chief export is salted fish.

Margary, AUGUSTUS RAYMOND (1846-75), the son of an English officer in India, was for six years in the diplomatic service in China. In August 1874 he was sent to meet a British mission seeking to open the overland route between Burma and China, and, as interpreter, was returning with the mission when in February 1875 he was murdered by the Chinese at Manwyne. See his *Journal*, edited by Sir R. Alcock (1876).

Margate, a seaport and municipal borough of England, in the Isle of Thanet, Kent, 3 miles W. of the North Foreland and 74 E. by S. of London, has for many years been the favourite seaside resort of cockney holiday-makers, who, during the season, by rail and by steamer, pour into the town in their thousands. Possessed of many natural advantages in its bracing air, good bathing, and excellent firm sands, Margate offers besides all the customary attractions of a watering-place, with its pier (900 feet long), jetty (upwards of a quarter of a mile in length), theatre, assembly-rooms, baths, zoological gardens, &c. It contains also two interesting

churches—one exhibiting traces of Norman and Early English work, and the other with a tower of 135 feet, forming a conspicuous landmark; the Royal Sea-bathing Infirmary, founded 1792 and enlarged 1882; a town-hall (1820); and an extensive deaf and dumb asylum (1875–80–86). Turner the painter (one of whose earliest known sketches is a view of Margate church) was at school in Margate for a short time. Pop. (1801) 4766; (1891) 18,419; (1911) 27,086; (1921) 46,475.

Margaux, a village near the Gironde, 15 miles NNW. of Bordeaux, is famous for its wines.

Margay (*Felis tigrina*), a species of cat or tiger-cat, a native of the forests of Brazil and Guiana, smaller and less handsome than the ocelot, which in general appearance it much resembles, though its spots are smaller. It is little larger than the domestic cat. It is capable of domestication, and of being made very useful in rat-killing.

Marghilan. See FERGHANA.

Marginal Credit, or more correctly **MARGINAL LETTER OF CREDIT**, is a letter issued usually by a banker and attached to or printed in the margin of a Bill of Exchange (q.v.) authorising the person to whom it is addressed to draw on the banker the annexed bill of exchange and undertaking to honour the bill if drawn in accordance with the terms of the letter. This service the banker undertakes for a client who is desirous of making payment abroad, but whose financial position is not sufficiently well known there to allow of bills drawn upon him being saleable, or saleable at the most favourable rate. His client having deposited cash or securities, the banker lends, as it were, the credit of his name, charging a commission for the risk involved.

Margrave. See MARCHES, MARQUIS.

Marguerite. See MARGARET.

Marguerite. See CHRYSANTHEMUM.

Marheineke, PHILIPP CONRAD (1780–1846), Protestant theologian, born at Hildesheim, was professor and university preacher at Erlangen in 1805, and subsequently held theological chairs at Heidelberg (from 1807) and Berlin (from 1811). After Hegel's death he was the chief figure among the right wing of that philosopher's disciples.

Mari, or **CHEREMISSES**, a Finnish people of the Volga basin. An autonomous Mari territory was set up in 1920; area, 7300 sq. m.; pop. 400,000; capital, Krasnokokshaik ('red Kokshaik'; formerly called Tsarevokokshaik; pop. 2000).

Maria Christina, queen of Spain, born at Naples, 27th April 1806, was a daughter of Francis I., king of the Two Sicilies. In 1829 she became the fourth wife of Ferdinand VII. of Spain, and in October of that year gave birth to a daughter, Isabella II. Ferdinand died 29th September 1833, and by his testament his widow was appointed guardian of her children—the young Queen Isabella and the Infanta Maria Louisa, Duchess de Montpensier—and also regent. A civil war broke out (see CARLISTS); but the queen-mother seemed indifferent to everything except the company of Don Fernando Muñoz, whom she made her chamberlain, and with whom she was united, in December 1833, in a morganatic marriage. She had ten children by him. A conspiracy, which broke out on the night of the 13th August 1836, led the queen-mother to concede a constitution to Spain. In 1840 a popular commotion ensued, and she gave to the new prime-minister, Espartero, a renunciation of the regency, and retired to France, whence she returned in 1843. Her participation in the

schemes of Louis-Philippe as to the marriage of her daughters in 1846, and the continual exercise of her influence in a manner unfavourable to constitutional liberty, made her hateful to the patriotic party in Spain. At length, in July 1854, a revolution expelled her from the country, and she again took refuge in France, but returned to Spain in 1864, only to retire again in 1868. She died at Le Havre, August 1878. See CARLISTS, and SPAIN.

Maria Louisa, the second wife of Napoleon I., born 12th December 1791, was the daughter of the Emperor Francis I. of Austria. She was married to Napoleon after the divorce of Josephine, 2d April 1810. On 20th March following she bore a son, who was called King of Rome. At the beginning of the campaign of 1813 Napoleon appointed her regent in his absence, but under many limitations. On the abdication of Napoleon, being advised not to follow him into exile, she went with her son to Schönbrunn, where she remained till 1816, when she received the duchies of Parma, Piacenza, and Guastalla. In 1822 she contracted a morganatic marriage with Count von Neipperg. She died at Parma, 17th December 1847.

See *Lives by Helfert* (1873) and *Imbert de Saint-Amand* (trans. 1886), her *Correspondance* (1887), the *Mémoires* of Mme Durand (1885), and Mrs Cuthell's (apologetic) *An Imperial Victim* (1911).

Mariana, JUAN, a Spanish historian, was born at Talavera in 1536, entered at eighteen the then rising order of the Jesuits, and afterwards taught in the Jesuit colleges at Rome (where Bellarmine was one of his scholars), in Sicily, and finally in Paris. After seven years of labour in Paris he was driven by ill-health to Toledo, and there he lived in unbroken literary labours till his death, at an extreme old age, in 1624. His *Historiæ de Rebus Hispaniæ* first appeared in 20 books in 1592, and was supplemented by 10 additional books, carrying the narrative down to the accession of Charles V., in 1605. Its admirable Latinity and undoubted historical merits give it an abiding value. Mariana himself published a Spanish translation (1601–9), which still remains one of the classics of the language. His *Tractatus VII. Theologici et Historici* (1609) roused the suspicion of the Inquisition. But the most celebrated of the works of Mariana is his well-known treatise *De Rege et Regis Institutione* (1599), which raises the question whether it be lawful to overthrow a tyrant, and answers it in the affirmative, even where the tyrant is not a usurper but a lawful king. This tyrannicide doctrine drew much odium upon the entire order of Jesuits, especially after the murder of Henry IV. of France by Ravaillac in 1610; but it is only just to observe that, while, upon the one hand, precisely the same doctrines were taught in almost the same words by several of the Protestant contemporaries of Mariana, on the other, Mariana's book itself was formally condemned by the general Acquaviva, and the doctrine forbidden to be taught by members of the order. See a study by Cirot (1905).

Mariana Islands. See LADRONES.

Marianus Scotus (1028–c. 1082), an Irish chronicler, who, quitting his country in 1052, became a Benedictine at Cologne in 1058, and settled in the monastery at Fulda. Ten years later he removed to Mainz, where he taught mathematics and theology. He left a *Chronicon Universale*, which began at the creation and came down to 1082. It was published at Basel in 1559, and by Waitz in 'Monumenta Germaniæ.'—Another **MARIANUS SCOTUS**, famous as a copyist and calligrapher, was abbot of St Peter's at Ratisbon in 1088.

Maria Stella (d. 1843), claimed to be a daughter of Philip of Orleans, for whom Louis-Philippe had been substituted at birth.

Maria Theresa, or **MARIA THERESIA**, empress, daughter of the Emperor Charles VI., was born at Vienna, 13th May 1717. By the Pragmatic Sanction (q.v.), her father appointed her heir to his hereditary thrones. In 1736 she married Francis of Lorraine, afterwards Grand-duke of Tuscany. On the death of her father, 21st October 1740, she became queen of Hungary and of Bohemia, and Archduchess of Austria. At her accession the monarchy was exhausted, the finances embarrassed, the people discontented, and the army weak; whilst Prussia, Bavaria, Saxony, and Sardinia, abetted by France, put forward claims to her dominions. Frederick II. of Prussia claimed Silesia, and poured his armies into it; Spain laid hands on the Austrian dominions in Italy; and the Bavarians, assisted by the French, invaded Bohemia, and, passing on into the archduchy of Austria, threatened Vienna, the Elector of Bavaria being crowned king of Bohemia and emperor as Charles VII. (1742). The young queen was saved by the Hungarians, with the assistance of Britain, but most of all by her own resolute spirit. The war of the Austrian Succession, after lasting more than seven years, was terminated by the peace of Aachen in 1748. The empress-queen lost the duchies of Parma, Piacenza, and Guastalla to Spain, and some Milanese districts to Sardinia, while her cession of Silesia and Glatz to Prussia, made in the treaty of Dresden (1745), was guaranteed. On the other hand, her titles were fully recognised, as well as that of her husband, who had been nominated emperor (1745), Charles of Bavaria having in the meantime died. During the years of peace that ensued Maria Theresa instituted important financial reforms, did her utmost to foster agriculture, manufactures, and commerce, and improved and nearly doubled the national revenues, whilst the burdens were diminished. At the same time she charged Marshal Daun to reorganise and rediscipline her armies. In Kaunitz (q.v.) she had a minister possessed of wisdom and energy, and in his hands she left for the most part the management of the foreign relations of the empire. But the loss of Silesia, especially the conduct of Frederick the Great, which had brought upon her that loss, rankled deeply in her mind; and, France having been gained as an ally through the address of Kaunitz, she renewed the contest with the Prussian king. But the issue of the Seven Years' War (q.v.) was to confirm Frederick in the possession of Silesia. On the conclusion of hostilities the empress renewed her efforts to promote the national prosperity, ameliorating the condition of the peasantry, mitigating the penal code, founding schools, organising great charitable societies, in short promoting the welfare of her subjects by all the wise arts of peaceful progress. Her son Joseph, elected king of the Romans in 1764, she associated, after the death of her husband (1765), with herself in the government of her hereditary states, but in reality committed to him the charge only of military affairs. She joined with Russia and Prussia in the first partition of Poland (1772), whereby Galicia and Lodomeria were added to her dominions. She also obtained from the Porte Bukowina (1777). On the death of the childless Elector of Bavaria Austria successfully asserted her claim to the 'quarter of the Inn' and one or two other districts. Maria Theresa died 29th November 1780. Personally a woman of majestic and winning appearance, she was animated by truly regal sentiments and an undaunted spirit; and by this rare union of feminine tact with masculine energy and restless activity, she not only won the affection and even enthusiastic admiration of her subjects, but she raised Austria from a most wretched con-

dition to a position of assured power. Her reign marks the transition of Austria from a medieval to a modern state; and by her efforts the beginning was successfully made of fusing into one sovereignty the heterogeneous lands ruled over by the House of Hapsburg. Although a zealous Roman Catholic, Maria Theresa maintained the rights of her own crown against the court of Rome, and endeavoured to correct some of the worst abuses in the church. Of her ten surviving children, the eldest son, Joseph II., succeeded her; Leopold, Grand-duke of Tuscany, followed his brother on the imperial throne as Leopold II.; Ferdinand became Duke of Modena; and Marie Antoinette was married to Louis XVI. of France. See *History* by Arneth (10 vols. 1863-79, an Austrian version); other works by Arneth, by Duller, Ramshorn, Wolf, and J. F. Bright (1897); the book on the Empress and Frederick by the Duc de Broglie (trans. 1883); Miss Moffat's *Life of her* (1911); and works quoted under **FREDERICK II.**

Mariazell, the most famous place of pilgrimage in Austria, in the extreme north of Styria, 25 miles N. of Bruck and 60 SW. of Vienna, amidst romantic scenery. It is visited by hundreds of thousands of pilgrims annually. The image of the Virgin (brought here in 1157), the object of the pilgrimages, is enshrined in a magnificent church, built in 1644 on the site of an older one. Four miles from the village are important ironworks. See the history by Eigner (1901).

Maribor. See **MARBURG**.

Marie Amélie, queen of Louis-Philippe (q.v.).

Marie Antoinette, **JOSEPHÉ JEANNE**, queen of France, was born at Vienna on the day of the great earthquake at Lisbon, 2d November 1755, the fourth daughter of Maria Theresa and the Emperor Francis I. From her cradle she was destined by her ambitious mother to be queen of France, and to that end was educated, although but indifferently, by the Abbé de Vermond. The marriage was negotiated by the Duc de Choiseul early in 1770, and took place on May 16, but was darkened a fortnight later by an ill-omened panic during the great fête of fireworks given in its honour by the city of Paris, in which some hundreds of people perished. The beautiful young dauphiness soon found her position full of difficulties, and the stiff and stately etiquette of the old French court wearied her to death. A mere child in years, married to a dull, decorous, and heavy husband, who was, moreover, for some years indifferent to her person, she found relief in a capricious recklessness of conduct and a disregard for conventions, and so from the first laid herself open to serious scandals for which there never was any real ground but her own indiscretion. Her night drives to Paris, her appearance at masked balls, her extravagance and undisguised love for the card-table, and her open favour to handsome and profligate young men, were misread into shameless immoralities, and she had lost her reputation long before she awoke to a sense of her responsibilities. In May 1774 the death of Louis XV. made her queen of France, and she soon deepened the dislike of her subjects by her undisguised devotion to the unpopular Franco-Austrian alliance, as well as by her reckless opposition to all the measures devised by Turgot and Necker for relieving the financial distress of the country. The miseries of France became in the popular imagination identified with the extravagant pleasures of the queen, and in the affair of the Diamond Necklace (q.v.) her guilt was at once taken for granted, and 'the Austrian' became the object of the frenzied hatred of a starving

people. The act of accusation against Calonne (q.v.) was in the eyes of the mob that of the court and of the queen. Showers of virulent pamphlets rained from all sides, and 'Madame Dédit' and 'Madame Veto' were some of the names in which a maddened people shrieked their hatred against the queen.

Meantime the frivolity of the girl had changed into the courage and obstinacy of the woman who made herself a centre of opposition to all new ideas, and prompted the poor vacillating king into a retrograde policy to his own undoing. She was capable of strength rising to the heroic—as Mirabeau once said, the only man the king had about him was his wife. And she possessed the power of inspiring enthusiasm, as is evidenced by the personal influence she exercised over Fersen, Mirabeau, and Barnave. Amid the horrors of the march of women to Versailles (October 5-6, 1789) she alone maintained her courage, and she showed herself on the balcony to the raging mob with a serene heroism that for a moment overawed the fiercest into respect. That same day the royal family and the Assembly left Versailles for Paris. But Marie Antoinette lacked consistency even in the part she essayed to play, and to the last she failed to understand the nature of the troublous times into which she had been flung. She had an instinctive abhorrence of the liberal nobles like Lafayette and Mirabeau, and, if she professed to consult them, she also consulted other men, and refused to trust them altogether. Again the indecision of Louis and his dread of civil war hampered her plans, and the intrigues of the Émigrés (q.v.) did her cause more harm than all her domestic enemies together.

The queen was at length prevailed on by Comte de Mercy-Argenteau, at the instigation of Comte de la Marck, to make terms with Mirabeau, and to him she gave an interview at Saint-Cloud, 3d July 1790. But she was too self-willed and independent frankly to follow his advice, for she abhorred his dream of a constitutional monarchy based on the free consent of an enfranchised people. His death in April 1791 removed the last hope of saving the monarchy, and less than three months later occurred the fatal flight to the Marquis de Bouillé at the frontier, intercepted at Varennes, against which Mirabeau had ever pleaded as a fatal step. The storming of the Tuileries and slaughter of the brave Swiss guards (10th August 1792), the transference to the Temple, the trial and execution of the king (21st January 1793), quickly followed, and ere long her son was torn from her arms, and she herself sent to the Conciergerie (2d August 1793). After eight weeks more of brutal confinement the 'Widow Capet' was herself arraigned before the Revolutionary Tribunal. Under the ordeal of her trial, even in the face of a charge of incestuous intercourse with her son of eight years old, brought against her by Hébert, she bore herself with calm dignity and resignation. After two days and nights of questioning she was found guilty of having lent counsel to the foreign enemies of France, and of having fomented civil war; that in the interests of the monarchy she had intrigued abroad against the existing government there can be no question, while from her very position she was at home necessarily an enemy of the republic. The inevitable sentence followed, and on the same day as its pronouncement, 16th October 1793, Marie Antoinette was guillotined.

There is a bibliographical study by Tournoux, *Marie Antoinette devant l'histoire* (Paris, 2d ed. 1901). See the *Histories of the French Revolution* by Thiers, Mignet, Michelet, Louis Blanc, Carlyle, Von Sybel, H. Morse Stephens *passim*, and, where much that has been written

is biased either for or against, a good estimate in vol. ii. (*passim*) of Sorel's *L'Europe et la Révolution Française* (1885-1911); see also Madame Campan's *Mémoires sur la Vie privée de Marie Antoinette* (1823); De Lescure's *La vraie Marie Antoinette* (1863); D'Hunolstein's *Correspondance inédite de Marie Antoinette* (1864); Feuilleton des Conches's *Louis XVI., Marie Antoinette, et Madame Élisabeth, Lettres et Documents inédits* (1865), a work which with the preceding contains many forgeries; Arneth and Geffroy, *Marie Antoinette: Correspondance secrète entre Marie-Thérèse et le Comte de Mercy-Argenteau* (1874); studies by De Nolhac (1890; trans. 1898) and De la Rocheterie (1890; trans. 1893); works by Anna Bicknell (1898), Clara Tschudi (1898), and C. N. Scott (1905); M. C. Bishop, *The Prison Life of Marie Antoinette* (1893); and for the affair of the Diamond Necklace, G. C. D'Est Ange's *Marie Antoinette et le Procès du Collier* (1889). For an account of her portraits, about 500 in number, see Lord Ronald Gower's *Iconographie de Marie Antoinette* (Paris, 1883); and for the closing scenes in her life, Campardon's *Tribunal Révolutionnaire* (vol. i.) and *Marie Antoinette à la Conciergerie* (1863), Lord Ronald Gower's *Last Days of Marie Antoinette* (1885), and L. de Saint-Amand, *Les dernières Années de Marie Antoinette* (1889; Eng. trans. 1891).

Marie de France, a poetess of whom but little is known with any degree of certainty, save that she lived in England under Henry III., and translated into French from an English version of a Latin translation of the Greek the *Ysopet*, a collection of 103 moralised fables, in octosyllabic couplets, 'for the love of Count William' (supposed to be William Longsword of Salisbury). These fables are natural and happy, as well as graceful in versification, and give their authoress a place in that line of descent which ended with La Fontaine. But her greatest work was the twelve (or fourteen) *Lais*, delightful and genuinely poetic narrative poems, mostly amatory in character, in octosyllabic verse, the longest nearly twelve hundred lines, the shortest just over a hundred. The word *Lai* is of Breton origin, and most probably referred originally to the style of music with which the harper accompanied his verse. The titles of Marie's *lais* are *Guigemar*, *Equitan*, *Le Fraisne*, *Bisclavret*, *Lanval*, *Les Dous Amanz*, *Yonec*, *Laustic*, *Milun*, *Chaitivel*, *Chievrefoil*, *Eliduc*; and to these most add *Graelent* and *L'Espine*. Of the *lais* the best edition is that of Karl Warnke (Halle, 1885; new ed. 1900), forming vol. iii. of Suchier's *Bibliotheca Normannica*, enriched with invaluable comparative notes by Reinhold Köhler. The fables, by the same editor, form the sixth volume (1898). The *lais* were paraphrased rather than translated by O'Shaughnessy as *Lays of France* (1872). A third work sometimes ascribed to Marie is a poem of 2300 verses on the purgatory of St Patrick.

Marie de' Medici, wife of Henry IV. of France, was the daughter of Francis I., Grand-duke of Tuscany, and was born at Florence, 26th April 1573. She was married to Henry, 16th December 1600, and in the following September gave birth to a son, afterwards Louis XIII. The union, however, did not prove happy. Marie was an obstinate and passionate woman, and her quarrels with the king soon became the talk of Paris. She was wholly under the influence of her favourites, Leonore Galigai and her husband Concini, and was by them encouraged in her dislike to her husband. The murder of Henry (May 14, 1610) did not greatly grieve her, although it is not true that she was privy to the plot. For the next seven years she governed as regent, but proved as worthless a ruler as she had been a wife. After the murder of Concini (24th April 1617), whom she had created Marquis d'Ancre, a domestic revolution took place, and the young Louis XIII. assumed royal power. The queen was confined to her own house, and her son refused to see her. Her par-

tisans tried to bring about a civil war, but their attempts proved futile; and by the advice of Richelieu, then Bishop of Luçon, she made her submission to her son in 1619, and took her place at Court. Marie hoped to win over Richelieu to her party, but she soon found out that he had no mind to be ruled by her, whereupon she tried to undermine his influence with the king. Her intrigues for this purpose failed; she was imprisoned in Compiègne, whence she escaped and fled to Brussels in 1631. Her last years were spent in utter destitution, and she is said to have died in a hayloft at Cologne, 3d July 1642. She loved the fine arts, and Paris owes to her the Luxembourg. See books by Zeller (1877-99), Miss Pardoe (new ed. 1902), and Batiffol (1906; Eng. trans. 1908).

Marie Galante, a French island, discovered by Columbus in 1493, 17 miles SE. of Guadeloupe. Area, 58 sq. m. It is mostly wooded, and surrounded by coral reefs. Sugar, coffee, cocoa, and cotton are exported. Pop. 20,000. Chief town, Grandbourg, or Marigot, on the south-west coast.

Mariénbad (Czech, *Marianské Lázně*), a Bohemian spa, 47 miles by rail NW. of Pilsen, 2057 feet above sea-level, is surrounded by wooded heights. The springs have long been used by the people of the neighbourhood, but it is only since 1807-8 that it has become a place of resort for persons from distant parts of the world. The springs are numerous, varying in temperature from 48° to 54° F. They are saline, containing sulphate of soda and various alkaline ingredients, but differing considerably in their composition and qualities. The waters are used both for drinking and for bathing. Great quantities are exported.

Marienburg, an old town of Prussia, on the Nogat, 30 miles by rail SSE. of Danzig. It was long the seat of the Grand Masters of the Teutonic Order (q.v.), who removed from Venice hither in 1309. The fortress of the Knights, however, was founded here about 1274. Marienburg remained in their hands till 1457, when it was taken by the Poles, and by them it was held till 1772. The castle, in which seventeen Grand Masters resided, a noble edifice in a style of Gothic peculiar to the neighbourhood of the Baltic, was thoroughly restored in 1817-42. Pop. 14,000.

Marienwerder, a town of Prussia, is picturesquely situated 3 miles E. of the Vistula and 55 by rail S. of Danzig. It was founded in 1233 by the Teutonic Knights, and has an old castle and a cathedral (1384). Pop. 13,000. In 1920 a region of West Prussia, including Marienwerder and Marienburg, decided by a 97 per cent. vote to be German rather than Polish.

Marietta, capital of Washington county, Ohio, on the Ohio River, 105 miles SE. of Columbus. Founded in 1788, it is the oldest town in the state, is the seat of Marietta College (1835), and has varied manufactures and a trade in the petroleum found near by. Remarkable traces of the mound-builders are visible here. Pop. 15,000.

Mariette Pasha, FRANÇOIS AUGUSTE FERDINAND, Egyptian explorer, was born at Boulogne, 11th February 1821, and was educated at the municipal college of the town. He became French master at a school at Stratford-on-Avon in 1839, and in 1840 a pattern-designer at Coventry. But he soon returned to Boulogne, and after taking his degree at Douai (1841) was appointed professor in his native college. His connection with Nestor l'Hôte, the companion of Champollion, directed Mariette's attention to the hieroglyphic monuments; in 1849 he entered the Egyptian department of the Louvre, and in 1850 was despatched to Egypt in search of Coptic MSS. Whilst there

he made his famous discovery of the Serapeum, the long-buried cemetery of the Apis bulls, and brought to light a host of important monuments and inscriptions in Memphis, Sakkara, Giza, and the neighbourhood. In 1858 he was appointed Keeper of Monuments to the Egyptian government, and thenceforward his life was devoted to archaeological exploration in the Nile valley. With indefatigable industry he dug out the Sphinx and the temples of Dendera and Edfu, revealed the marvellous sculptures of Mejdûm and Giza, and the courts and inscriptions of Medinet Habu, Deir-el-Bahri, Karnak, and Abydos, and began the excavation of Tanis. Nor was he less active with pen and pencil. In 1856-57 appeared his *Sérapéum de Memphis* (also ed. Maspero, i. 1882); four editions of his *Aperçu de l'Histoire d'Égypte* came out between 1864 and 1874, and six of the *Catalogue du Musée de Boulak* (which he founded in 1863, and which is full of the results of his labours) from 1864 to 1876; he published sumptuous descriptions in many volumes, with folio plates of the chief temples—*Dendérah* (1870-75), *Abydos* (1869-80), *Karnak* (1875), *Deir-el-Baharî* (1877), *Monuments Divers* (1872 ff.); while his *Itinéraire de la Haute Égypte* was translated by his brother (*Monuments of Upper Egypt*, 1877), and his *Mastabas* edited by Maspero (1882). Besides the Bulaq (now Kasren-Nil) Museum, which owes its existence to its first director, Mariette founded the French School of Egyptology and the Egyptian Institute. He died at Cairo, 19th January 1881.

See E. Deseille, *Aug. Mariette* (1882); H. A. Wallon, *Notice*, Inst. de France (1883); and a biographical notice by Maspero in Mariette's *Œuvres diverses* (i. 1904).

Marignano. See MELEGNANO.

Marigold, a name given to certain plants of the natural order Compositæ, chiefly of the genera *Calendula* and *Tagetes*. Pot Marigold (*Calendula officinalis*) is an annual, a native of France and the more southern parts of Europe, with an erect stem, 1 to 2 feet high, the lower leaves obovate on long stalks, and large, deep yellow flowers. It has long been very common in British gardens; there are varieties with double flowers. The whole plant has a slightly aromatic odour and a bitter taste. The genus *Tagetes* consists of annual and perennial herbaceous plants, natives of the warmer parts of America, although *T. erecta*, one of those most frequently cultivated in Britain, bears the name of African Marigold; and *T. patula*, another annual well known in British flower-borders, is called French Marigold. Both species are Mexican. They have been long in cultivation, are much admired, and require the assistance of a hotbed in spring in the colder parts of Britain. Corn Marigold is a *Chrysanthemum* (q.v.). Marsh Marigold (q.v.) has no botanical affinity with the true marigolds. See also BUR-MARIGOLD.

Marines, or the ROYAL MARINE FORCES, are that body of the military forces of the crown which is under control of the Admiralty for service at sea or on land. The badge of the Royal Marines is the Globe and Laurel, with motto 'Per mare, per terram.' Their colonel-in-chief is the king. A regiment of marines was first raised by the Admiralty in 1664; previous to this troops had been embarked for temporary duty on board ship. In 1755 three divisions were established at Chatham, Portsmouth, and Plymouth. A fourth division was established at Woolwich in 1805, and disbanded in 1869. In 1802, as a reward for its services the corps was, by royal command, created 'the Royal Marines.' In 1855, in consequence of services in the Crimea, the title of 'Light Infantry' was added. In 1804 the Royal Marine Artillery was first authorised, artillery companies being

formed and attached to each division. In 1866 a Royal Marine Artillery division was established at Eastney. An Order in Council of 11th October 1923 amalgamated the Royal Marine Artillery and Royal Marine Light Infantry into the corps of 'Royal Marines.' The titles of 'Gunner R.M.A.' and 'Private R.M.L.I.' were changed to 'Marine.' The recruit depot is at Deal.

When serving in H.M. ships the marines are employed as guns' crews and in gunnery control, the size of the detachment being regulated by the number of guns' crews they are required to provide. In addition they are employed as sentries and in the general duties of the ship. They are equipped in a similar manner to the army, and are always ready for landing for service on shore. They combine the handiness of the sailor with the training of the soldier. They are skilled gunners, and highly trained infantrymen. In order to give marines the necessary training a long-service system is necessary: marines are, therefore, engaged to serve for twelve years, with option of re-engaging for another nine years, when they receive a pension. The result of this is that an unlimited supply of recruits can be obtained. They are carefully selected, both for physique and education. The original number of marines was 1200. The strength of the corps has varied considerably since its formation: at the time of the Napoleonic wars it was 31,000; immediately prior to the European War it was 18,000; at the date of the armistice the strength had reached 58,339.

The marines have been engaged in every war, both large and small, by land and sea, with few exceptions, and have always shown courage and loyalty. In the European War the marines more than upheld the traditions of the corps; 6000 were present in the battle of Jutland. Large numbers were employed as gunners in merchantmen and 'Q' boats. Four battalions of marines were hastily despatched for the defence of Antwerp, but were driven back, eventually composing the rearguard in the retreat of the Naval Division. Early in the war the 63d (Royal Naval) Division was formed, organised, and administered by Headquarters R.M. Forces. Originally there were four battalions of marines in this division; but, after service in Gallipoli, at Seddul Bahr, and Kum Kale, being greatly reduced in strength, the four battalions became two, and were transferred to France with the Naval Division, where they took part in some of the hardest fighting, their casualties being very heavy. Marine battalions were present in the battles of the Somme, Ancre, Arras, Paschendaele, and Cambrai. Their most famous service during the European War was the landing of a battalion on the mole at Zeebrugge to cover the operations by seamen of blocking the canal. Marines also took part in operations in German East and West Africa, Serbia, and North and South Russia. The marines during the war organised the following units: Heavy howitzer brigades (15-inch) with armies in France, battalion in the Aegean islands, armoured-car squadrons, marine engineers, marine submarine miners, marine labour corps, various anti-aircraft, anti-submarine, and coast defence batteries.

See Edye's *Historical Records of the Royal Marines*; Gillespie's *History of the R.M. Corps, 1803*; and Field's *Britain's Sea Soldiers*.

Marinetti, FILIPPO TOMMASO, Italian poet, born at Alexandria in 1881, studied at the Sorbonne, Pavia, and Genoa, edited *Poesia*, and advocated Futurism (q.v.).

Marini, GIAMBATTISTA, an Italian poet, born at Naples in 1569. Abandoning jurisprudence for poetry against his father's will, he was befriended

by various noble patrons, and was carried by Cardinal Pietro Aldobrandini to Turin, where a poem, *Il Ritratto*, procured him the office of ducal secretary. At Paris he enjoyed the patronage of Catharine of Valois, and after her death of Marie de' Medici. Here he wrote his best work, the *Adone* (1622), and after its publication revisited Italy, and died at Naples in 1625. The licentiousness that mars his verse was but an echo of his life. His imitators form the so-called Marinist school, of which the essential features are florid hyperbole and false overstrained imagery. See GONGORA, LYL, and METAPHYSICAL POETS.

Marino, a town on the Alban Hills, 12 miles SE. of Rome, has a castle belonging to the Colonnas, who took it from their rivals, the Orsinis, in 1424, and a cathedral and churches with pictures by Guido, Domenichino, and Guercino. It grows wine, and manufactures soap, leather, &c. Pop. 10,000.

Mario, GIUSEPPE, the famous tenor, was by birth the Cavaliere di Candia and son of General di Candia. He was born probably at Cagliari (not Genoa or Turin) about 1808, and served in the army for some years. But a youthful escapade led to his forsaking Italy for Paris, where he quickly won his way into the most exclusive circles both by the charm of his manners and his exquisite voice. Having contracted debts, however, he accepted the appointment of first tenor of the Opéra, with a salary of 1500 francs per month, changing his name at the same time from De Candia to Mario. After two years' study at the Conservatoire Mario made his début, on the 2d December 1838, as Robert in *Robert le Diable*, and achieved the first of a long series of operatic triumphs in Paris, London, St Petersburg, and America. His repertoire embraced all the great works of Rossini, Bellini, Donizetti, and Verdi. By his wife, the famous singer Giulia Grisi (q.v.), he had several daughters. In private he was esteemed for his large-handed liberality and for his noble assistance to struggling artists. In his later years after his retirement from the stage he lost his fortune through disastrous speculations. He died at Rome, 11th December 1883. See Judith Gautier, *Le Roman d'un Grand Chanteur* (1912).

Mariolatry. See MARY.

Marion, capital of Marion county, Ohio, 46 miles by rail N. of Columbus, with manufactures of machinery, farming implements, and other wares; pop. 28,000.

Marionettes, little jointed puppets of wood or cardboard, especially those moved by means of cords or springs by a concealed agent. From the Greeks they passed to the Romans. In Italy the *Fantoccini* reached a very respectable degree of artistic merit, and still hold their ground. The marionette theatre was carried to France under Charles IX. Thence it passed quickly to England, where it became known as a *motion*, or *motion of puppets*, or *puppets* only. The favourite resort of puppet-plays in London seems to have been Bartholomew Fair, and in Elizabethan times they played set pieces. We find allusions so frequent as to prove wide popularity in Shakespeare, Ben Jonson, Pepys's *Diary*, Pope, Swift, and the Essayists. Marionettes are still exhibited occasionally, but the only very familiar marionette-play we have is the Punch and Judy of our streets. A marionette *Faust* had for many generations been played in Germany, and Goethe tells us that it gave him the first suggestion of his greatest work. Plays have been written in French for the marionette stage by Maeterlinck. In the East the showmen are very frequently Gypsies. Gypsies used to show

marionettes in Germany, and already are spoken of as actors in Scotland in the 16th century. See PUNCH.

Mariotte, EDMÉ, a French physicist, born in Burgundy during the first half of the 17th century—the year is not known—was prior of St Martin-sous-Beaune, and died at Paris, 12th May 1684. He was one of the earliest members of the Academy of Sciences at Paris, and wrote original papers on percussion, the nature of air and its pressure, the movements of fluid bodies and of pendulums, on colours, &c. What is on the Continent called Mariotte's Law is rather Boyle's Law, and is an empirical law stated by Boyle (q.v.) in his *Defence of the Doctrine touching the Spring and Weight of the Air* (1662), and by Mariotte in his *Discours sur la Nature de l'Air* (1676). See GAS AND GASES. Mariotte's collected works were published at Leyden in 1717, and at The Hague (2 vols.) in 1740.

Mariposa, a central county of California, bordering on the Sierra Nevada. It contains the Yosemite Valley (q.v.) and a Sequoia (q.v.) grove.

Maris, JAKOB (1837-99), one of the greatest modern Dutch painters of landscape and genre, was one of three brothers, all born at The Hague. After studying at Antwerp and Paris he settled in Holland. In his earlier stages he painted interiors notable for their great minuteness of detail. His sojourn in Paris developed and broadened his art, however, and it is as a landscape painter of uncommon merit that he is known to fame. In this his later style he subordinated detail to a general grandeur of design, and nowhere is this more strikingly manifest than in 'Dordrecht,' where the massing of light and shade overwhelms detail and leaves the essential grandeur of the scene before us. 'The Stone Mill,' 'Grey Tower, Old Amsterdam,' and 'A Village Scene,' are others of his masterpieces. In all he delighted in showing the effect of light through a silvery mist.—His brother MATTHIJIS (1839-1917) studied with him at Antwerp and Paris, where he was enrolled in the National Guard during the siege. There he painted 'Feeding Chickens' (which shows how the romantic buildings of central France had affected him) and 'Montmartre.' In 1872 he went to London, where he helped the decorative artist Daniel Cottier, but nothing was able to keep the artist in harness. He insisted on painting when he liked and what he liked, and as a result the works of his maturity number only about thirty. He chose to live apart from the world in one of his own making, a world of dreams and poverty. 'The Girl at the Well,' 'Enfant Couché,' 'The Spinner,' and 'The Flower,' are examples of his work which show the great blending of romantic imagination and realistic treatment to which he attained.—WILLEM (1844-1910), the third brother, worked in a different style. Cattle in full daylight, and landscapes with sand-hills and meadows, much brighter and more full of colour than the work of his brothers, were his favourite subjects.

Marischal. See MARSHAL, KEITH.

Marists, a modern French Catholic Congregation (q.v.). The Marist Fathers date from 1815, the Marist Brothers from 1817, and the Marist Sisters from 1834.

Maritza (Gr. *Hebros*), a river of Europe, rises in the Balkans, and flows E. by S. through Bulgaria past Philippopolis, then between Greece and Turkey. At Adrianople it bends and flows S. by W. to the Gulf of Enos in the Ægean. It is 270 miles long, and is navigable for small boats to Adrianople.

Mariupol, or MARIAMPOL, a seaport of the Ukraine, on the Sea of Azov, 65 miles W. of

Taganrog. It was founded in 1779 by Greek emigrants from the Crimea, and exports coal, grain, rape-seed, and iron, and has metallurgical works. Pop. 68,000.

Marius, GAIUS, a famous Roman general who was seven times consul, was born of an obscure family at the village of Cereatæ, near Arpinum, 157 B.C. He served with great distinction at the siege of Numantia (134) under the younger Scipio Africanus, who is said to have hinted that in him the Romans would find a successor to himself. In 119 he was elected tribune of the plebs, and already he had made himself a great popular leader by his vigorous opposition to the nobles. In 114 he went to Spain as proprætor, and cleared the country of the robbers who infested it. He now married Julia, the sister of the father of the great Cæsar. He served in Africa as legate to Q. Cæcilius Metellus during the war against Jugurtha, and was elected consul for the year 107. He took for his province Numidia, and closed the Jugurthine war in the beginning of 106. The honour of capturing the beaten king fell to his quæstor L. Sulla, and from this period dates the birth of that jealousy out of which were to flow so many horrors. Meanwhile, an immense horde of Cimbri, Teutones, and other northern barbarians had burst into Gaul, and repeatedly defeated the Roman forces with great slaughter. Marius was again called to the consulate for the year 104, and for the third, fourth, and fifth time in the following years, 103-101, for it was felt that he alone could save the republic. The war against the Teutones in Transalpine Gaul occupied him for more than two years; but he finally annihilated them in a terrible battle of two days' duration at Aquæ Sextiæ, now Aix, in Provence. That 200,000—or even 100,000—Teutones were slain is of course a gross exaggeration. After this he turned to the Cimbri in the north of Italy, and them he also overthrew at Campi Raudii near Vercellæ, with a like destruction (101). The people of Rome knew no bounds to their joy. Marius was declared the saviour of the state, the third founder of Rome, and was made consul for the sixth time in 100.

When Sulla as consul was entrusted with the conduct of the Mithradatic war, Marius attempted to deprive his patrician rival of the command, and a civil war began (88). Marius was soon forced to flee, and, after the most frightful hardships, and numerous hairbreadth escapes, he made his way to Africa. Two romantic incidents stand out among these days of peril. His place of hiding in the marshes of Liris had been discovered, and he had been flung into prison at Minturnæ, when a Cimbrian slave was sent to despatch him. 'Wretch, darest thou slay Gaius Marius?' said the old hero as he glared upon him out of the gloom. The slave fled in terror saying, 'I cannot kill Marius,' and the citizens recognising the omen allowed the exile to escape. Scarcely had he reached the shore of Africa, when the Roman governor sent him a summons to leave the country. Said Marius, 'Go, tell the prætor that you have seen Gaius Marius a fugitive sitting on the ruins of Carthage.' Here he remained until a rising of his friends took place under Cinna. He then hurried back to Italy, and, along with Cinna, marched against Rome, which was obliged to yield. Marius was delirious in his revenge upon the aristocracy; a band of 4000 slaves carried on the work of murder for five days and nights. Marius and Cinna were elected consuls together for the year 86, but the former died after he had held the office seventeen days. On the triumph of Sulla his body, which had been buried, not burned, was torn from its grave on the banks of the Anio and cast into the stream. Lucan tells us

how the troubled ghost haunted the spot and scared the peasants from the plough on the eve of impending revolutions.

Marivaux, PIERRE CARLET DE CHAMBLAIN DE, was born at Paris, February 4, 1688. He belonged to a good Norman family and devoted himself to letters. He received but a slight education and in his early writings affected a disdain of the Greek and Latin authors, declaring, for example, that he preferred Gregory of Tours to Tacitus and Vincent Ferrier to Demosthenes. He published *L'Homère Travesti*, a burlesque of the *Iliad*, in 1716, and brought out his best comedy, *Le Jeu de l'Amour et du Hasard* in 1730. He received a pension from Helvétius, and another, of 1000 crowns a year, from Madame de Pompadour. His romance of *Marianne* came out in 11 parts between 1731 and 1741, but was never concluded by him, the twelfth part being added by Madame Riccoboni. He followed up his first dramatic success by numerous comedies: *L'Épreuve*, *Les Fausses Confidences*, *Le Legs*, *Les Sincères*, *La Méprise*, *Le Triomphe de l'Amour*, &c. They are the work of a clever analyst rather than a dramatist; the dialogue, says Sainte-Beuve, is a perpetual 'moral skirmish'; the writer sacrifices character and situation to an ingenious playing with words. Marivaux, said Voltaire, knew all the bypaths in the human heart, but he did not know the highway. He died at Paris, February 12, 1763. His title to fame rests on *Marianne*, one of the best novels of the 18th century. Its interest does not lie in exciting adventures, but in the subtle analysis of character and

the delicate picturing of contemporary manners. From the peculiarities of Marivaux's finicking style the term *Marivaudage* was at one time current as a synonym for affected or 'precious' writing. His other romances, *Pharamond* and *Le Paysan parvenu*, are greatly inferior to *Marianne*. See Sainte-Beuve's *Causeries du Lundi IX.*, and Arsène Houssaye's *Galerie de Portraits du dix-huitième Siècle*.

Common Marjoram
(*Origanum vulgare*).

Marjoram (*Origanum*), a genus of plants of

the natural order Labiatae. Several of the species are familiar as pot and sweet herbs in gardens. *O. vulgare* is the Common Marjoram, a native of Britain, and is aromatic with a bitter and slightly acrid taste. The dry leaves have been used instead of tea, and they are also used in fomentations. The tops of the plant have been used to dye woollen cloth purple; and, by a process of macerating the material first in alum water and then in a decoction of crab-tree bark, they also dye cotton cloth a reddish-brown. *Oil of Marjoram* is obtained from this and other species by distillation. The oil of marjoram is so caustic as to be used by farriers as a stimulating liniment. A little cotton moistened with it placed in the hollow of an aching tooth relieves pain. *O. heracleoticum* is the Winter

Sweet Marjoram of gardeners; *O. Onites* is the Pot Marjoram; and the Knotted Marjoram is *O. Majorana*. The dittany of Crete, a plant with round leaves clothed with thick white down and purple trailing stems, which is frequently cultivated as a window-plant in Britain, is *O. Dictamnus*. Several species have been used as sources of thymol and of carvacrol.

Mark, the standard weight of the money system in various countries of Europe, especially in Germany, where in the middle of the 11th century the Cologne mark = half a Cologne pound, or 233·812 grammes, was adopted as the standard, and as such continued in use till 1857. The mark gradually acquired a monetary value as well; as such it has been since 1875 the standard of currency in the German Reich, being normally equal to 11½d. English and 24 cents United States currency. The mark is divided into 100 pfennigs. The Lübeck mark or mark current, a coin formerly in use at Hamburg, was worth 1s. 2d.; the *mark banco* there, a money of account, was worth 1s. 6d. In England marks are first heard of in the treaty between Alfred and Guthrum the Dane, and are supposed to have been then a Danish reckoning. But these marks were not coins, only money of account, or rather a weight. In 1194 the coined mark had the nominal value it ever after retained, 160 pennies or 13s. 4d., two-thirds of the nominal 'pound.' The gold noble, first struck by Edward III., was worth half a mark—6s. 8d. As late as 1703 Defoe was fined 200 marks. In Scotland the mark or *merk* was a weight for gold and silver, or common money reckoning, and also a coin; originally of the same value as in England, it depreciated till in 1625 it had only one-twelfth of the English value. There were two-merk, one-merk (4½ to the oz.), half, and quarter merk pieces. The French standard weight mark weighed 244·75 grammes.

Mark, a signature. See DEED, ILLITERATES.

Mark. See MARCHES, VILLAGE COMMUNITIES.

Mark, the evangelist and reputed author of the second gospel. His original name was John, and Mark (Marcus) was a Latin prænomen used in Gentile circles. In the New Testament he is sometimes called John Mark, sometimes simply John, and sometimes Mark. Little is known about his early life. His mother's name was Mary. She owned a house in Jerusalem, which was used as rendezvous for the early Christians. Mark was the cousin of Barnabas, and, like his distinguished relative, may possibly have been a native of Cyprus and a member of a Levitical family. Through the influence of his mother and his cousin Mark soon came into prominence in the primitive Christian community. When Paul and Barnabas went from Antioch to Jerusalem to bring monetary assistance to the Christians there, on their return they took Mark with them back to Antioch (Acts, xii. 25). Soon afterwards the first missionary journey was planned by the two apostles, and they took Mark with them 'as their attendant' (Acts, xiii. 5). The exact meaning of this phrase is obscure. Chase has suggested that the common interpretation of the words is wrong. The term 'attendant' represents not Mark's relationship to Paul and Barnabas, but his office as 'synagogue attendant.' ('They had with them also John, who was a synagogue official.' Mark was with the apostles during their missionary tour through Cyprus; but when they returned to the mainland, and proposed to extend their work into the interior of Asia Minor, Mark left them and returned to Jerusalem (xiii. 13). No reason is given for his conduct, but we know that Paul deeply resented his defection. Possibly Mark's courage failed him. He was not of the

stuff of which heroes are made. Possibly, as Chase suggests, he did not altogether approve of the policy adopted by the two apostles of accepting Gentile converts into the church. Mark's desertion was all the more serious, because Paul was ill at the time and needed his presence and assistance. It is easy to understand, therefore, how it was that when Barnabas proposed to take Mark on the second missionary journey, Paul refused to have as his companion the man 'who withdrew from them from Pamphylia and went not with them to the work.' A sharp altercation arose between the two apostles on the point, with the result that they separated, and Barnabas returned with Mark to Cyprus, where he is lost to sight for some time. There can be no doubt, however, that the estrangement between Mark and Paul was afterwards removed. In Paul's later epistles we find that Mark was one of Paul's companions during his imprisonment at Rome, and he speaks of him in terms of praise and affection (Coloss. iv. 10-11; Philemon, 24). In the second epistle to Timothy, too, Paul urges Timothy to bring Mark to him with all speed, 'for he is useful to minister to my needs' (iv. 11). We can only conclude from these references that Mark had been completely restored to favour, and was once more warmly attached to the apostle Paul. There may also be a reference to Mark in the salutation of 1 Peter, v. 13, where the writer sends greetings from the church in Rome and 'Mark my son,' and if this be so, it confirms the early tradition preserved in Papias and elsewhere which associates Mark with Peter and describes him as 'Peter's interpreter,' though the meaning of this phrase is not easy to explain. Some scholars, e.g. Zahn, maintain that the word 'interpreter' is used loosely, and refers to the fact that Mark embodied the oral teaching of Peter in a book. Others, on the contrary, hold that the phrase must be used in a natural sense, and that Mark helped Peter by translating his message into Greek and Latin. Later tradition connects Mark with Alexandria. 'He was the first,' says Eusebius, 'to found churches in Alexandria itself.' Two later apocryphal works, (a) the Acts of Mark, (b) the Periods of Barnabas, attempt to fill up the details of tradition. The former describes Mark's work in Alexandria, the latter gives an account of the missionary labours of Barnabas and Mark in Cyprus. Both are unreliable, and it is difficult to sift the grains of fact from the immense overgrowth of legend. The Acts of Mark declare that Mark finally suffered martyrdom at Alexandria, and this statement is endorsed by Jerome, but the tradition is so late (4th century) that it cannot be regarded as trustworthy. It is not likely that such an event would be passed over without mention by the great Alexandrian fathers, and their silence about Mark's work in Alexandria throws discredit on the whole tradition.

Mark, GOSPEL OF. It is now generally agreed amongst modern scholars that the gospel of Mark is the most primitive of the synoptics, and one of the sources which lie at the base of Matthew and Luke (see GOSPELS). This view, however, is of comparatively recent origin. The traditional theory, which goes back to Augustine and Jerome, maintained that Mark was the 'abbreviator and follower' of Matthew. This position was first challenged by G. C. Storr in an essay *Ueber den Zweck der evangelischen Geschichte Johannes*, published in 1786. Storr's hypothesis of the priority of Mark did not at first secure much support. The Tübingen school, for reasons of its own, clung to the traditional view. And even in recent times the position of Augustine has found an ardent champion in Zahn. The modern investigation of the synoptic problem has, however, convinced the

vast majority of present-day scholars that the belief in the priority of Mark rests on irrefragable evidence. Practically the whole of the narrative of Mark (with the exception of a few unimportant sections) is embodied in either Matthew or Luke, or both. The outline followed by Mark is accepted by the other two evangelists, and they never both diverge from it at the same time. Mark's arrangement of incidents, too, is also, generally speaking, followed by Luke and Matthew. The linguistic resemblances are best explained by supposing that Mark was the earliest writer, for it is comparatively rarely that Matthew and Luke agree in phraseology against Mark. The priority of Mark may therefore be regarded as one of the assured results of modern criticism. There is general agreement, too, that Mark's gospel is based upon the reminiscences of Peter. Our earliest testimony upon this point comes from Papias (130-140 A.D.), who says, 'Mark, who had been Peter's interpreter, wrote down accurately all he remembered of the words and acts of Christ, but not in order. For neither did he hear the Lord nor was he one of his followers. He was a follower, as I have said, at a later time of Peter, who arranged his addresses as occasions dictated, without any intention of putting together a complete statement of the Lord's sayings: for of one thing, he (i.e. Mark) was most careful, not to omit anything he heard, nor to misrepresent anything in it.' The only criticism of importance which has been brought against this statement is upon the phrase 'not in order.' As it stands, Mark's chronological arrangement of the narrative seems to be more satisfactory than that of either of the other synoptists, and it seems strange that Papias should pass this stricture upon it. Possibly what Papias means is that Mark did not narrate the events in the order in which they were arranged in Peter's speeches. Possibly, too, he may have had another chronological standard in his mind. He may, for instance, as Lightfoot and others have maintained, be drawing a contrast between the arrangement in Mark and the arrangement in the fourth gospel to the detriment of the former. Burkitt supposes, on the other hand, that the phrase translated 'not in order' does not refer to arrangement at all, but is used in a technical sense, and means 'not with rhetorical display.' The statement of Papias regarding the connection between Mark and Peter is accepted without question by many later patristic writers, and there seems to be no doubt that upon this point tradition is unassailable.

The question which really divides scholars to-day is: Does our present gospel represent the original work of Mark, or is it a later version expanding and embellishing the narrative actually written by Mark? In other words, was there an Ur-Marcus from which our gospel was developed either by Mark himself or more probably by some later writer? This theory has assumed many forms; one of the most interesting hypotheses is the suggestion of Dr A. Wright that the gospel of Mark passed through three stages in the process of its evolution: (1) The first edition, known as Proto-Mark, represents the version of Mark used by Luke; it is difficult to account for Luke's omissions, especially 'the great omission' which extends from Mark, vi. 42 to Mark, viii. 19 if he had our gospel of Mark before him in its entirety as he wrote; (2) the second edition or Deutero-Mark, which represents the version used by Matthew; (3) the third edition or Trito-Mark is equivalent to our present gospel. This theory has been substantially accepted by Professor Stanton, who holds that the three stages in the evolution of the gospel are a demonstrated fact. On the other hand, such important authorities as Sir John Hawkins

and Dr Sanday deny entirely the validity of the theory.

Another question in debate is, Did Mark know and use the collection of Logia, generally described as Q, which formed the source from which Matthew and Luke derived their knowledge of the teaching of Jesus? The affirmative position is maintained by B. Weiss and Streeter, the negative by Harnack, Wellhausen, and Burkitt. On the whole, it may be said that the evidence favours the negative rather than the affirmative position, and it is very difficult to deny Harnack's statement in summing up his discussion of the problem, 'that the evangelist made use of Q no one will be able to prove.' On the kindred problem as to the relative value of Mark and Q, there has been a great controversy within recent years between Harnack and Wellhausen. Wellhausen contends that the supremacy rests with Mark, which is thus our chief and most reliable source, while Harnack, on the other hand, is equally vigorous in maintaining the authority of Q. The conflict of opinion is, however, chiefly of academic interest, since the material of Harnack has very little in common with that of Q, inasmuch as Mark deals mainly with external events, and Q is chiefly occupied with the teaching of Jesus. It is a noteworthy fact, however, that Mark should have found so stalwart and convinced a defender as Wellhausen.

The gospel of Mark consists of a number of graphic and vivid pictures or cartoons of the life of Christ. The writer is fond of introducing pictorial details, as in the account of the healing of the palsied man (ii. 1-12), or the Gadarene demoniac (v. 1-20), or the boy possessed with the evil spirit (ix. 14-25). In the parallel passages of Matthew and Luke the narrative is much balder and more concise. The first nine chapters of Mark are occupied entirely with an account of the Galilean ministry of Jesus. The gospel throughout is a gospel of action rather than of teaching. Comparatively little space is devoted to the words of Jesus, and all the stress is laid upon his deeds. Hence the story is much more dramatic than that of the other synoptics. The present ending of the gospel (xvi. 9-20) is undoubtedly a later addition, and is possibly the work of Aristion, whose name is attached to it in an Armenian MS. discovered by Conybeare. What happened to the original ending cannot be determined. Possibly a papyrus leaf was torn off the roll by accident. Possibly, however, it may have been designedly omitted in order to remove evidence which seemed to conflict with the Johannine account of the Resurrection. A shorter ending is found in some MSS. and printed in many editions of the Greek text as an alternative to the present conclusion of the gospel. Still a third ending is given in the Washington MS., which was discovered in 1907 and published in 1912. The date at which the gospel was written is difficult to determine. The opinion of patristic writers is divided on the point. Irenæus tells us that it was 'after the decease of Peter and Paul' that Mark undertook to embody Peter's teaching in writing. Clement and Origen, on the other hand, state that the gospel was written during the lifetime of Peter, who gave his approval to the book. The *terminus ad quem* is fixed, of course, by the date of Matthew and Luke, but these books unfortunately cannot be exactly dated. There is a good deal of force, however, in the argument of Harnack that Luke must have been written not long after the date at which the narrative in Acts ends (62 A.D.). This position would make 60 the latest possible date for Mark. The eschatological discourses, too, seem to imply a date earlier than the destruction of Jerusalem. The gospel was probably written at Rome (though tradition also assigns it to Alexandria), and was

certainly intended for Gentile readers. This seems to be conclusively proved by the fact that Aramaic terms (e.g. *Talitha cumi*, v. 41; *Effatha*, vii. 34; *Golgotha*, xv. 22) are always explained, and by the presence of frequent Latinisms in the Greek text. Jewish customs and practices, too, are always described in a way which would not have been necessary if the book had been intended for Jewish readers, who were familiar with them.

The best modern commentaries are those of Swete, Gould (*International Critical*), Menzies (*The Earliest Gospel*), Montefiore and Bruce (*Expositor's Greek Testament*), J. V. Bartlet (*Century Bible*). See also Bennett, *The Life of Christ according to St Mark*; J. M. Thompson, *Jesus according to St Mark*. The most valuable modern German commentaries are those of Holtzmann, B. Weiss, Klostermann, and Wellhausen. In French the best commentary is that of Loisy.

Mark Antony. See ANTONIUS.

Market-Drayton, a town of Shropshire, on the Tern, 18 miles N.E. of Shrewsbury. It has a grammar-school, county grammar-school, and a church dating from the 12th century, up whose spire Clive (q.v.) clambered as a boy. At Bloreheath, 3 miles to the east, the Yorkists won a victory in 1459. Pop. 4700.

Market-Harborough, an urban district of Leicestershire, on the river Welland and the Union Canal, 16 miles S.E. of Leicester, has traces of a Roman camp; a fine Perpendicular church, built by John of Gaunt as an atonement for his intrigue with Catharine Swynford, with a broad spire 154 feet high; and the highly picturesque old grammar-school (1614; restored 1869). A famous hunting-centre, it gives title to one of Whyte-Melville's novels. Pop. 8600.

Markets. See FAIRS.

Markham, SIR CLEMENTS ROBERT (1830-1916), son of a canon of Windsor, was born at Stillington, near York, and educated at Westminster. He served in the navy, was in the Franklin Arctic expedition, held posts in the Board of Control and the India Office, and was secretary and (1893-1905) president of the Royal Geographical Society. He travelled much in Peru and India, and from South America introduced the cultivation of cinchona into India (1860); and he was geographer to the Abyssinian expedition (1867). He wrote *Lives of Lord Fairfax, Columbus, John Davis, Major Rennell, and M'Clintock*; histories of Peru, Persia, the Indian surveys, missions to Tibet, and the Abyssinian expedition; travels in Peru and India, and an Inca grammar and dictionary, besides translations. He edited over 20 volumes for the Hakluyt Society, and contributed to *Chambers's Encyclopedia*.

Markham, GERVASE (1568?-1637), earliest English hack writer, served as a soldier in the Netherlands, and wrote copiously on innumerable subjects, as on horsemanship, *Country Contentments*, and the story (in verse) of Sir Richard Grenville, and imported the first Arab horse into England.

Markham, MRS., was the pen-name of Mrs Elizabeth Penrose (1780-1837), who wrote school histories of England and France, and other works for the young. Her father was Edmund Cartwright (q.v.); her husband, vicar of Thorney near Newark, wrote over a dozen theological works.

Markirch (Fr. *Ste-Marie-aux-Mines*), a town of Upper Alsace (Haut Rhin), on the Leber, 40 miles S.W. of Strasburg by rail, with important cotton and woollen mills; pop. 12,000.

Marl, a mixture, naturally existing, of clay and carbonate of lime. Marls are found in very

different geological formations, but everywhere seem to owe their origin to deposition by water. The name is sometimes applied to friable clays, or mixtures of clay and sand, in which there is almost no trace of lime; but the presence of a notable proportion of carbonate of lime is essential to marls, properly so called. This proportion varies from 6 to 20 per cent. Marly soils are in general of great natural fertility. Marl is very advantageously used as a manure, acting both chemically and mechanically; but different kinds of marl are of very different value in this respect. The use of marl as a manure has been practised from ancient times. An English statute of 1225 (10 Henry III.) gave every man a right to sink a marl-pit on his own ground, and there is other evidence that the application of marl to land was common in England in the 13th century. The quicker action and greater efficiency of lime have led to its use in many cases instead of marl, although some kinds of marl are extremely useful in some soils. The bulkiness of marl confines its use to the neighbourhood in which it is found. Marl is sometimes indurated into a rock; a slaty variety, containing much bitumen, is found in Germany. See also LIAS.

Marlborough, an old and interesting market-town of Wiltshire, pleasantly situated in the valley of the Kennet, 75 miles from London; near by is the Savernake Forest, and north of the town lies the wide expanse of the Wiltshire Downs. The broad High Street, with picturesque old houses, has a charm of its own. At the eastern end is St Mary's Church, rebuilt in 1790, but bearing still on its tower the marks of Cavalier bullets. To the west is St Peter's, and a stone's-throw beyond it is the well-known Marlborough College. Pop. 4400. —Marlborough College was incorporated in 1845, and obtained an additional charter in 1853; the nucleus of the college buildings is the 18th-century mansion of the Seymour family, an excellent example of early Georgian domestic architecture, afterwards famous as the Castle Inn. In the college grounds stands a mound which once supported the keep of the Norman castle of Marlborough, and is generally believed to be of Neolithic origin. Among the more recent additions the chapel, opened in 1886, is most worthy of mention. See local histories by Waylen (1854) and Hulme (1881), and the *History of the College* (2d ed. 1923).

Marlborough, a provincial district of New Zealand (q.v.), in the north-east corner of the South Island, 130 miles long by 30 broad.

Marlborough, JOHN CHURCHILL, DUKE OF, the ablest general and diplomatist of his time, was born on the 24th June 1650, at Ashe, in Devonshire, an old manor-house, which can still be seen between Axminster and Seaton. His father, Sir Winston Churchill, had been an enthusiastic adherent of the Stuarts, and on the accession of Cromwell to power his estates had been consequently sequestered. At the Restoration, however, Winston recovered possession of his lands, but his poverty prevented him from giving his children an education befitting their position, so that young Churchill and his brother George had to face the world with little Latin and less Greek, and a knowledge of English history gathered from the plays of Shakespeare. During his engagement as a page to the Duke of York, John was fortunate enough to secure a commission as ensign in the Guards, and at the age of sixteen, in the year 1667, he was sent to Tangiers, then besieged by the Moors. It is said that he was sent to Tangiers on account of the king's jealousy of his favour with the Duchess of Cleveland; and the story is told that on one occasion, being nearly surprised by the king, he leapt out

of a window and was presented by the duchess with £5000, £4500 of which he invested in an annuity of £500 a year. The papers with regard to the annuity transaction are still in existence. At Tangiers Churchill had little opportunity of distinguishing himself. Recalled to England by the Duke of York, he was promoted to a captaincy, and in command of a grenadier company he was despatched to join Turenne, to assist Louis XIV. in the reduction of the fortresses on the Dutch frontier. Here his brilliant courage and ability at once gained him a colonelcy, although his promotion would not have been so rapid had he not called into requisition the influence of his sister, Arabella, mistress of the Duke of York. His prosperity was further advanced by his marriage with Sarah Jennings, a lady as remarkable for her talents and imperious disposition as for her beauty. In 1682 he was created Baron Churchill of Eyemouth, in Scotland. On the accession of the Duke of York to the throne as James II., the services of Colonel Churchill to his master were not forgotten, as he was raised to the English peerage under the title of Baron Churchill of Sandridge, in Hertfordshire. Promoted to be general, Churchill took an active part in quelling the rebellion of Monmouth; but, on the landing of the Prince of Orange, he joined the invader. James's daughter, the Princess Anne, accompanied by Lady Churchill, also fled to join the rebels in the north. William, on his accession, showed his gratitude for the assistance given him by Churchill by creating him Earl of Marlborough. Notwithstanding the conspicuous service rendered by Marlborough in reducing Ireland to subjection, and as commander of the troops employed against the French in the Netherlands, in 1689-91, William III. could not rid himself of a certain not altogether ungrounded suspicion of his new earl, till in 1692 he fell into disfavour, and was dismissed from all his offices. As the result of the discovery of a plot with which a clever forger named Young associated the name of Marlborough, the earl was arrested and lodged in the Tower. In ten days he was released, however, but for five years he was without any public employment, till the death of Mary, when he was restored to the favour of the king, and he retained it till the death of William in 1702.

At the accession of Queen Anne he was entrusted with the command of the British army in the Netherlands on the declaration of the war of the Spanish succession, in which he was to show his unrivalled strategical genius during one of the greatest series of military operations in which England has ever been engaged. Anne showered honours on the head of the fortunate earl and his wife, her closest friend. Marlborough was made a knight of the Garter, Commander-in-chief, and Master General of the Ordnance, while his lady was appointed Groom of the Stole, Mistress of the Robes, and Keeper of the Privy Purse. Marlborough, in fact, became regent in all but name. His wife governed the queen, and he himself directed Godolphin, the Lord High Treasurer, whose son had married his daughter. At the opening of the campaign, Marlborough, on his arrival at The Hague, was named commander-in-chief of the combined English and Dutch forces, with a salary of £10,000. The campaign was one long series of triumphs for the allies. In 1702, for driving the French out of Spanish Guelders, the reward was a dukedom and £5000 per annum 'from the post-office.' He was summoned to the campaign in the Low Countries, in which he was so much disgusted with the Dutch that he returned to England, seriously thinking of throwing up his command. Next year, however, we see him supporting the German Emperor and joining Prince Eugene of Savoy, in July

of that year storming successfully the French and Bavarian lines at Donauwörth, and on the 13th August gaining a glorious but bloody victory over the enemy at Blenheim. Of 56,000 men, the French and Bavarians lost 40,000, and the victors' killed and wounded numbered fully 12,000. The result of this decisive battle stamped Marlborough as the first general in Europe. Parliament bestowed upon him the estate of Woodstock, the queen caused Blenheim Park (q.v.) to be built for him, and the emperor created him a prince of the Holy Roman Empire. Diplomatic negotiations occupied the principal part of Marlborough's time and attention in 1705, but in 1706 he resumed that career of victory which broke the force of the spell surrounding the great power of France under Louis XIV., who gloried in calling himself the 'Invincible.' On the 23d May 1706 the battle of Ramillies was fought, when the French were obliged to desert the line of the Scheldt and evacuate the whole of Spanish Flanders. The campaign of 1707 was an almost wholly inactive one; but in 1708 the attempt by the French under Vendôme to recover Flanders led to the battle of Oudenarde—the only battle of Marlborough's engaged in front of a fortified town—fought on July 11, and resulting in the total defeat of the French forces. Marlborough then laid siege to Lille and Ghent, and the surrender of these two towns ended the long and arduous campaign. The year 1709 was distinguished by the battle of Malplaquet—in Marlborough's words, 'a very murdering battle.' The numbers were practically equal, but the French had an infinite superiority of position. There are few battles in history of which it can so certainly be said that the best men won. The carnage was tremendous—20,000 on the side of the allies and 8000 on that of the French. The blood of Malplaquet—the last of the four engagements which gave Marlborough's name a unique position in the roll of generals—did not bring about peace; and in 1711 he was afield again, taking town after town from the French. This eventually led to the treaty of Utrecht, which gave thirty years of peace to Europe.

Meanwhile important events were taking place in Britain. The queen, tired of the tyranny exercised by the Duchess of Marlborough, shook off the yoke, dismissed her ministers, Godolphin and Sunderland, paving the way for the elevation to power of the Earl of Oxford and the Tories. Thereupon a charge was preferred against Marlborough of having embezzled public money, and he was deprived of his offices, till the accession of George I., when, in a day, he was restored to the position in which he stood after the battle of Blenheim. A stroke of apoplexy on 28th May 1716, although it impaired his speech, did not preclude his attendance in parliament till within six months of his death, which occurred on 16th June 1722. His funeral obsequies in Westminster Abbey were celebrated with great magnificence, and all ranks and all parties in the state joined in doing him honour. Charges of avarice and peculation have been brought against Marlborough—among others, by Hallam, Mahon, Macaulay, and Thackeray. Despite this, and the certainty that he thought more of his own interest than the cause in which he was engaged, his character had many elements of excellence. He was generous in action, gentle in temper, a devoted husband, and a man of religious fervour.

His wife, SARAH JENNINGS, was born on 29th May 1660, and when about twelve years of age entered the service of the Duchess of York, and became the chosen and most intimate friend of her step-daughter the Princess Anne. Like Marlborough

himself, Sarah came of an ancient but ruined royalist family. On the accession of Anne to the throne, the duchess exercised over the young queen the influence due to a superior and singularly active mind. Her power was almost boundless; the Whig ministry relied upon her support, and she disposed of places and offices at her pleasure. Her rule, which lasted for a considerable time, at last became unbearable, and she was supplanted in the favour of the queen by her own cousin, Mrs Masham, whom she herself had introduced to court. She retired from the queen's service in January 1711; and for nearly a quarter of a century she survived her husband, living in complete retirement. She was of a very pugnacious disposition, only happy when quarrelling with her friends or engaged in lawsuits, such as those arising out of the completion of Blenheim. She died on 29th October 1744, leaving a fortune of three millions—sterling, of which she bequeathed £10,000 to William Pitt. As the Marquis of Blandford, the only son of the Duke and Duchess of Marlborough, died young, the title was inherited by the descendants of one of their daughters, the Countess of Sunderland.

Comm.) for the intrigue with the Duke of Berwick; books by Thomas (1915), and on the Duchess by Katherine Thomson (1839), F. Molloy (1901), Olivia Colville (1904), and S. J. Reid (1913).

Marlitt, E., the pseudonym of EUGENIE JOHN, German novelist, who, born at Arnstadt in Thuringia 5th December 1825, was educated by the Princess of Schwarzburg-Sondershausen for the stage. She appeared first at Vienna, after three years of study there; but a successfully-begun career was cut short by an affection of the ear, and thereafter she acted as reader to her patroness till 1863. Retiring in that year into private life, she spent her time in writing romances, interesting enough, but with strong didactic tendencies and somewhat unreal. She died at Arnstadt on 22d June 1887.

Marlow, GREAT, a town of Buckinghamshire, on the Thames, 29 miles W. of London by rail, has a brewery and paper-mills, an iron suspension bridge, a house where Shelley lived in 1817, and a grammar-school (formerly a blue-coat school). It sent two members to parliament down to 1867, and one till 1885. Pop. 5000.

Marlowe, CHRISTOPHER, Shakespeare's greatest predecessor in the English drama, a shoemaker's son, was baptised at Canterbury, 26th February 1563-64. From the King's School, Canterbury, he was sent to Benet College (now Corpus Christi), Cambridge, and proceeded B.A. in 1583. How he employed himself after taking his bachelor's degree is not known. Absence from Cambridge and rumours concerning him were apparently influencing the university authorities against him and threatening to delay his commencing M.A.; but the Privy Council interposed (1587) with a certificate of good behaviour and valuable service to the state, and he graduated a few days later.

The earliest of Marlowe's extant plays is *Tamburlaine the Great*, in two parts, first printed in 1590, and probably produced in 1587. In spite of its bombast and violence it is infinitely superior to any earlier tragedy of the English stage. By his energy and fervour, his aspiring imagination and majestic utterance, he confounded his rivals and won immediate supremacy. Very noticeable is the proud self-confidence displayed by the young poet in the prologue:

From jiggling veins of rhyming mother-wits,
And such conceits as clownage keeps in pay,
We'll lead you to the stateliest tent of war,
Where you shall hear the Scythian Tamburlaine
Threatening the world with high astounding terms.

Earlier dramatists had employed blank verse, but it had been stiff and ungainly: Marlowe was the first to discover its strength and variety. The popularity of *Tamburlaine* was extraordinary. A ludicrous line in the Scythian conqueror's address to the captive monarchs whom he has harnessed to his chariot—'Holla, ye pampered jades of Asia!'—was constantly parodied for half a century. Doubtless the extravaganzas of the play contributed to its success. The part of *Tamburlaine* was originally taken by the famous actor, Edward Alleyn, who afterwards personated Faustus and Barabas.

The Tragical History of Dr Faustus was probably produced soon after *Tamburlaine*. The earliest edition is dated 1604; in the edition of 1616 additional comic matter is inserted by an inferior hand, but it also appears to preserve some genuine passages that were dropped from the earlier edition. *Faustus*, as it has come down, is rather a series of detached scenes than a finished drama; and some of these scenes are evidently not by Marlowe. One playwright after another was employed to furnish 'additions.' But the nobler scenes are marvellously impressive; nowhere is Marlowe's genius shown more vividly than in Faustus's glorious description of Helen's beauty and in the terrible soliloquies that prepare us for the catastrophe. *Faustus* held the stage, and was revived at the Restoration. Edward Phillips, Milton's nephew, quaintly remarks that 'Of all that Marlowe hath written to the stage his *Dr Faustus* hath made the greatest noise, with his devils and such like tragical sport.' A German version was acted by English players at Gratz during the carnival in 1608, and at Dresden in 1626. Goethe expressed his admiration for Marlowe's work.

The Jew of Malta, produced after December 1588, was first published in 1633, with a prologue by Thomas Heywood. It is a very unequal play. The first two acts are conducted with masterly skill and vigour; but the last three are absurdly extravagant, degenerating into vulgar caricature. If Marlowe's hand had not faltered, if the later part had been equal to the earlier, Barabas would have been worthy to stand alongside of Shylock.

Edward II., produced about 1590, is the maturest of Marlowe's plays. It has not the magnificent poetry that we find in *Faustus* and in the first two acts of *The Jew of Malta*, but it is planned and executed with more firmness and solidity—in a more temperate and patient spirit. The various characters are skilfully discriminated, and the action is never allowed to flag. Many critics have preferred it to Shakespeare's *Richard II.*; it is certainly no whit inferior. Charles Lamb declared that 'the reluctant pangs of abdicating royalty in Edward furnished hints which Shakespeare scarce improved in his *Richard II.*'; and the death-scene of Marlowe's king moves pity and terror beyond any scene, ancient or modern, with which I am acquainted.

The Massacre at Paris is the weakest of Marlowe's plays, and has descended in a mutilated state. It was written after the assassination of Henry III. of France (2d August 1589), and was probably one of the latest plays. An early MS., a fragment of an original playhouse transcript, preserves part of scene xix.; and a comparison of the MS. text with the text of the printed copy shows that the play was mangled in passing through the press.

The Tragedy of Dido is stated on the title-page of the first edition (1594) to have been written by 'Christopher Marlow and Thomas Nash, Gent.' Probably it was left in a fragmentary state by Marlowe and was finished by Nash. It is of slight value; but contains some fanciful poetry (and extraordinary bombast). There can be little

doubt that Marlowe had a hand in the three parts of *Henry VI.*; and it is probable that he was concerned in the authorship of *Titus Andronicus*. A wild, shapeless tragedy, *Lust's Dominion*, was published in 1657 as the work of Marlowe. It deals with historical events that happened after Marlowe's death, but may nevertheless have been adapted from one of Marlowe's lost plays.

The unfinished poem, *Hero and Leander*, composed in heroic couplets of consummate beauty, was first published in 1598; a second edition, with Chapman's continuation, followed in the same year. Ben Jonson is reported to have said that Marlowe's verses were examples fitter for admiration than for parallel. From a passage in the Third Sestiad it appears that Marlowe had enjoined upon Chapman the task of finishing the poem; but neither Chapman nor any other poet could have taken up the story with any hope of success. *Hero and Leander* passed through numerous editions, and won universal applause. Shakespeare quoted in *As You Like It* the line, 'Who ever loved that loved not at first sight?' and feelingly apostrophised the poet as 'Dead Shepherd.' Nash, in *Lenten Stuffe*, speaks of 'divine Musæus, and a diviner poet than him, Kit Marlowe.' The watermen sang couplets from it as they plied their sculls on the Thames. Henry Petowe, a poor versifier but enthusiastic admirer of Marlowe, tells how

Men would shun their sleep in still dark night
To meditate upon his golden lines.

Marlowe's translations of Ovid's *Amores* and of the first book of Lucan's *Pharsalia* add nothing to his fame. The pastoral ditty 'Come, live with me and be my love,' to which Sir Walter Raleigh wrote an Answer, was imitated, but not equalled, by Herrick, Donne, and others. Izaak Walton pronounced it to be 'choicely good.' It was first printed in *The Passionate Pilgrim* (1599), without the fourth and sixth stanzas. In *England's Helicon* (1600) it appeared complete, with the author's name, 'C. Marlowe,' subscribed. Another anthology, Allot's *England's Parnassus* (1600), preserves a fragment by Marlowe, beginning 'I walked along a stream for pureness rare.'

In May 1593, at the age of twenty-nine, Marlowe was stabbed at Deptford in a quarrel (about a tavern reckoning) with one Ingram Frizer, 'gentleman,' and 'then and there instantly died' according to the coroner's jury. Highly-coloured accounts of his death were given by Puritanical writers. Thomas Beard, in the *Theatre of God's Judgement*, declares that 'hee even cursed and blasphemed to his last gaspe, and together with his breath an oath flew out of his mouth.' In Harleian MS. 6848 is a note 'containing the opinion of on Christopher Marly concerning his damnable judgment of religion and scorn of Gods word,' drawn up (shortly before Marlowe's death) by a certain Richard Baines, who was hanged at Tyburn, 6th December 1594. The same manuscript contains fragments of a theological disputation which Thomas Kyd, seeking to clear himself of the charge of atheism, asserted to have been written by Marlowe and to have been shuffled among his own papers. Marlowe's atheism seems to have been rather a variety of unitarianism or theism.

Had his life been lengthened, Marlowe would doubtless have written more perfect tragedies, but he could hardly have left a better poem than *Hero and Leander*. Comedy he would never have attempted; he had no humour. In tragedy he prepared the way for Shakespeare, on whose early work his influence is firmly stamped.

Dyce's scholarly edition of Marlowe's works (3 vols. 1850; revised ed. 1 vol. 1858) has not been superseded. Cunningham's edition (1 vol.) is useful but inaccurate. In 1885 A. H. Bullen, and in 1910 Tucker-Brooke,

brought out editions. Marlowe's best plays are included in the 'Mermaid' series, ably edited by Havelock Ellis. *Dr Faustus* was elaborately edited by Sir A. W. Ward. See, besides Ward's *History of Dramatic Literature* (2d ed. 1899) and Symonds's *Predecessors of Shakespeare* (1884), books on Marlowe by Verity (1886), Lewis (1891), J. H. Ingram (1904), Fischer (Munich, 1889), Hotson (1925, for new facts), and the texts of several plays edited in Germany by Wagner and others.

Marmion, SHACKERLEY, minor dramatist, was born in Northamptonshire, January 1602, studied at Wadham College, Oxford, and took the degree of M.A. in 1624. He squandered his fortune, fought in the Low Countries, and joined Sir John Suckling's troop for the expedition against the Scots, but fell sick at York and returned to London, where he died early in 1639. He left behind an epic, *Cupid and Psyche* (in Saintsbury's *Caroline Poets*), and three comedies, *Holland's Leaguer*, *A Fine Companion*, and *The Antiquary*. The last form a volume (1875) in Maidment and Logan's *Dramatists of the Restoration*. The ancient family of the Marmions of Scrivelsby were the former hereditary champions at English coronations. They came in with the Conqueror and settled at Tamworth, but became extinct with the fifth baron under Edward I. Scott says of the hero of his poem, 'I have not created a new family, but only revived the titles of an old one in an imaginary personage.'

Marmont, AUGUSTE FRÉDÉRIC LOUIS VIESSE DE, Duke of Ragusa and Marshal of France, was born 20th July 1774 at Châtillon-sur-Seine, entered the army at an early age, and made the acquaintance of Napoleon at Toulon. He accompanied him to Italy, where his courage at Lodi, Castiglione, and San Giorgio, earned him the rank of general of brigade in the campaign of Egypt. He returned with Bonaparte to France, supported him in the revolution of the 18th Brumaire, and commanded his artillery at Marengo, after which he became general of division. He was sent to Dalmatia in 1805 to defend the Ragusan territory against the Russians, defeated them at Castelnovo, and was made Duke of Ragusa. Hence he was summoned to join the great army in 1809, the day before the battle of Wagram, was entrusted with the pursuit of the enemy, won the battle of Znaim, and earned a marshal's baton. He was thereafter for eighteen months governor of the Illyrian provinces; and in 1811 succeeded Masséna in the chief command in Portugal, where he showed skilful strategy in the presence of Wellington. A severe wound, received at the defeat of Salamanca, compelled him to retire to France. In 1813 he commanded a *corps d'armée*, fought at Lützen, Bautzen, and Dresden, and maintained the contest with great spirit in France in the beginning of 1814, till further resistance was hopeless, when he concluded a truce with Barclay de Tolly, which compelled Napoleon to abdicate, and earned himself from the Bonapartists the title of the traitor. The Bourbons loaded Marmont with honours. On the return of Napoleon from Elba he was obliged to flee. After the second restoration he lived in retirement till the revolution of 1830, when, at the head of a body of troops, he endeavoured to reduce Paris to submission, and finally retreating with 6000 Swiss, and a few battalions that had continued faithful to Charles X., conducted him across the frontier. From that time he travelled much and resided chiefly in Vienna and Venice, where he died, 2d March 1852. He was the last survivor of the marshals of the first French Empire. His chief work is his *Esprit des Institutions Militaires* (1845). His *Mémoires* fill nine volumes (1856-57). See Sainte-Beuve, *Causeries du Lundi*, vol. vi.

Marmontel, JEAN FRANÇOIS, a famous but

hardly a great French writer, was born of an obscure family at Bort, in the Limousin, 11th July 1723. He made his studies in a Jesuit college, and found employment in a seminary at Toulouse, but early turned to literature, and went to Paris in 1745 by advice of Voltaire. Here he wrote successful tragedies and operas, and was fortunate enough in 1753 to get a secretaryship at Versailles through the influence of Madame Pompadour. Soon after he received a more lucrative appointment, the official journal, *Le Mercure*, being entrusted to his charge. In its columns he commenced the publication of his finished and oft-translated *Contes Moraux* (1761). Marmontel was elected to the Academy in 1763, and became its secretary in 1783, as well as Historiographer of France. After the Revolution he retired to the village of Abbeville, near Évreux, where he died, 31st December 1799. His most celebrated work was the well-known *Bélisaire*, a dull and wordy political romance, containing a chapter on toleration which excited the most furious hostility on the part of the Sorbonne, to which Marmontel replied in *Les Incas* by ascribing the cruelties in Spanish America to religious fanaticism. In 1787 appeared his interesting, but completely uncritical, *Éléments de Littérature*, consisting of his contributions to the *Encyclopédie*. A selection from his *Moral Tales* was edited by Professor Saintsbury (1895). His *Mémoires* is an interesting survey of his whole life, brightened by glimpses of all the great figures he had seen cross the stage from Massillon to Mirabeau.

His own edition of his complete works fills 17 volumes (1786-87), to which must be added 14 volumes published posthumously. Good editions are those of Villeneuve (1819-20) and Saint-Surin (1824-27). See Sainte-Beuve's *Causeries du Lundi*, vol. iv., and a book by Lenel (1902).

Marmora, LA. See LA MARMORA.

Mar'mora, SEA OF, the *Propontis* of the ancients, separating Europe from Asia, and connecting the Aegean Sea by the Dardanelles (anc. *Hellespont*) with the Black Sea by the Bosphorus. It is of an oval form, is 175 miles in length by 50 in breadth, has an area of 4499 sq. m., and a maximum depth of 4250 feet. The Gulf of Ismid extends about 30 miles eastwards into Asia. The sea contains several islands, the largest of which is Marmora or Marmara (area, 50 sq. m.), famous for its quarries of marble and alabaster.

Marmoset, a name given to a group of American monkeys which are always of small size, and which differ in various particulars from other American monkeys (see MONKEY). The popular name of Ouistiti has been given to these monkeys on account of the sharp whistling sound which they make when frightened or irritated. There are a good many species of marmosets which are placed in two genera, *Midas* and *Hapale*, both confined to Central and South America. These creatures are easily kept in captivity, and are usually of an affectionate disposition.

Marmot (*Arctomys*), a genus of rodents, belonging to the family Sciuridae, resemble squirrels in their dentition, although in form and habits they more closely resemble rats and mice. They have two incisors and two premolars in each jaw, four molars on each side above, and three below.—The Common Marmot, or Alpine Marmot (*A. marmotta*), is a native of the Alps, the Pyrenees, and the more northern mountains of Europe, up to the limits of perpetual snow, and is found also in Asia. It is about the size of a rabbit, grayish-yellow, brown towards the head; feeds on roots, leaves, insects, &c.; and is gregarious, often living in large societies. Marmots spend the winter in their burrows, in one chamber of which is a store of dried grass;

but the greater part of the winter is passed in a torpid condition. The Alpine Marmot is easily tamed. There are three kinds of marmots in

The Alpine Marmot (*Arctomys marmotta*).

North America, all popularly termed 'Woodchucks.' The 'Prairie Marmot' (see PRAIRIE DOG) is nearly allied, but not of the same genus.

Marne, a river of France, the most considerable tributary of the Seine, rises in the plateau of Langres, flows north-west past Châlons to Épernay, and thence west, joining the Seine at Charenton, a few miles above Paris. Its length is 326 miles, and it is navigable for 126 miles up to St Dizier. Its stream is rather rapid, and in most places has a wide bed. It is connected by canals with the Rhine, the Aisne, and the Seine. It gives name to two battles (September 1914, July 1918) in the Great War (q.v.).

Marne, a department in the north-east of France, formed out of the old province of Champagne, is traversed by the river Marne, and to a less extent by the Seine and the Aisne. Area, 3159 sq. m.; pop. (1921) 366,734. It is in the dry and chalky soil of the north that the best varieties of Champagne Wine (q.v.) are grown, and much of this is exported. The rearing of sheep is an important industry, and extensive woollen manufactures are carried on. Cereals, beetroot, and potatoes are grown; honey and wax are produced; building stone is quarried; and metal works, tanneries, &c., are in operation. Marne is divided into the five arrondissements of Châlons-sur-Marne (the capital), Épernay, Reims, Sainte-Ménéhould, and Vitry-le-François.

Marne, HAUTE, a department in the north-east of France, formed chiefly out of the old province of Champagne, and embracing the upper basins of the Marne and the Meuse. It rises in the south into the plateau of Langres and the Monts Faucilles (1500 to 1600 feet). Area, 2402 sq. m.; pop. (1921) 198,865. Cereals, wine, fruits, and potatoes are the principal products. The department yields iron ore, and there are numerous furnaces. The cutlery is in high repute. There are three arrondissements of Chaumont, Langres, and Vassy; capital, Chaumont.

Marnix, PHILIP VAN, Lord of St Aldegonde, Dutch writer and patriot, was born at Brussels in 1538. A pupil at Geneva of Calvin and Beza, on his return home he took an active part in promoting the Reformation, and in 1566 a no less active part in the revolt of the Netherlands against Spain. An intimate friend of William of Orange, he was appointed by him to be his representative at the first meeting of the Estates of the United Provinces, held at Dort in 1572, and on subsequent occasions was sent on special missions to the courts of France and England. After helping to cement the Union of Utrecht and visiting

the diet at Worms, he was nominated in 1583 burgomaster of Antwerp. This city he defended thirteen months against the Spaniards; but, having then capitulated, he incurred so much ill-will that he retired from public life. The leisure of his retirement he utilised for literary work, besides taking an active interest in the newly-founded university of Leyden. From his pen came the *Wilhelmus* song, the hymn of Dutch liberty and Protestantism; the epoch-making prose satire on the Roman Catholic Church, entitled *The Roman Bee-hive* (1569); a metrical translation of the Psalms from the Hebrew (1580); and the beginning of a prose translation of the Bible. Marnix died at Leyden, 15th December 1598. His works were edited in 7 vols. (Brussels, 1855-59); his religious works in 2 vols. (The Hague, 1871-78). See *Lives in Dutch* by Broes (1840) and *Frédéricq* (1882), and the French monograph by Juste (1858).

Marocco. See MOROCCO.

Marochetti, CARLO, BARON, an Italian sculptor of respectable talent, was born at Turin in 1805, and trained in Bosio's studio. Settling at Paris, he produced 'Young Girl sporting with a Dog,' 'Fallen Angel,' relief on the Arc d'Étoile, an altarpiece for the Madeleine, a memorial work for Bellini's tomb, a statue of Latour d'Auvergne, &c. On the outbreak of the revolution in 1848 he repaired to London. In Britain his best works were statues of Queen Victoria for Glasgow, of Richard Cœur-de-Lion and of Lord Clyde in London. Mounted figures of Emmanuel Philibert and Charles Albert of Savoy were chiselled by him for North Italy. He died at Passy, near Paris, on 29th December 1867.

Maronites, a Christian sect of Syria, generally regarded as the descendants of a remnant of the Monothelite sect (see MONOTHELISM), who settled on the slopes of Lebanon in the 7th century. They take their name from a monk Maro, who lived in the 5th century, or more probably from their first patriarch Moro (701). These people maintained their independence against the followers of Islam; but in the 12th century, on the establishment of the Latin kingdom of Jerusalem, they abandoned their distinctive monothelite opinions, and recognised the authority of the Roman Church. In 1445 they entered into a formal act of union with the Roman Church; in 1584 a college was founded in Rome by Pope Gregory XIII. for the education of the Maronite clergy; and in 1736 they formally subscribed the decrees of the Council of Trent. Nevertheless, they retain their distinctive national rites and usages, and use the ancient Syriac language in their liturgy; their clergy, if married before ordination, are permitted to keep their wives; and they have many festivals and saints not recognised in the Roman calendar. The Maronites, a sturdy, warlike race of mountaineers number about 400,000 (half in Lebanon). Their patriarch (of Antioch), who is elected by their bishops, subject to the approval of Rome, resides at Bekorki in Lebanon. Many convents for both sexes are spread over the country, especially in the neighbourhood of Bsherreh, above Tripoli; the inmates follow the rule of St Anthony. The relations of the Maronites with their implacable foes, the Druses, have been already detailed under DRUSES and LEBANON.

Maroons, the name (derived from the Span. *cimarrón*, from *cima*, 'a mountain top') given in Jamaica and Guiana to fugitive negro slaves. When the British took Jamaica from the Spaniards in 1655, numbers of slaves took refuge in the uplands. They and their descendants, called Maroons, maintained a constant warfare with the colonists for 140 years; but in 1795-96 they were

subdued, and a portion of them removed to Nova Scotia, and afterwards to Sierra Leone. The remnants after 1834-35 fraternised with their brethren, in these years manumitted. The Maroons of Guiana, who are generally called Bush Negroes, form a number of independent communities. See Dallas, *History of the Maroons* (1803).

Maros-Vásárhely, capital of the Szekler districts in Transylvania, stands on the Maros, 28 miles SE. of Klausenburg. It contains a fortified castle, an old Gothic church (Reformed), a library, and a collection of minerals and antiquities, and has a trade in timber, tobacco, wine, corn, and fruit (particularly melons). Pop. 18,000.

Marot, CLÉMENT, a distinguished French poet of the time of Francis I., was born at Cahors in 1496 (?). Largely owing to the influence of his father, who was both poet and courtier, he began at an early age to write verses, and, abandoning his legal studies, entered the service of Margaret, Duchess of Alençon, afterwards Queen of Navarre, to whom many of his poems are addressed. He was wounded at the battle of Pavia in 1525, and at the end of the year was imprisoned on a charge of heresy, but was liberated in the spring of 1526. Having a witty pen and a satiric turn, and not being particularly prudent either in speech or conduct, he made many enemies and gave his royal patrons considerable trouble. During his absence from Paris in 1535 his house was searched, and compromising literature was found in his library. His claim that a poet should be permitted to read everything being disallowed, he fled, first to the court of the Queen of Navarre, and later found refuge with the Duchess of Ferrara. He returned to Paris in 1536, and in 1538 began to translate the Psalms, which in their French dress became very popular, especially at the court, where they were sung to favourite secular airs, and helped to make the new views fashionable at least. He was encouraged by the king to continue his translation, but the part published in 1541 having been condemned by the Sorbonne, he had again to flee in 1543. He made his way to Geneva, but, finding Calvin's company uncongenial, he went to Turin, where he died in 1544. His poems consist of elegies, epistles, rondeaus, ballads, songs, sonnets, madrigals, epigrams, nonsense verses, and longer pieces of a general character; and, though he himself tells us that love was above all his master, his special gift lay in the direction of badinage and graceful satire. Marot has a singularly light touch, and a great power of simple natural expression, and in all his poems—if we except some early rhetorical exercises—there is the distinctive style *Marotique* which has had an important influence on French literary language. Though he was persecuted for his religious views, he expressly declares that he was not a Lutheran, and probably like many of his friends—Dolet for instance—he had no very definite theological beliefs.

See *Œuvres Complètes* (4 vols. Paris, 1873-75); *Œuvres Choiesies*, an admirable selection (Paris, 1826); *Life by Vitet* (1868); Douen, *Clément Marot et le Psautier Huguenot* (2 vols. 1879); and Guiffrey's elaborate edition (vols. i.-iii. 1876-1909).

Marozia, a Roman lady of noble birth, but of infamous reputation in the scandalous chronicles of her age, daughter of the equally notorious Theodora, was born in the close of the 9th century. As the mistress of Pope Sergius III., and mother of Pope John XI., she exercised the greatest influence on the political affairs of her time in Italy. She was also grandmother of Pope John XII. She was married three times, and, if we may credit the narrative of Luitprand, had skill and address enough to procure the deposition and

death of Pope John X., and subsequently the elevation of her son as John XI. Marozia's later years brought on her the punishment of her crimes. She died in prison at Rome in 938.

Marprelate Controversy, a bitter war of vigorous and often scurrilous pamphlets, waged against official Episcopacy by a few Elizabethan Puritans. Many of these were written by deprived ministers, but were published under the comprehensive name of Martin Marprelate. The time of greatest activity was about 1589, and the books were printed in spite of severe government repression, successively at Moulsey near Kingston-on-Thames, Fawsley in Northamptonshire, Norton, Coventry, Welstone in Warwickshire, and in or near Manchester. The chief writers were, according to some, John Penry (hanged), John Udall (left to rot in jail), Fenner, John Field, and Job Throckmorton, who wrote *Hay any Work for Cooper?* One of the best attempts to answer the Marprelate writers was Bishop Cooper of Winchester's *Admonition to the People of England*. Other writers on the same side were John Lyly and Thomas Nash. Bacon presented to the ministry in 1590 his wise paper entitled *An Advertisement touching the Controversie of the Church of England*, an admirable argument for moderation and mutual concession in things indifferent. 'First of all,' he says, 'it is more than time that there were an end and surcease made of this immodest and deformed manner of writing lately entertained, whereby matters of religion are handled in the style of the stage.'

See Arber's reprint of the tracts; Maskell's *Marprelate Controversy* (1845); the *Cambridge History of English Literature*; and for the theory that Sir Roger Williams wrote the 'Cooper' tracts, J. Dover Wilson's *Martin Marprelate and Shakespeare's Fluellen* (1912).

Marque. See LETTER OF MARQUE.

Marquesas Islands, or MENDANAS, are a Polynesian group N. of Tuamotu or Low Archipelago. The name strictly applies to four or five islands discovered by Mendaña in 1595, but usually includes now the Washington group of seven islands to the north-west. Total area, 492 sq. m. The whole archipelago is volcanic. Hiva-oo and Nuka-hiva are the largest islands. Nearly all are shaped into several narrow valleys, in which the bulk of the population live. In Cook's time there were 100,000 inhabitants, but they have steadily decreased in numbers till now they are barely 3000. They are perhaps the finest race of the brown Polynesian stock, and, though courteous, are cruel and revengeful. Since 1842 the islands have been a French protectorate. Herman Melville sojourned in Nuka-hiva (see *Typee* and *Omoo*); and Gauguin partly assimilated himself to the natives of Hiva-oo. A little cotton is grown by Chinese immigrants.

Marquetry. See INLAYING.

Marquette, capital of Marquette county, Michigan, is on the southern shore of Lake Superior, 430 miles by rail N. of Chicago. It has foundries, blast-furnaces, &c., besides sawmills and machine-shops. Iron ore in very large quantities is mined in the county and shipped from here. Marquette is the seat of a Roman Catholic bishop. Pop. 13,000.

Marquis, or MARQUESS, the degree of nobility which in the peerage of England ranks next to duke. Marquises were originally commanders on the borders or frontiers of countries, or on the sea-coast, which they were bound to protect. In England there were marquises or lords-marchers of the borders of Scotland and Wales in the reign of Henry III., and the equivalent *Markgraf* was common on the Continent; but the

first English marquis in the modern sense was Robert de Vere, Earl of Oxford, who was created Marquis of Dublin by Richard II. in 1385. The title was first introduced into Scotland in 1599, when the Marquises of Huntly and Hamilton were created. For the coronet of a marquis, see CORONET. The mantle is scarlet, with three and a half doublings of ermine. A marquis is styled 'The Most Honourable'; his wife is a marchioness; his eldest son takes by courtesy the next lower title in the peerage, except where that is identical with the title of the marquise, in which case he must take the next lower still. The younger sons of a marquis are styled 'Lord,' and daughters 'Lady,' with the addition of Christian name and surname.

Marr. See MAR.

Marrakesh, or MOROCCO, southern capital of Morocco, in the French protectorate, stands 5 miles from the left bank of the Tensift, 1447 feet above the sea. A dilapidated wall, more than 5 miles in circumference and between 20 and 30 feet high, includes not merely narrow, unpaved, filthy streets, flanked by flat-roofed, windowless houses, but ill-kept gardens, open areas, and 'soks,' or market-places; the eight large cemeteries are outside the walls. In the bazaar and merchants' quarter—the 'Kaiseria,' a partially-covered area—a considerable local trade is carried on with the country-people, the mountaineers from the neighbouring Atlas, and with Sus, Tafilet, Mazagan, Saffi, and Mogador, though the commercial importance of Morocco is much less than that of Fez. Marrakesh possesses many mosques, one of which, the Kutubia, has a tower after the model of the Hassan in Rabat and the Giralda in Seville, 230 feet high; all three towers are said to have been designed by the same architect, Jabir. There are several tanning and leather-dyeing establishments of considerable extent. The population according to the census of 1921 was about 140,000, including 2000 Europeans. On the south, outside the walls, stands the imperial palace, an irregular conglomeration of gardens and buildings covering about 180 acres.

Marrakesh was founded in 1072 by the Emir Jusef ben Tachefyn, and reached the summit of its prosperity in the 13th century. In those days it is affirmed to have contained more than 700,000 inhabitants. But for several centuries, owing to civil wars, during which the rebellious Berbers more than once sacked it, the city, like all the interior towns of Morocco, rapidly retrograded. However, owing to its excellent situation in sight of the Atlas, from which cool streams are always flowing, its genial healthy climate, and its command of the trade routes across the mountains, its possibilities of development are great.

Marriage (from Lat. *mas*, male; *maritus*, married—literally, provided with a male, and so must originally have been used of women only; *maritus*, husband; *marita*, married woman), the union of man and woman in the relation of husband and wife, as recognised by law or custom. Westermarck has defined marriage (rather from the point of view of natural history than anthropology) as a more or less durable connection between male and female, lasting beyond the mere act of propagation till after the birth of the offspring.

In addition to European (monogamous) marriage, numerous other forms of sexual relationship are found, and others are assumed by theorists to have existed. It was postulated by Lewis Morgan and J. F. M'Lennan that promiscuous sexual intercourse was originally the rule. From this state of *Promiscuity* they derived another form, *Regulated Promiscuity*, in which restrictions of various kinds, classed together under the head of exogamous rules, limited the choice of both men and women by

excluding near kin (either in the male or in the female line in any given tribe). Neither of these stages can properly be denominated marriage, and neither has been shown to exist, except (as in Melanesia) as a secondary stage of development, or a purely temporary condition.

As the first kind (in logical, not historical order) of marriage we may distinguish *Polygamy*, the union of several men with several women, found among the Dieri of Australia and elsewhere. This stage is subdivided into (i.) simple and (ii.) adelphic; in the adelphic stage the male spouses are brothers or the female spouses sisters, or both these conditions may be found. It is further classified according to the position of the husbands, for it may happen that one husband or one wife holds a position superior to his or her mates.

Of more importance than the foregoing is *Polyandry*, which J. F. M'Lennan attributed to the scarcity of women caused by infanticide. In this form of marriage one woman is the wife of several men, who form one household; they may be brothers, as in the Tibetan form, but may also be unrelated. In Tibet, at the present day, scarcity of women is not the cause of polyandry, which probably depends on economic causes, for a large number of women are unable to find husbands. The so-called Nair polyandry of the Malabar coast is really a form of promiscuity, now apparently almost extinct (see Thurston, *Tribes and Castes*, 1909; s.v. NAYAR).

In *Polygyny*, widely spread outside Europe, one man is the husband of several women simultaneously.

Finally we have *Monogamy*, in which one man and one woman are united in marriage, though, owing to facilities for divorce, the bond is now far from permanent in many countries. Even in countries where polygyny is practised, the large majority of men must usually be monogamous, and it is no uncommon thing in West Africa to find men who have never married at all.

Among primitive peoples there are periods of ritual licence, in which ordinary marriage rules and ties are disregarded. These free unions may be classed, according to the circumstances, under the heads of promiscuity, free love, *cicisbeism*, &c.

All known peoples recognise marriage prohibitions, dependent on (a) kinship regulations (see KIN), or (b) exogamous rules. In the former case, consanguinity and affinity are the bars to marriage; in the latter, it is forbidden to members of a totem clan or of the moiety of a tribe to marry within their own social group (see TOTEMISM).

As a correlative to Exogamy we have Endogamy, the rule of the Indian caste, which forbids a man to marry outside a certain social group. It should be noted that the social groups to which the rules of exogamy and endogamy apply are not the same. The Todas, for example, are organised in two endogamous groups, subdivided into exogamous clans; a man may therefore choose among a portion only of the women of his own half of the tribe. The rules of exogamy and endogamy are obligatory, and it is erroneous to term a tribe endogamous when all that is meant is that a tribesman usually marries a fellow-tribeswoman.

At least six kinds of endogamy may be distinguished—ethnic, linguistic, local, functional, sectarian, and social; in theory, all the members of each of these groups are a body of kindred. Another important rule is known as Hypergamy; this is the custom which forbids a woman to marry a man of a group lower than her own. It is a custom of great antiquity, and was one of the causes of infanticide. Other important usages in India are: (a) Infant marriage, which implies the marriage of a woman before puberty; this custom is not infre-

quent in West Africa also; (b) the prohibition of marriage of widows, which led to the rite called *suttee* or *sati*; the word really means a widow who immolates herself on her husband's funeral pyre. In India, it is clear, the accident of birth determines irrevocably the whole course of a man's and, still more, of a woman's domestic relations.

Marriage ceremonies may be almost unknown, as in Australia, where one way of obtaining a wife, though an unusual one, is to knock the woman on the head with a club and drag her off. More normal methods are betrothal, often in infancy, exchange of sisters, purchase, and elopement.

A. E. Crawley (*Mystic Rose*, 1902) was the first to lay stress on the magical significance of marriage ceremonies, which he explained as intended to neutralise the dangers associated by primitive peoples with sex and sexual acts. In these beliefs we may see the origin of the religious ceremony of marriage.

Marriage has, however, also a legal aspect; accordingly, there are also legal requirements to be fulfilled which may entirely replace the religious ceremony. The Romans recognised three modes of taking a wife—*confarreatio*, the religious ceremony; *coemptio*, a legal ceremony of wife-purchase; and *usus*, simple cohabitation, uninterrupted for a year. By all of these methods a wife originally became one of her husband's family. In the marriage *sine conventionione*, consent only was necessary, and the wife remained a member of her own family (see FAMILY).

Much stress was laid by M'Lennan on marriage by 'capture,' which he supposed to result from scarcity of women, and to lead to the existence of exogamy. The scarcity of women is not proven, still less the steps by which M'Lennan imagined that a group which supposed its women to be too valuable to give to strangers, and hence married them to group-mates, eventually reached a stage in which group-mates were forbidden to intermarry. Dr Rivers showed that in Melanesia marriage by capture, which is rarely more than formal, may well have been a means of deceiving the old men of the husband's moiety in order to escape from their monopoly of the younger women; the claim of the old men may have been evaded by a show of force in seizing the girl, and the pretence kept up, long after the trick was apparent, for magical or other reasons. In other cases, as we have seen above, violent capture is known. Capture must also always have been an episode of warlike operations, but in this last comparatively frequent case we do not find a motive for the formal capture on which most of the theories have been built up. Formal marriage by capture is clearly a part of the internal regulations of a tribe or group, and quite unconnected with an original hostile attitude of two distinct groups.

See Bibliography to KIN; Westermarck, *History of Human Marriage* (1921), *Marriage Ceremonies in Morocco* (1914); Malinowski, *Family among Australian Aborigines* (1913).

The nature of marriage, as a social and legal institution, has varied with varying civilisation. The union of a man and woman, to be recognised as a marriage, must be concluded in accordance with the rules laid down by custom or law. Polygamy, in the form of polygyny or of polyandry, has been and is recognised as marriage in many parts of the world. But the only kind of marriage which the law of Christian countries recognises is one which is essentially the voluntary union for life of one man with one woman to the exclusion of all others. A marriage which is not strictly monogamous, though it may pass by the name of marriage, is not the status which the law of Christendom contemplates as marriage. Thus, when a system of

law allows polygamy, a marriage contracted under that system, even in the case of a first wife, is a different relation from monogamous marriage, and is not regarded by English law as a marriage.

In primitive times marriage very often consisted in the forcible capture of the woman by the man. This ancient practice left traces in the ceremonies observed in the celebration of marriage in later generations. Thus, in many of the forms of marriage in use within historical times among the most civilised peoples, sham fighting between the bridegroom or his family and the bride's family, or some form of resistance offered by the bride, continued to form part of the wedding ritual. But, while marriage by capture was undoubtedly a widespread practice, and recognised as a form of marriage, it is doubtful whether it ever was the normal method of contracting marriage among any people. The evidence points rather to its being an incident of war or a method of procuring a wife when it was difficult or inconvenient to get one in the ordinary manner. Marriage by purchase, or the practice of giving the father or other relatives of the bride some valuable consideration in the form of money or goods, seems to have been an almost universal practice. In some cases, as illustrated in the story of Jacob and Laban, the prospective husband, instead of paying money or delivering goods, might work for the woman's father for a certain period. In early times the purchase, or the giving of some valuable consideration for the consent of the bride's father or relatives, was a real transaction, and marriage by actual purchase still obtains among various primitive peoples. But with the progress of civilisation it tended more and more to become merely symbolic. The forms of marriage by purchase long survived among the Egyptians, the Babylonians, the Hebrews, the Greeks, and the Romans. Among the higher races of mankind the tendency, from very early times, has been wholly in the direction of regarding the consent of the parties as the essential element in the constitution of marriage. Marriage by mutual consent of competent persons, possible only when the individuality of the woman has received recognition, takes the form of a mutual and voluntary conveyance, or dedication, of the one to the other. The interchange of consent has been very generally associated with some religious observance. In most modern systems of law—the law of Scotland being in this respect exceptional—marriage is, as a rule, valid only when performed in the manner prescribed, and in the presence of persons recognised, by the state. While the matrimonial status is entered upon, in modern times, in pursuance of an agreement between the parties, accompanied by certain religious or civil formalities, the incidents of the status and the rights of the persons invested with it are regulated by fixed rules of law, and in no sense depend upon the agreement of the parties either at the time of the marriage or subsequently.

From the earliest times certain bars or prohibitions in respect of intermarriage have been enforced by custom or law. On the one hand, there were rules—known as 'endogamous' rules—forbidding the members of a particular tribe or class to marry any one who was not a member of that tribe or class. Thus among the Hindus the intermarriage of persons belonging to different castes is forbidden. In the Mosaic law marriages between Israelites and Canaanites were prohibited—a prohibition subsequently extended so as to include the other Gentile nations. In early times there could be no valid marriage between a Roman citizen and a woman who was not herself a Roman citizen, or who did not belong to a community possessing the privilege of *connubium* with Rome. On the other

hand, there were rules—known as ‘exogamous’ rules—forbidding the members of a particular group to marry any other member of that group. In the evolution of the more civilised peoples the endogamous rules tend to become relaxed and to disappear, and the exogamous rules undergo gradual transformation, and become narrowed down to a prohibition of marriage between near relatives.

Mutual promises to marry or engagements to marry are plainly distinguishable from marriage itself. In Rome marriage was generally preceded by the ceremony of betrothal (*sponsalia*). The betrothal in early times took the form of a verbal contract (*sponsio*). Hence the betrothed persons were *sponsus* and *sponsa*. Afterwards it seems to have been usual for the father of the woman to enter into a stipulation with the man, giving a right of action in case of non-performance. In the later Roman law *sponsalia* were entered into without any formalities, and could be repudiated at will by either party. If, however, *arrhæ* had been given as evidence of the engagement, the party who broke off the engagement without good reason forfeited the amount of the *arrhæ*. In Roman law an engagement to marry does not seem to have been in itself actionable. In Canon law *sponsalia per verba de futuro* created an obligation to marry enforceable by ecclesiastical censures. In England and Scotland promise of marriage, given in exchange for the promise of the other party, is binding. Performance is not enforced, but damages may be recovered for breach of promise. It is not necessary that the promise should be proved by writing, nor even that the mutual promise should be made in express words. The plaintiff cannot recover unless his or her testimony is corroborated by some other material evidence. A general promise to marry is construed as a promise to marry within a reasonable time on request. If a promise to marry is made by a person who, to the knowledge of the other party, is already married, an action for damages for non-fulfilment of the promise will not lie. It is a defence that the promise was induced by fraud or serious misrepresentation on the part of the plaintiff in regard to his or her circumstances and previous life. The unchastity of the woman after the date of the promise, or before the date of the promise, provided the defendant was not aware of it at that date, justifies the non-fulfilment of the promise.

Roman Law.—The essentials of monogamous marriage are tersely expressed in the definition in Justinian's Institutes: *Viri et mulieris conjunctio, individuum vitæ consuetudinem continens.*

Marriage in early Roman law was intimately associated with *manus*—the power over the wife. It is indeed probably true that in Rome, from the earliest historic times, marriage was constituted by the mutual consent of the parties, and that the forms of marriage *cum manu* were modes of creating *manus* rather than modes of constituting marriage. But under the old rules of *jus civile* it was only a marriage *cum manu* that was recognised as a lawful Roman marriage (*justæ nuptiæ*). The forms of marriage *cum manu* were (1) *confarreatio*, (2) *coemptio*, (3) *usus*. *Confarreatio* was a religious ceremony, competent only to patricians, carried out in the presence of the *pontifex maximus* and *flamen dialis* as well as of ten citizen witnesses. *Coemptio* was a purely secular proceeding, consisting in the formal sale (*mancipatio*) of the wife to the husband in the presence of five witnesses. *Usus* was a mode of acquiring *manus* on the principle of *usucapio* (possession). If a woman lived with a man as his wife continuously for one year she at the end of that period came in *manum viri*, and a valid marriage *ex jure civili* was thereby constituted. A wife in *manu* was in entire subjection

to the power of her husband as the head of the family. All the property which she had at the date of the marriage, and anything she acquired during the marriage, passed to her husband.

It was through the form of marriage *usu* that marriage was dissociated from the *manus* which in early times accompanied it. The Twelve Tables provided that a woman by absenting herself from the conjugal home for three consecutive nights (*trinoctium*) in the year could interrupt the *usucapio*, and so prevent *manus* being established. Such a *trinoctium* of absence, repeated year by year, permanently prevented *manus* from arising in respect of the cohabitation. Before the end of the republican period marriage *sine manu* was not only recognised by law as valid, but had become the normal form of marriage among citizens. In the marriage *sine manu* the central principle, as regards the personal relations of the spouses, was that of partnership, *consortium omnis vitæ*. Each of the spouses was the consort of the other, the *consortium* involving a true reciprocity of rights and duties. Marriage, in the classical era of Roman law and down to the time of Justinian, was constituted simply by the mutual consent of the parties, *Nuptias non concubitus sed consensus facit* (Dig. 50, 17, 30, 1). The ordinary methods by which the consent was publicly manifested were *deductio in domum*, the bringing of the bride to the bridegroom's house; the drawing up of *dotalia instrumenta*, constituting the *dos* and containing other marriage contract provisions; and, under the Christian emperors, celebration *in facie ecclesiæ*. The consent not only of the parties but also of their respective *pateres familiae* was necessary. Both the parties must have attained the age of puberty, which, in the time of Justinian, was finally fixed, in the case of males, at fourteen years, and, in the case of females, at twelve years. No legal marriage could be contracted unless there was *connubium* between the parties. Until the Lex Canuleia (445 B.C.) there was no *connubium* between patricians and plebeians. In the classical law the *jus connubii* was a privilege pertaining only to citizens. In the mature law, when all free inhabitants of the empire were citizens, the *connubium* lost its former importance. Marriage was prohibited between persons related to each other by blood in the direct line or in the collateral line nearer than the fourth degree. Propinquity of relationship between two persons in the collateral line was computed by reckoning the number of generations from the one person up to the common ancestor and from the common ancestor down to the other person—each generation counting a degree. Marriage, speaking generally, was lawful between persons related to each other collaterally in the fourth or any more remote degree. Marriage was prohibited between persons related by affinity in the direct line and, under Constantine, between a man and the widow of his deceased brother or the sister of his deceased wife. In the earlier law there existed certain impediments to marriage based on a difference in the rank of the respective parties, but such impediments were swept away by Justinian (Nov. 117, c. 6). Other impediments were based on public policy—e.g. a provincial governor or his son could not marry any woman domiciled in that province during his term of office.

Canon Law.—The Canon law made important contributions to, and changes in, the law governing the forms, attributes, and conditions of marriage. Under the Roman Empire the marriage law of the church was subordinate to the civil law and civil jurisdiction; and for some centuries after the fall of the empire the same conditions continued, and the church only exercised a disciplinary power with

regard to marriage. After the 10th century the church acquired legislative control and complete jurisdiction over marriage. After the Reformation the Canon law rules continued to be a guiding force, not only in Catholic countries but also, subject to certain modifications and differences of interpretation, in Protestant countries. Thus in England, after the Papal jurisdiction was abolished it was enacted that the king might appoint a Royal Commission to examine the Canon law, but that meantime the existing canons should stand in so far as not contrary to the laws of the realm; and, as the contemplated revision was never carried out, the Canon law, as it stood, remained binding. The Christian Church had from the first recognised the validity of Roman law, and the Canon law of marriage was based largely on Roman law, modified by principles developed from interpretations of Christian doctrines. Under the Canon law marriage is a sacrament, indissoluble under any circumstances. The church, however, adopting from Roman law the maxim *consensus facit matrimonium*, upheld as valid marriages resting merely on the agreement of the parties. Marriages not celebrated *in facie ecclesiæ* were, however, irregular, and visited with ecclesiastical penalties. Finally, the Council of Trent, which met at intervals from 1536 to 1563, laid down that for a valid marriage consent must be declared before a priest and in the presence of witnesses. The 'irregular' marriages of Scots law (*vide infra*) are survivals of the older Canon law obtaining prior to the decrees of the Council of Trent. Under the Canon law there were numerous disabilities which prevented the formation of a valid marriage. In England the disabilities resulting from consanguinity and affinity, which were formerly canonical, were made civil disabilities by the Marriage Act, 1835. The only disability which continues in England to rest on Canon law is the physical incapacity of either of the parties to consummate the marriage.

England.—For a valid marriage the full and free consent of the parties is necessary. A marriage, though in form duly celebrated, can be set aside by decree of the court if there is no real consent to the marriage. The age at which a person is capable of giving the necessary consent to marriage is fourteen years in the case of males and twelve years in the case of females. Where either of the parties is a minor—i.e. above the age of matrimonial consent and under twenty-one—the consents required to his or her marriage are now regulated by the Guardianship of Infants Act, 1925 (15 and 16 Geo. V.), sect. 9 and relative schedule (see PARENT AND CHILD). But the consent of the proper person has been held to be directory only, and the want of it does not render the marriage celebrated without it invalid. Where the parent or guardian of a person under twenty-one (not being a widower or widow) openly expresses dissent at the time of proclamation of banns, the publication of banns is void. Lunatics and persons of unsound mind are incapable of consent. Unsoundness of mind in one of the parties at the time when a marriage purports to be contracted is a ground on which the marriage may be declared null, provided that it is such as to render him or her incapable of understanding or appreciating the nature of the contract and the duties and responsibilities thereby created. In such a case a decree of nullity may be obtained at the instance either of the sane or of the insane party. The physical incapacity of either of the parties to consummate the marriage may be made the ground of a suit at the instance of the other party for annulling the marriage. Undue proximity of relationship between the parties, whether by blood or by marriage, renders the marriage null and void (see AFFINITY, CONSANGUINITY). By

the Marriage Act, 1835 (5 and 6 Will. IV. chap. 54), marriage is prohibited (1) between persons lineally related; (2) between collaterals, whether of the whole blood or of the half-blood, to the third degree inclusive, according to the Roman law mode of computation—viz. brother and sister, uncle and niece, nephew and aunt; (3) between persons who, by reason of the previous marriage of one of them, are related by affinity within the corresponding degrees, lineal or collateral. Marriage with a deceased wife's sister was rendered legal by the Deceased Wife's Sister's Marriage Act, 1907, and the marriage of a woman with her deceased husband's brother was rendered legal by the Deceased Brother's Widow's Marriage Act, 1921; but both these statutes contain provisions relieving clergymen from the duty of celebrating such marriages. A valid subsisting marriage of either of the parties renders void any form of marriage between them (see BIGAMY). This is so although there is an honest belief in the death of the existing wife or husband, or although the circumstances are not such as would sustain an indictment for bigamy.

The forms and ceremonies necessary to the validity of a marriage are now regulated by statute. There are two main forms of marriage, viz. (1) marriage by a minister of the Church of England after the publication of banns or the grant of a licence by a Church of England authority; (2) marriage upon obtaining the certificate of the superintendent district registrar of marriages, with or without a licence.

(1) In a marriage according to the religious rites and ceremonies of the Church of England the preliminary to the celebration of the marriage is, either the publication of Banns (q.v.) upon three successive Sundays in the church or churches of the parish or parishes wherein the parties reside; or, in lieu thereof, a licence from the proper ecclesiastical authority. Such a licence may be a 'special' licence, granted by the Archbishop of Canterbury through his vicar-general, or a 'common' licence, granted by the bishop of the diocese through his surrogate. A marriage, after publication of banns, must be solemnised in the church or chapel, or one of the churches or chapels, in which the banns were published, and a marriage by common licence in the church or chapel specified in the licence. The marriage must take place within three months after banns, or grant of a common licence, in the presence of two or more witnesses in addition to the minister, and between the hours of eight in the forenoon and three in the afternoon. A special licence may authorise the marriage to be solemnised at any convenient hour or place, as, for instance, in a private house. Before a licence for marriage is granted one of the parties must make a declaration on oath that there is no legal impediment to the intended marriage; that one of the parties has resided for the space of fifteen days immediately preceding within the parish; and that, in the case of persons under twenty-one, the necessary consent to the marriage has been obtained. Prior to the Marriage Act, 1836, all marriages taking place in England, except where both the parties were Quakers or Jews, had to be solemnised according to the rites of the Church of England, after publication of banns or the procurement of a licence from the proper ecclesiastical authority dispensing with the publication of banns. Under the act of 1836 a marriage may, on production of a superintendent registrar's certificate, be solemnised according to the rites of the Church of England without banns, the certificate standing in the place of the publication of banns; but a minister of the Church of England is not obliged to accept such certificate in the place of the publication of banns, nor may a marriage be solemnised

in pursuance of such certificate in any church or chapel of the Church of England without the consent of the minister thereof (Marriage and Registration Act, 1856, sect. 11).

(2) The Marriage Act, 1836 (6 and 7 Will. IV. chap. 85), amended in subsequent acts, enables all persons to be married according to such religious rites as they deem fit, or without any religious rites, upon obtaining the certificate of the superintendent district registrar of marriages. The superintendent registrar may issue certificates for marriages, without the publication of banns, according to the rites of the Church of England; or for marriages according to the usages of the Quakers or of the Jews; or for marriages in buildings duly registered for the solemnisation of marriages; or for purely civil marriages, without religious ceremony, in the superintendent registrar's office. The certificate may be either a certificate without licence or a certificate with licence.

Where a marriage is intended to be solemnised under a registrar's certificate without licence, notice of the marriage must be given in the prescribed form to the superintendent registrar of the district or districts in which the parties reside. If both the parties reside in the same registration district, and have both resided there for seven days immediately preceding the giving of the notice, the notice may be given by either party. If the parties reside in different registration districts, notice must be given by each to the registration officer of the district in which he or she resides, and the preliminary residential qualification of seven days' residence must be fulfilled by each before the notice is given. The notice of marriage states the names and descriptions of the parties, the dwelling-place of each party, and the length of time during which he or she has resided there, and the church or other building in which the marriage is to be solemnised. It also sets out that the marriage is to be without licence. The notice contains a declaration, subscribed by the person giving the notice, that there is no legal impediment to the marriage; and when either party, not being a widower or widow, is under the age of twenty-one, that the consent of the persons whose consent to the marriage is required by law has been duly given. The notice is entered by the registrar in a Marriage Notice Book, which is open to public inspection. The notice, or a copy of the notice, is suspended or affixed by the registrar in a conspicuous place in his office during twenty-one successive days next after the day on which it was entered in the Marriage Notice Book. If during this period no valid objection is stated, the registrar issues a certificate. The marriage may then take place within three calendar months from the date of the entry of the notice. The building in which the marriage takes place must be that specified in the notice and certificate. The marriage may be solemnised according to the rites of the Church of England. The church in which the marriage takes place must be situated within the district of the superintendent registrar by whom the certificate is issued, the consent of the minister being obtained. Or the marriage may be solemnised in some building certified as a place of religious worship and registered for the solemnisation of marriages. There must be present, in addition to two witnesses, either the registrar or some duly 'authorised person.' Under the Marriage Act, 1898, the presence of a registrar of marriages is not necessary at marriages in Nonconformist registered buildings. That act, which does not apply to marriages according to the usages of the Jews or of the Society of Friends, makes provision for the appointment of an 'authorised person' (usually the minister of the chapel). The rules now govern-

ing the registration of buildings for the solemnisation of marriages and the appointment of 'authorised persons' are set out in Statutory Rules and Orders, No. 1332, dated 4th October 1909. If the presence of a registrar is required at a marriage in a registered building for which an authorised person has been appointed, the fact must be stated when notice of the marriage is given, and the consent of the minister or trustees to the registrar's attendance must be obtained. The ceremony must take place with open doors between the hours of eight in the forenoon and three in the afternoon. The parties must, at some part of the ceremony, declare, in prescribed words, that they take each other as husband and wife. If the marriage is solemnised according to the usages of the Jews or of the Society of Friends it is not necessary that the building in which the marriage is celebrated should be registered or be situated within the district or either of the districts in which the parties reside, and the provisions as to open doors, the presence of witnesses, and the hours during which the marriage may be solemnised have no application. If both parties are Jews they may marry, according to their usages, in a synagogue or private dwelling-house at any hour. If both the parties are members of the Society of Friends, or if, not being members, they have been authorised by the Society of Friends to solemnise their marriage in accordance with its usages, they may be married in a Friends' meeting-room. The presence of a registrar of marriages is not necessary at such marriages of Jews or Quakers. Where the marriage is to be solemnised without religious rites it may take place at a register office in the presence of the superintendent registrar and of a registrar of marriages of the district. It must be solemnised with open doors, in the presence of two witnesses, and between the hours of eight in the forenoon and three in the afternoon, and the same declaration and prescribed form of contracting words must be used as in the case of a marriage at a registered building. No religious service may be used at a marriage in a register office; but if the parties desire to go through a religious ceremony afterwards, they may do so on production of a certificate of the register office marriage.

Where a marriage is intended to be solemnised on a registrar's certificate with licence, notice is given to that effect and a certificate is obtained. But the procedure is different in important respects from that required in the case of a marriage on a registrar's certificate without licence. One notice only is necessary, whether the parties live in the same or in different registration districts, and either party may give the notice. The declaration subscribed to the notice must state that the person giving it has, for the space of fifteen days immediately preceding, had his or her usual place of residence within the district of the registrar to whom the notice is given. When the parties live in the districts of different superintendent registrars it is sufficient that the notice be given to the superintendent registrar of the district in which one of the parties resides, and it is not necessary to state how long each of the parties has resided in his or her dwelling-place, but only how long the party residing in the district in which the notice is given has so resided. The notice need not be suspended in the office of the registrar. After the expiration of one whole day from the day of the entry of the notice of marriage, the certificate, together with a licence to marry, will be issued, provided that no lawful impediment has been shown and the issue of the certificate has not been forbidden. The marriage may take place within three calendar months from the date of the entry of the notice of marriage. No licence can be granted by the super-

intendent registrar for a marriage in any church or chapel in which marriages may be solemnised according to the rites of the Church of England.

A marriage upon the certificate of a registrar (whether with or without licence) cannot be solemnised in any building registered and certified for religious worship without the consent of the minister or one of the trustees or managers thereof, or, in the case of the Church of Rome, of the officiating minister thereof. As to registration of marriages, see REGISTRATION.

Statutory provision is made in the Foreign Marriage Act, 1892 (55 and 56 Vict. chap. 23), for the solemnisation in foreign countries of marriages between persons, one of whom at least is a British subject, by or before marriage officers. Marriages under this act are now regulated by the Foreign Marriages Order in Council, 1913. The persons entitled to act as marriage officers are British ambassadors or members of the diplomatic service authorised in writing by the ambassador, and British consuls or other officers authorised by a warrant from the Secretary of State. A marriage may also be solemnised under the act on board one of His Majesty's ships on a foreign station before the commanding officer of the ship. The act further expressly recognises the validity of marriages celebrated within the lines of a British army serving abroad, by a chaplain or officer or other person officiating under the orders of the commanding officer. The Marriage of British Subjects (Facilities) Acts, 1915-1916, passed to facilitate marriages between British subjects resident in the United Kingdom and British subjects resident in other parts of His Majesty's dominions and in British protectorates, provides for the mutual recognition of certificates of the publication of banns or of notice of marriage issued in the United Kingdom or in those dominions to which the acts have been applied.

The English doctrine on the international validity of marriages is that the law of the parties' domicile decides the question whether, apart from forms and ceremonies, the marriage is valid, and that the law of the place of celebration governs the forms and ceremonies with which the marriage must be solemnised. The law of the domicile of each party must be satisfied as regards capacity to contract the marriage, whether absolute or relative in respect of the prohibited degrees of consanguinity or affinity. Where, however, the domicile of one of the parties is English and the marriage is celebrated in England, the English courts do not regard the validity of the marriage as affected if the law of the domicile of the other party imposes an incapacity not recognised by English law.

Scotland.—The law of Scotland with regard to the conditions or disabilities which prevent the formation of a valid marriage is substantially identical with that of England. In Scotland, however, the consent of the parents or guardians is not necessary to the validity of the marriage of persons who are in minority. Again, an old Scots Act, 1620, chap. 20, declares null a marriage contracted by a divorced spouse with the person with whom he or she has been declared in the decree of divorce pronounced by the Judge Ordinary to have committed adultery; but in practice it is usual to omit the name of the paramour in the decree. As regards the forms of marriage or the methods of contracting marriage, the rules of Scots law are in important respects markedly different from those of English law.

In Scotland a 'regular' marriage is one celebrated *in facie ecclesie*, i.e. in presence of a minister of religion, after either proclamation of banns or publication in accordance with the Marriage Notice Act, 1878. For proclamation of banns each of the

parties intending to marry hands to the session-clerk of the parish in which he or she has resided for at least fifteen days immediately preceding an application, giving the requisite particulars, and a certificate of residence signed by two householders. If the parties reside in different parishes, proclamation must be made in the churches of both parishes. After proclamation has been duly made a certificate to that effect is issued by the session-clerk, and is authority to a clergyman of any denomination to celebrate the marriage. The marriage may be solemnised at any time within three months thereafter. The marriage must take place before at least two witnesses. It need not be celebrated in a church, but may be in a dwelling-house or elsewhere, and at any hour. As an alternative to proclamation of banns the Marriage Notice Act, 1878, enables a regular marriage to be celebrated after publication of notice, as prescribed in the act, and upon production of a registrar's certificate of such publication. Both parties must have resided in Scotland for at least fifteen days prior to publication of the notice. The notice to the registrar states the name, the rank or profession, the condition (whether a bachelor or spinster, widower or widow), the age, and the dwelling-place of the parties, and contains a declaration that the party giving the notice knows of no impediment to the marriage, and has resided within the registrar's parish or district for fifteen days immediately preceding. Two householders in the parish or district must sign a declaration that they believe the statements contained in the notice to be true. When both the parties reside in the same parish or district a single notice is sufficient. The registrar must post up in a conspicuous place at his office a public notice, in the statutory form, of the intended marriage, and must keep it so posted up for seven consecutive days. After these seven days, unless written objections have been lodged and subscribed by the person stating them, the registrar issues a certificate of publication, which is equivalent in effect to banns. As to registration of regular marriages, see REGISTRATION.

Any marriage not celebrated by a minister of religion after proclamation of banns or publication under the Marriage Notice Act, 1878, is, though valid, 'irregular.' 'Clandestine' marriage, in the proper use of the term in Scots law, denotes a marriage with a religious ceremony, celebrated by a layman professing to act as a religious celebrant or by a minister of religion without due proclamation of banns or registrar's certificate of publication. Such a marriage is valid as an irregular marriage; but the celebrant, the parties, and the witnesses are liable in penalties. Other forms of irregular marriage are contracted without any religious ceremony. Such a marriage may be constituted in one of three ways: (1) Marriage *per verba de presenti*. When a man and a woman mutually declare that they take each other there and then as husband and wife a valid marriage is constituted. The interchange of consent makes the marriage. The consent must be mutual, *de presenti*, and unconditional. Where the consent is qualified by a condition, e.g. the subsequent performance of a ceremony, or the birth of a child, or by a reference to a future time, there is no marriage. The consent may be given in any form of words, and either verbally or in writing. (2) Marriage by promise *subsequente copulâ*. Where a woman proves that a man promised to marry her, and that, on the faith of the promise, she allowed him to have sexual intercourse with her, she is entitled to a decree of declarator of marriage. The promise can be proved only by the writ or oath of the defender. The *copula*, following on the faith of the promise of marriage, constitutes marriage; and

accordingly a declarator of such a marriage can be competently brought after the death of one of the spouses. (3) Marriage by cohabitation with habit and repute. Strictly speaking, this is a mode of proving the fact of marriage rather than a mode of contracting marriage. The cohabitation must be at bed and board. The length of time during which the cohabitation has continued must be considerable—a period of years, not of months. The repute of marriage must exist among the neighbours and friends of the parties.

The facility of contracting marriage in Scotland by *de presenti* consent, without the preliminaries requisite to a valid marriage by the law of England, used to be taken advantage of by runaway couples from England, who, crossing the border, contracted marriage by interchange of consent at Gretna Green (q.v.) or elsewhere in Scotland. This practice was checked by an act—known as Lord Brougham's Act—passed in 1856, which provides that no irregular marriage contracted in Scotland by declaration, acknowledgment, or ceremony shall be valid unless one of the parties had, at the date thereof, his or her usual place of residence there, or had lived in Scotland for twenty-one days next preceding such marriage. If this statutory condition as to residence in Scotland has not been implemented, decree of nullity of the marriage can be obtained. The usual method of obtaining registration of an irregular marriage *per verba de presenti* is that introduced by the act of 1856. Under that act the parties may, within three months after the date of the marriage, make a joint application to the sheriff or sheriff-substitute of the county where the marriage was contracted for a warrant to register the marriage. The joint application must be accompanied by a 'Schedule of Particulars,' in the form set out in the Marriage (Scotland) Act, 1916. The statutory schedule is procured from the registrar of the parish or district in which the irregular marriage was contracted, who fills it up according to the information supplied by the parties. The sheriff, on proof that the marriage has been contracted and that one of the parties had lived in Scotland for twenty-one days next preceding the marriage, grants a warrant for the registration of the marriage. The joint application, the schedule of particulars, and the warrant to register, are transmitted by the sheriff-clerk to the registrar of the parish or district in which the marriage was contracted, who must forthwith register it. The application to, and the proceedings before, the sheriff are often believed by the parties to be a civil ceremony of marriage, and, in popular language, spoken of as marriage by or before the sheriff; but the fact is that the parties have married themselves and apply to the sheriff merely to obtain the registration of their marriage. The method of securing registration by the parties appearing before a magistrate or justice of the peace, and being convicted, on their own confession, of having contracted an irregular marriage, has been abolished by the act of 1916. When decree of declarator of a marriage has been obtained the clerk of court is bound to send notice to the registrar.

Marrow is a substance of low specific gravity filling the cells and cavities of the bones of mammals. There are two varieties, which are known

as *red or watery marrow* and *yellow or oily marrow*. In some of the short bones, as the bodies of the vertebrae and the sternum, the marrow has a reddish colour, due to the presence of cells which have this colour and are supposed to be transition forms between the proper marrow cells and red blood-corpuscles. On analysis it is found to contain 75 per cent. of water, the remainder consisting of albuminous and fibrinous matter, with salts and a trace of oil. In the long bones of a healthy adult mammal the marrow occurs as a yellow, oily fluid, contained in vesicles like those of common fat, which are imbedded in the inter-spaces of the medullary membrane—i.e. a highly vascular membrane lining the interior of the bones. This marrow consists of 96 per cent. of oil and 4 of water, connective tissue, and vessels.

Marrow Controversy, one of the most strenuous and memorable struggles in the religious history of Scotland, took its name from a book entitled the *Marrow of Modern Divinity* (1645), written by a Puritan soldier or an illiterate barber. The highly evangelical character of this work, and especially its doctrine of the free grace of God in the redemption of sinners, had made it a great favourite with the few zealous and pious ministers then to be found in the Church of Scotland, and in 1718 an edition was published by the Rev. James Hog of Carnock. A committee of the General Assembly reported against the work as too free in its offer of salvation, and the Assembly formally condemned the book. Twelve ministers, amongst whom were Thomas Boston (q.v.) and the Erskines (q.v.), protested against this decision, and were ultimately rebuked by the Assembly, the national sympathy being on the whole with the 'Representers' or 'Marrow-men.' The controversy was substantially the same that, in 1733, resulted in the deposition of Ebenezer Erskine, and the origination of the 'Secession' body.

Marrum. See REED.

Marryat, FREDERICK, born in Westminster, 10th July 1792, the son of an M.P., in 1806 sailed as midshipman under Lord Cochrane, and spent some years of dangerous service off the French and Spanish coasts and in the Mediterranean. After visiting West Indian waters, he cruised as lieutenant (1812-15) on the north coast of South America, and was twice invalided home. Now a commander, he had command of a sloop cruising off St Helena to guard against the escape of Napoleon (1820-21); he also did good work in suppressing the Channel smugglers, and some hard fighting in Burmese rivers. On his return to England (1826) he was made C.B., and was given the command of the *Ariadne* (1828). He resigned in 1830, and thenceforth led the life of a man of letters. *Frank Mildmay*, his first novel, appeared in 1829, and the *King's Own* in 1830. In 1832-35 he was editor of the *Metropolitan Magazine*, to which he contributed *Newton Forster* (1832), *Peter Simple* (1833), *Jacob Faithful*, *Japhet in Search of a Father*, and *Mr Midshipman Easy* (1834). *Snarleyyow* and *The Pasha of Many Tales* came out in 1836, and in 1837 Marryat set out for a tour through the United States, where he wrote *The Phantom Ship* (1839) and a drama, *The Ocean Waif*. He received £1200 for *Mr Midshipman Easy* and £1600 for his *Diary in America* (1839), but was extravagant and unlucky in his speculations, and at last was deeply embarrassed. *Poor Jack*, *Masterman Ready*, *The Poacher*, and *Percival Keene* appeared before he settled (1843) on his small farm of Langham, Norfolk, where he spent his days in farming and in writing stories for children, including *Settlers in Canada*, *The Mission*, *The Privateer's Man*, and the *Children of the New*

Forest (Valerie was only partly Marryat's; and *Rattlin the Reefer* was written by E. Howard). He died at Langham, 9th August 1848. For improvements in signalling, &c., he had been made F.R.S. (1819) and a member of the Legion of Honour (1833). As a writer of sea-stories of his own particular type Marryat has no superior; his sea-fights, his chases and cutting-out expeditions, are told with irresistible gusto. See the *Life and Letters* by his daughter (1872) and *Life by Hannay* (1889).—The daughter mentioned, FLORENCE (1838–99), successively Mrs Ross Church and Mrs Lean, was born at Brighton, and from 1865 published about eighty novels, besides a drama and many articles in periodicals. She edited *London Society* (1872–76).

Mars (archaic and poetic *Mavors*; in the song of the Arval Brothers, *Marmar*; the Oscan form is *Mamers*), an ancient Italian divinity of war and of husbandry, identified by the Græcising Romans with Ares (q.v.). As the father of Romulus he was specially the progenitor of the Roman race, and he shared with Jupiter the honour of being styled *Pater*, the forms *Marspiter* and *Maspiter* being common for *Mars Pater*. Other titles were *Mars Gradivus*, as the warlike god; *Silvanus*, as the rustic god; and *Quirinus*, from his relation to the state, and his especial care for Roman citizens in their civil capacity as *Quirites*. His priests, the *Salii*, danced in complete armour. The wolf and the woodpecker were sacred to him. He had many temples at Rome, the most celebrated of which were that outside the *Porta Capena*, on the Appian Road, and that of Mars Ultor built by Augustus in the Forum. The *Campus Martius*, where the Romans practised athletic and military exercises, was named in honour of Mars; so was the month of March (*Martius*), the first month of the Roman year. The *Ludi Martiales* were celebrated every year in the circus on 1st August. See PLANETS.

MARS, MADEMOISELLE (ANNE FRANÇOISE HIPOLYTE BOUTET), a great favourite at the Théâtre Français, was born in Paris on 5th February 1779, the illegitimate daughter of an actor Boutet (called Monvel) and an actress Mars Salvétat. She began to act before she was thirteen, joined the Théâtre Français in 1799, and died at Paris on 20th March 1847. She was equally mistress of naïve parts and of those of the coquette, and was especially successful in Molière's masterpieces. Her *Mémoires* were published in 2 vols. in 1849, and her *Confidences* in 3 vols. in 1855.

Marsala, a seaport on the westernmost point of Sicily, 55 miles S.W. of Palermo; pop. 72,500. It is defended by a citadel, has a cathedral and an academy of sciences, and carries on a large trade in wine, the well-known Marsala, which became popular from having been supplied to the British fleet in 1802. It resembles sherry, and is exported to Italy, England, and other countries. Marsala has also a trade in liqueurs, brandy, cheese, macaroni, and sea-salt. The town occupies the site of Lilybæum, the ancient capital of the Carthaginian settlements in Sicily. It obtained its present name from the Saracens, who occupied it in the 9th century, but were driven out by the Normans in the 11th. It was Garibaldi's landing-point for the Sicilian campaign of 1860. The harbour was filled up by the Emperor Charles V. to prevent a Turkish attack; it was reconstructed during the 19th century.

Marschner, HEINRICH (1795–1861), composer, born at Zittau in Saxony, abandoned the study of law at Leipzig for music. He was associated with Weber as opera director at Dresden, and was later kapellmeister at the Leipzig theatre and at the court of Hanover. He composed *Der Vampyr* (1828), *Hans Heiling* (1833), and other operas, &c.

Marseillaise, the stirring song or hymn of the French republicans, was composed, six-sevenths of it (stanza seven of different but uncertain authorship was added some months later), in 1792, by a young officer, Rouget de Lisle (q.v.), then stationed at Strasburg. He composed both words and music under one inspiration on a night in April after dining with the mayor of the city; *Chant de l'Armée du Rhin* was the name he gave it. The song was speedily carried by enthusiastic revolutionists to the chief cities of France. It was brought to Paris by the volunteers of Marseilles, who sang it as they entered the capital (30th July) and when they marched to the storming of the Tuileries. Hence the Parisians called it *La Marseillaise*. Rouget de Lisle's claim to have composed the music has been called in question; but his originality seems proved. Interdicted under the Restoration and the Second Empire, the *Marseillaise* became again the national song on the outbreak of the Franco-German war.

Marseilles (Fr. *Marseille*), in population the second city of France, is the chief town of Bouches-du-Rhône, and is situated on the south coast, about 27 miles E. of the mouth of the Rhone. It is the principal commercial port of France and of the entire Mediterranean. Wheat, oil-seeds, coal, wine, spirits, and beer, sugar, maize, oats, barley, coffee, olive, palm, and cotton oils, pepper, flour, and tallow are the principal imports; clay tiles, wheat, oil-cakes, flour, sugar, oil, wine and spirits, soap, and candles the chief exports. Marseilles is the home port of the Messageries Maritimes, and is served by the P. and O., Générale Transatlantique, and other great shipping companies. The harbour accommodation consists of the old harbour, a natural basin running into the heart of the city; a series of new docks, quays, and warehouses (La Joliette, &c.), giving altogether (including the extensions begun in 1919) about 21 miles of quays; and an outer roadstead between the dams to these docks and a breakwater constructed in deeper water; besides dry-docks, wet-docks, slips, &c. A shipping tunnel (1911–25) with huge bore of 50 feet connects it by way of the Étang de Berre and the Rhone Canal to the great inland waterways of Europe. The industry of the place is very considerable, the first place being taken by soap, vegetable oils, and oil-cake; candles, glycerine, soda, sugar, macaroni, biscuits, iron, lead, zinc, tiles, and leather are manufactured. Marseilles has extensive flour-mills and wine-vaults, and is a centre of the wool trade. There are shipbuilding and engineering yards and a prosperous fishing fleet.

The city of Marseilles is built on the slopes that overlook the old harbour, and at the foot, and has now extended to the south-east. Although greatly improved since 1853, the sanitary condition still leaves something to be desired. Its memorable buildings include the modern Byzantine basilica, which serves as a cathedral; the pilgrimage church, Notre Dame de la Garde, with an image of the Virgin greatly venerated by sailors and fishermen, and with innumerable ex-voto offerings, built in 1864 on the site of a chapel of 1214; the church of St Victor (1200), with subterranean chapel and catacombs of the 11th century; the health office of the port, with fine paintings by Vernet, David, Gérard, and Guérin; the museum of antiquities, in the Château Borély; the Longchamp palace, a very fine Renaissance building (1870), which shelters in one wing the picture-gallery, and in the other the natural history museum; the public library. The public institutions embrace a botanical and a zoological garden, a marine and an astronomical observatory, a faculty of sciences, and schools of medicine, fine arts, Oriental languages, music, commerce, hydrography. Pop. (1861) 260,910;

(1886) 376,143; (1911) 550,619; (1921) 586,341, including a large Italian colony. Marseilles was the birthplace of Pytheas, Petronius, Thiers, and Puget.

One of the oldest towns in France, Marseilles was founded by Phoceans from Asia Minor six hundred years before Christ. It was for many centuries, down to 300 A.D., a centre of Greek civilisation. The Greeks called it *Massalia*, the Romans *Massilia*. As the rival of Carthage it sided with Rome. It supported Pompey against Cæsar, but was taken by the latter in 49 B.C. after an obstinate defence. During subsequent ages it fell into the hands of the Saracens (9th century), Alphonso V. of Aragon (1423), and Henry III. of France (1575). In 1112 it had become a republic; but in 1660 it was deprived by Louis XIV. of the privileges it had enjoyed as a free port almost from its foundation. The years 1720 and 1721 are memorable for the devastations of the plague in the port, when nearly half the population of 100,000 perished, and for the splendid heroism of Bishop Belsunce and the Chevalier Rose. It was the scene of stirring events in 1792 and 1793, and sent large bands to Paris. In 1871 Marseilles, always noted for its extreme republicanism, proclaimed the commune. Its commerce has grown rapidly since the conquest of Algiers and the opening of the Suez Canal.

Marsh, OTHNIEL CHARLES, palæontologist, was born at Lockport, New York, 29th October 1831, graduated at Yale in 1860, and studied further at New Haven and in Germany. He became the first professor of Palæontology at Yale in 1866, and thenceforward devoted himself to the investigation of extinct American vertebrates, of which in various expeditions to the Rocky Mountains he discovered over a thousand new species, some representing wholly new orders. Professor Marsh described many of his discoveries in the *American Journal of Science*, and issued a series of valuable monographs (published by government) on *Odontornithes* (1880), *Dinocerata* (1884); *Sauropoda* (1888), &c. He died 18th March 1899.

Marshal (Fr. *maréchal*; Old High Ger. *marah*, 'a battle-horse,' and *schalh*, 'a servant'), a term meaning originally a groom or manager of the horse, though eventually the king's marshal became one of the principal officers of state. The royal farrier rose in dignity with the increasing importance of the *chevalerie*, till he became, conjointly with the Constable (q.v.), the judge in courts of chivalry. When the king headed his army in feudal times, the assembled troops were inspected by the constable and marshal, who fixed the spot for the encampment of each noble, and examined the number, arms, and condition of his retainers. With these duties was naturally combined the regulation of all matters connected with armorial bearings, standards, and ensigns. In England the earl-marshal is now head of the Herald's College (see HERALD), and the dignity is hereditary in the family of the Duke of Norfolk. In Scotland the office of marischal was hereditary in the family of Keith (q.v.). In 1716 George, tenth Earl Marischal, was attainted in consequence of his share in the rebellion of the previous year, and the office has since been in abeyance. In France the highest military officer is called a marshal, a dignity which originated early in the 13th century. There was at first only one *Maréchal de France*, and there were but two till the time of Francis I. Their number afterwards became unlimited. Napoleon's marshals are celebrated. From the title of this class of general officers the Germans have borrowed their Field-marschal, and the British (since 1736) their Field-marshal (q.v.).

Marshall, capital of Harrison county, Texas, at the junction of three railways, 40 miles W. of Shreveport, Louisiana. It has railway machine-shops, foundries, and a trade in cotton. Pop. 14,000.

Marshall, ALFRED, economist, born in London, 26th July 1842, and educated at Merchant Taylors', and St John's, Cambridge, became a fellow (1865), principal of University College, Bristol (1877), lecturer on political economy at Balliol (1883), and professor of Political Economy at Cambridge (1885-1908) in succession to Fawcett. Of his works, his standard *Principles of Economics* (1890) and its sequels *Industry and Trade* (1919) and *Money, Credit, and Commerce* (1923) are the best known. He died 13th July 1924. See Memoir by J. M. Keynes in *Economic Journal* (Sept. 1924).

Marshall, JOHN, chief-justice of the United States, was born in Fauquier county, Virginia, 24th September 1755, and was studying law when the Revolution began. He served as an officer—for a time under his father, Colonel Thomas Marshall (1730-1802)—from 1775 to 1779; in 1780 he received, while in Richmond, a license to practise law; and in 1781, after a final campaign, he settled down to his profession. He quickly gained distinction, and eventually rose to the head of the Virginia bar. From 1782 he sat in the Virginia legislature; in 1788 he was elected to the state convention, which ultimately—mainly owing to his and Madison's (q.v.) arguments—adopted the new United States constitution. In 1797 he was appointed joint envoy with Pinckney and Gerry (q.v.) to France, where he and Pinckney, as Federalists, were ordered to leave the republic after the envoys had indignantly declined Talleyrand's overtures for a personal and a public loan. His conduct in this matter only made Marshall more respected and popular at home, and in 1799 he was elected to congress; on 12th May 1800 he was appointed secretary of state, which office he held till March 1801. In January 1801 he was appointed chief-justice of the United States, and this position he occupied until his death, at Philadelphia, 6th July 1835. Chief-justice Marshall's long series of important decisions are recognised as standard authority on questions of constitutional law; he it was who secured for the supreme court the decision (in any controversy between the states and the central government) of what is or is not constitutional. It has been said of him that, 'living or dead, he is the supreme court.' He wrote a *Life of Washington*. See *Lives* by Magruder (1885) and Thayer (1901).

Marshall Islands, a group in the western Pacific, bisected by 10° N. lat., and having the Caroline group to the west, consists of two parallel chains of low coral-reefs—one, the Ratak group, consisting of fifteen islands, and measuring in all 48 sq. m.; the other, the Ralik group, eighteen islands, with a total area of 107 sq. m. The coconut and pandanus palms and the bread-fruit tree are the principal sources of food, besides fish. Phosphate and copra are the chief exports. The Micronesian inhabitants, some 12,000 in number, are an ugly but good-natured and hospitable race, fond of song and dance, and skilful weavers of bast mats. The matriarchal rule holds. One Marshall (and Gilbert) explored the islands in 1788. In 1885 they were annexed by Germany, and in 1919 assigned to Japan as mandatory of the League of Nations.

Marshalltown, capital of Marshall county, Iowa, near the Iowa River, 50 miles N.E. of Des Moines, at the crossing of two railways. It has a large trade in wheat, &c., manufactures furnaces, machinery, and much else. Pop. 16,000.

Marshalsea, the jail attached to the Marshalsea Court, originally established under the earl-

marshal of England for the trial of servants of the royal household. Later on it came to be used as a prison for debtors and defaulters, as well as persons convicted of piracy or other offences on the high seas. It stood near the church of St George, Southwark, and existed in the reign of Edward III. It was abolished as the Palace Court in 1849. Bishop Bonner was confined here for nearly ten years, till his death in 1569, and George Wither in 1613.

Marsh-gas. See CARBURETTED HYDROGEN, GAS, METHYL.

Marsh-mallow (*Althæa*), a genus of plants of the natural order Malvaceæ. The species, which are not numerous, are annual and perennial plants, with showy flowers, natives of Europe and Asia. Only one, the Common Marsh-mallow (*A. officinalis*), is an undoubted native of Britain, and is common only in the south, growing in meadows and marshes, especially near the sea. The whole plant is wholesome, abounding in fibre, mucilage, starch, and saccharine matter. It is in the roots chiefly that the mucilage abounds. The emollient and demulcent qualities of marsh-mallow are well known in medicine, and in seasons of scarcity the inhabitants of some eastern countries often have recourse to it as a principal article of food. Lozenges made from it (*Pâtes de Guimauve*) are in use. It is said to be palatable when boiled, and afterwards fried with onions and butter. The Hollyhock (q.v.) is commonly referred to this genus.

Marsh-marigold (*Caltha*), a genus of plants of the natural order Ranunculaceæ, having about five petal-like sepals, but no petals; the fruit

Common Marsh-mallow
(*Althæa officinalis*):
a, a flower; b, fruit.

Marsh-marigold (*Caltha palustris*).

consists of several spreading, compressed, many-seeded follicles. *C. palustris* is a very common

British plant, with kidney-shaped, shining leaves, and large yellow flowers, a principal ornament of wet meadows and the sides of streams in spring. It partakes of the acidity common in the order; but the flower-buds, preserved in vinegar and salt, are said to be a good substitute for capers. It is often called Cowslip in the United States.

Marsilea. See NARDOO, WATER-FERNS.

Marsilio. See FICINO.

Marsivan', a town of Asia Minor, 23 miles NW. of Amasia, with a silver-mine; pop. 15,000.

Marston, JOHN, dramatist and satirist, a son of John Marston, of Gayton (or Heyton), County Salop, by his wife Maria, daughter of Andrew Guarsi, an Italian surgeon, who had settled in London, was born about 1575, probably at Coventry. He matriculated at Brasenose College, Oxford, 4th February 1591-92, and was admitted B.A. 6th February 1593-94. From the elder Marston's will (dated 24th October 1599) it may be gathered that, after adopting the profession of the law, he abandoned it against his father's wish. He married (but the date of his marriage cannot be fixed) Mary, daughter of Rev. William Wilkes, chaplain to James I. and rector of St Martin's, County Wilts. Ben Jonson wittily observed to Drummond of Hawthornden that 'Marston wrote his father-in-law's preachings, and his father-in-law his comedies,' contrasting the asperity of Marston's comedies with the blandness of the chaplain's sermons. With the exception of *The Insatiate Countess* (which is of doubtful authorship), all Marston's plays were published between 1602 and 1607. He gave up play-writing about 1607, but the date at which he entered the church has not been ascertained. In 1616 he was presented to the living of Christ Church, Hampshire, which he resigned in 1631. He died 25th June 1634 in Aldermanbury parish, London, and was buried beside his father in the Temple Church, 'under the stone which hath written on it *Oblivioni Sacrum*.' His widow was buried by his side, 4th July 1657.

Marston's first work was *The Metamorphosis of Pygmalion's Image: and Certain Satires* (1598). Another series of satires, *The Scourge of Villany*, appeared later in the same year, a second edition (with an additional tenth satire) following in 1599. *Pygmalion*, a somewhat licentious poem, may have owed its inspiration to Shakespeare's *Venus and Adonis*. Marston pretends that it was written with the object of bringing discredit on amatory poetry; but the apology cannot be accepted. Archbishop Whitgift condemned it to the flames with other works of a similar tendency. The satires, which were published under the *nom de guerre* of 'William Kinsayder,' are uncouth and obscure. There was a feud between Marston and the satirist Joseph Hall (the future bishop of Norwich), and many hard knocks were dealt on either side. A Cambridge man, one 'W. J.', intervened with his *Whipping of the Satire*, in which he handled Marston roughly; and he was answered, not very effectively, by one of Marston's friends in the anonymous *Whipper of the Satire*. The controversy raged hotly and excited lively interest, but the allusions in these various satirical pieces are not very intelligible to-day.

In September 1599 Henslow records in his *Diary* that he advanced forty shillings to 'Mr Maxtone, the new poete (Mr Mastone),' in part payment for an unnamed play. This 'new poete' was Marston; but there is no other mention of him in the *Diary*. Two gloomy and ill-constructed tragedies, *Antonio and Mellida* and *Antonio's Revenge*, were entered in the Stationers' Register, 24th October 1601, and were published in the following year. They

contain passages of striking power, and a deal of intolerable fustian. In 1604 was published *The Malcontent*, a second edition, augmented by Webster, appearing in the same year. It is more skilfully constructed than the two parts of *Antonio and Mellida*. Marston's command of bold and vivid imagery is effectively displayed in the description of the hermit's cell, iv. 2. He dedicated *The Malcontent* in very cordial terms to Ben Jonson, and in 1605 prefixed some complimentary verses to *Sejanus*. There seem to have been many quarrels and reconciliations between Jonson and Marston. Jonson told Drummond that 'he had many quarrels with Marston, beat him and took his pistol from him, wrote his *Poetaster* on him; the beginning of them were that Marston represented him on the stage in his youth given to venery.' The original quarrel began in or about 1598.

The Dutch Courtesan (1605) is full of life and spirit, the character of the vengeful courtesan Franceschina being drawn with masterly ability. *Eastward Ho* (1605), from which Hogarth is said to have taken the plan of his prints 'The Industrious and Idle Prentices,' was written in conjunction with Chapman and Jonson. It is far more genial than any comedy which Marston wrote single-handed. Some satirical reflections on the Scots were introduced, for which offence the authors were committed to prison at the instance of Sir James Murray, and the report went that their ears were to be cut and their noses slit. *Parasitaster, or the Fawn* (1606), in spite of occasional tediousness, is an attractive comedy; but the tragedy of *Sophonisba* (1606) appals us with its horrors, the description of the witch Erichtho and her cave being gruesome to the last degree. *What You Will*, published in 1607, but probably written some years earlier, has many flings at Ben Jonson. *The Insatiate Countess* was published in 1613 with Marston's name on the title-page, but in a copy (belonging to the Duke of Devonshire) of the 1631 edition the author's name is given as William Barksteed, a poet of some ability and an actor. The rich and graceful poetry scattered through *The Insatiate Countess* is unlike anything that we find in Marston's undoubted works. Probably Marston left the play unfinished when he entered the church, and Barksteed took it in hand. An indifferent anonymous comedy, *Jack Drum's Entertainment*, written about 1600, may be safely assigned to Marston from internal evidence; and he appears to have had some share in another poor play, *Histrionastix*. In 1633 William Sheares, the publisher, issued 1 vol. sm. 8vo, *The Works of Mr John Marston*, comprising the two parts of *Antonio and Mellida*, *Sophonisba*, *What You Will*, *The Fawn*, and *The Dutch Courtesan*. The works were edited by Halliwell (-Phillips) in 1856, 3 vols., and by A. H. Bullen in 1887, 3 vols. The Malone Society in 1922 reprinted the *Antonio* plays from the 1602 quarto (ed. W. W. Greg). Mr G. B. Harrison edited *The Scourge of Villany* (1925).

Marston, JOHN WESTLAND (1820-90), born at Boston, Lincolnshire, early gave up law for literature; and in 1842 his *Patrician's Daughter*, a blank-verse tragedy of the day, was brought out at Drury Lane by Macready. It was the first, and also the most successful, of more than a dozen plays, all Sheridan-Knowlesian, and all forgotten. Besides these, he wrote a novel (1860), a good book on *Our Recent Actors* (1888), and a mass of poetic criticism.—His son, PHILIP BOURKE MARSTON, the blind poet, was born in London, 13th August 1850, and died there on 14th February 1887. His memory will survive through his friendships—with Rossetti, Watts-Dunton, Swinburne, Oliver Madox Brown—rather than through his sonnets and lyrics.

Marston Moor, in the West Riding of Yorkshire, 7 miles W. of York, the scene of a great parliamentary victory, 2d July 1644. The royalist army, about 22,000 strong, was led by Prince Rupert; the parliamentary troops numbered 15,000 foot and 9000 horse, consisting of a Scottish army under the Earl of Leven, a Yorkshire army under Fairfax, and one from the eastern counties under the Earl of Manchester, with Cromwell and Crawford. The battle began about seven o'clock in the evening. On the king's left flank the horse under Goring scattered the forces of Fairfax; on his right the troopers of the fiery Rupert were broken for the first time by Cromwell's 'Ironsides.' Hastily recalling his men from the chase, Cromwell saved the day by supporting Manchester and the Scottish infantry against the king's foot under Newcastle, and routing Goring's horse flushed with their victory. Before nightfall the success was complete, and the king's army fled in utter rout to York, leaving 4000 men dead on the field; among them all Newcastle's 'Whitecoats.' This victory gave the whole north to the Parliament, and first brought into prominence Cromwell's military genius. See S. R. Gardiner's *History of the Civil War* (1886), and Edward Lamplough's *Yorkshire Battles* (1891).

Marsupials, lit. 'pouched animals' (*Marsupialia*, *Didelphia*, or *Metatheria*), a sub-class of mammals, the members of which, except the American opossums and selvas, are now restricted to the Australian and Austro-Malayan regions. They are in many ways simpler than the higher mammals, notably in the structure of the brain and in the absence of a true (allantoic) placenta, except in the case of Perameles. The young are born very helpless, after a short gestation, and are usually stowed away in an external pouch or *marsupium*, where they are fed from the enclosed teats. From the wide occurrence of fragmentary marsupial remains in Triassic and Jurassic strata both in the Old and the New World, it seems that the pouch-bearers have been once widely distributed. Before the stronger mammals which rose up after them they have, however, succumbed, except in the case of the above-mentioned refugees in neotropical forests, and those saved by the insulation of the Australasian regions before any higher mammals gained a foothold. In the retreat thus afforded the marsupials have developed along numerous lines, as it were prophesying the carnivores, insectivores, rodents, and herbivores among the placental mammalia. Thus there are, besides the carnivorous and insectivorous opossums or Didelphyidae (from the United States to Patagonia) and the small selvas or Epanorthidae (South America), six Australasian families—the carnivorous and insectivorous Dasyuridae, the burrowing mole-like Notoryctidae (represented by one remarkable species), the burrowing bandicoots or Peramelidae, the wombats or Phascologyidae with rodent-like teeth, the arboreal Phalangeridae, and the herbivorous terrestrial kangaroos or Macropodidae.

See MAMMALS; also the well-known works of Owen, Huxley, and others on Vertebrates; the relevant parts of Cassell's and the *Standard Natural History*; Chisholm's trans. of Vogt and Specht's *Mammals* (1887); Waterhouse, *Natural History of Mammalia*, i. (1846); and Gould's *Mammals of Australia* (3 vols. 1845-63).

Marsus, DOMITIUS, Latin poet and prose writer of the second half of the 1st century B.C. Though not mentioned (at all events directly) by Horace, he seems to have been a member of Mæcenas's circle, and a friend of Virgil and Tibullus. He wrote *Cicuta*, a collection of epigrams; *De Urbanitate*, a treatise on wit; *Amazonis*, an epic poem; an epitaph on Tibullus; and elegiac poems. Only fragments of his works survive.

Marsyas, a Phrygian satyr, who, having found a flute that played of itself, which Athena had thrown away, was rash enough to challenge Apollo to a musical contest, subject to the condition that the victor should do what he liked to the vanquished. Apollo played upon the cithara, Marsyas upon the flute, and the Muses decided in favour of the god, who punished his rival's temerity by binding him to a tree and flaying him alive. From his blood sprang the river Marsyas; his statue stood in many ancient cities, a monument of the folly of presumption.

Martaban, an ancient town in Burma, on the right bank of the Salwin, opposite to Maulmain. It is reputed to have been built in 576 by the first king of Pegu, and was till 1323 the capital of the kingdom. It was taken by the king of Siam two centuries and a half later, and was twice captured by the British, in 1824 and in 1852. The Gulf of Martaban receives the rivers Irawadi and Salwin.

Martel, CHARLES. See CHARLES MARTEL.

Martello Towers are round towers for coast defence, about 40 feet high, built most solidly, and situated on the beach. They were so called, probably through corruption with Italian *martello*, 'a hammer,' because at Mortella Point in Corsica a small round tower stood admirably an immense cannonade from an English fleet under Lord Hood in 1794. Thereafter, especially in the 18th century, similar towers were erected along the southern and south-eastern coasts of England and of Ireland as a defence against French invasion. They have long been regarded as obsolete.

Marten (*Mustela*), a genus of digitigrade carnivorous quadrupeds of the family Mustelidae, differing from weasels in having an additional false molar on each side above and below, a small tubercle on the inner side of the lower carnivorous cheek-teeth, and the tongue not rough—characters which are regarded as indicating a somewhat less extreme carnivorous propensity. The body is elongated and supple, as in weasels, the legs short, and the toes separate, with sharp long claws; the palms and soles are generally, but not always, furry. The ears are larger than in weasels, and the tail is bushy. The martens exhibit great agility and gracefulness in their movements, and are very expert in climbing trees, among which they generally live. In this genus there are nine or ten species, distributed over Europe, Asia,

in colour with a yellowish throat; the body is about 17 inches long and the tail 8. Its partly arboreal habit is suggested by the common name. See FURS.

Martensen, HANS LASSEN, metropolitan bishop of Denmark and her most prominent theologian in the 19th century, was born at Flensburg on 19th August 1808, and studied at the university of Copenhagen. After shaking off the influence of Grundtvigianism, he became professor of Philosophy at Copenhagen, and in 1845 also court preacher. In 1840 he published a valuable monograph on *Meister Eckhart*, the German mystic, and nine years later his masterly conservative Lutheran *Christian Dogmatics* (Eng. trans. 1866), which gained him in 1854 the primacy of Denmark. This appointment was the cause of a powerful satirical attack upon him by Kierkegaard, and a controversy was aroused in which Martensen suffered severely. His great intellectual energy, however, and the force of his character soon enabled him to recover, and after the publication of another great work, in 3 vols., on *Christian Ethics* (1871-78; Eng. trans. 1873-92), his influence was more dominant than ever. With a mind wonderfully acute and powerful, he was deficient in intellectual sympathy. He stood for many years a bulwark of defence to conservative theology. He died on 3d February 1884. See his *Autobiography*, in Danish (1883), *London Quarterly* (1883), and *Brit. and Foreign Evang. Review*, vol. xxxv.

Martha's Vineyard, an island on the south coast of Massachusetts, 21 miles long, 6 miles in average width. It is noted as a summer resort.

Martial. Marcus Valerius Martialis, one of the finest among the few original Latin poets, and still the first of epigrammatists in verse, was born 1st March 38 or 41 A.D. at Bilbilis in Celtiberian Spain. Bilbilis, apart from its fame as a steel factory, was a centre also of Roman culture, and here Martial received a good education. Coming to Rome, he became in 64 a client of the influential Spanish house of the Senecas, through which he found other patrons, among them L. Calpurnius Piso, the leading man of his day. The tragic failure of the Pisonian plot lost Martial his warmest friends—Lucan, and still more Seneca—from whose heirs, however, he doubtless derived the small wine-growing estate at Nomentum, later prized mainly as a retreat from the bores (or the duns) of Rome. Of his life till Domitian became emperor we know little, except that he never maintained himself by steady professional work, but rather courted imperial and senatorial patronage by his rare social gifts and his genius for *vers de circonstance*. When (80 A.D.) Titus dedicated the Colosseum, Martial's epigrams on the occasion brought him the *jus trium liberorum* and the equestrian rank. Substantial independence, however, he did not obtain from Titus, nor, despite gross and venal flattery, from Domitian. In request as a diner-out, he divided his day between the baths, the theatres, the recitation-halls, and the composition of epigrams, and so far saw his ambition gratified as to count the most distinguished senators of the time among his friends, and all the *literati* in city or province among his readers. His life, however, was not a happy one, being continually shadowed by pecuniary embarrassment; we find him importuning a patron even for a toga or a mantle. By degrees the capital, its cares and its pleasures, became irksome to him; advancing years bereft him of Domitian and his friends of the palace; and the austere Nerva and Trajan had to be conciliated by other and less congenial arts than the adulatory epigram. In a fit of home-sickness he borrowed from his admirer, the

The Pine Marten (*Mustela martes*).

Malaya, and North America. The American 'Pekan' (*M. pennanti*) is the largest species, measuring as much as 46 inches from the snout to the tip of the tail. The most valuable species of marten is the European Sable (*M. zibellina*). It is now generally admitted that there is but one British species, the Pine Marten (*M. martes*), which is rapidly becoming very rare. It is dark brown

younger Pliny, the means of revisiting his ever fondly remembered Bilbilis of simple joys. Here again his good genius found him patrons—among them the highly-cultured Marcella, who presented him with an estate, on which he led an idyllic life. But the *vita municipalis* in the end palled, and we find him fretting for the *vita urbana*—for the Rome he was never again to see. Baulked of his wish to attain his seventy-fifth year, he died, at latest, in 104, aged sixty-three or sixty-six.

Martial possessed, for good and evil, the artistic temperament, its lack of steady purpose, its love of hand-to-mouth independence. This latter he enjoyed by humouring the contemporary vices he could not reform, though, conscience-stricken, he excuses himself on the ground that if his 'page were wanton, his life was honest.' Much of his best work, unfortunately, is his least pure. If, however, we excise 150 epigrams from the 1172 of the first twelve books, his collective writings are free from licentiousness. On the other hand, his genius and skill in verse it were hard to overestimate, his work here being distinguished by its readiness, its fastidious finish, its love of nature, its alternation of masterful eloquence and tremulous pathos. But it is as an epigrammatist, even in its modern and restricted sense, that he remains without a peer. Unequal he often is, but never vulgar. He lifts the veil from the Rome of Domitian, and exposes it mainly on its seamy side with a Hogarthian vividness not outdone by Juvenal himself.

The first noteworthy edition of Martial was that of Friedländer (2 vols. 1886); see also Professor W. M. Lindsay's standard edition of the complete text (in the Oxford Classical Texts, 1902), and his *Martialis Epigrammata Selecta* (1903)—on the latter of which A. E. Street based his admirable *Hundred Select Epigrams Metrically Rendered* (1907)—and Courthope's translations and imitations (1914).

Martial Law is the exercise of arbitrary power by the supreme authority in a district or country where the ordinary administration has ceased to be operative, either on account of civil disturbance or because of the presence therein of a hostile force, though, in the latter case, the 'Laws of War' would be a better term. Martial law is often confounded with military law, because in war or riot the supreme authority may have recourse to courts-martial and troops to maintain order. Military Law is summed up in the Army Act, 1881 (see **MUTINY ACT**), the Territorial and Reserve Forces Act of 1907, and rules, regulations, and royal warrants issued in accordance therewith. Accordingly it governs the soldier at all times, but affects civilians only when accompanying a force on active service; while martial law has been defined as 'no law,' but simply the will of the supreme authority. It is not recognised by British jurisprudence, and no rules are laid down for its application. It is assumed that, when the ordinary civil tribunals fail, the supreme authority will do his best to maintain order. He may therefore, if he thinks right, announce his intention of treating the civil population as though under military law, or in any other way that commends itself to him; but if they are British subjects he will have afterwards to justify his action by showing that it was absolutely necessary, and so obtain an indemnity from parliament for conduct which is in itself illegal. Military tribunals have several times been given power by Act of Parliament to try offenders against the public peace in Ireland, as in 1798, but here also Acts of Indemnity have always followed.

On the Continent the practice is different, and when necessary a 'state of siege' is proclaimed in the disturbed district or occupied territory, and the

inhabitants are thereby brought to a certain extent under military law.

Martigny, or **MARTINACH** (the *Octodurus* of the Romans), three united hamlets in the Swiss canton of Valais, is situated on the Simplon railway, 24 miles SE. of the Lake of Geneva. Two noted routes, one to the vale of Chamouni by the Tête Noire or the Col de Balme, the other over the Great St Bernard to Aosta, branch off here. Pop. 4000.

Martignes, a town in the French department of Bouches-du-Rhône, is situated on several islands, united by bridges, at the entrance to the Étang de Berre, 20 miles NW. of Marseilles. From its position it has been called the Provençal Venice. Pop. 6000, chiefly engaged in catching and curing fish, and in shipbuilding.

Martin. See **SWALLOW**.

Martin, the name of five popes, of whom the fourth and fifth are most noteworthy.—**MARTIN IV.**, a native of Brie in Touraine, was born about 1210, made cardinal in 1261, and elected pope in 1281. He was a mere tool of Charles of Anjou, and degraded himself even by employing the weapons of spiritual censure in his behalf. But all his efforts to buttress the French power in Sicily proved futile, and three years after the atrocity of the Sicilian Vespers he died, 1285.—**MARTIN V.** must be noticed as the pontiff in whose election was finally extinguished the great Western Schism (see **ANTIPOPE**, **CHURCH HISTORY**). He was originally named Otto di Colonna, of the great Roman family of that name. On the deposition of John XXIII., and the two rival popes Gregory XII. and Benedict XIII., in the Council of Constance, Cardinal Colonna was elected (1417). He presided in all the subsequent sessions of the council, and the fathers having separated without discussing the questions of reform, at that period earnestly called for in the church, Martin undertook to call a new council for the purpose. It was summoned to meet at Siena, and ultimately assembled at Basel in 1431, but the pope died suddenly just after its opening.

Martin, **St.** Bishop of Tours, was born at Sabaria in Pannonia about the year 316. He was educated at Pavia, and at the desire of his father, who was a military tribune, entered the army, first under Constantine, and afterwards under Julian the Apostate. The virtues of his life as a soldier are the theme of more than one interesting legend. On obtaining his discharge from military service, Martin became a disciple of Hilary of Poitiers. He returned to his native Pannonia, and converted his mother to Christianity, but he himself endured much persecution from the Arian party, who were at that time dominant; and in consequence of the firmness of his orthodoxy, he is the first confessor, rather than martyr, honoured in the Latin Church with an office and a feast. On his return to Gaul about 360 he founded a convent of monks near Poitiers, where he himself led a life of great austerity and seclusion; but in 371 he was drawn by force from his retreat, and made Bishop of Tours. The fame of his sanctity, and his reputation as a worker of miracles, attracted crowds of visitants from all parts of Gaul; and in order to avoid the distraction of their importunity, he established the monastery of Marmoutier near Tours, in which he himself resided. He died between 397 and 401, and St Ninian, who had visited him at Tours and ever preserved the greatest veneration for him, dedicated to his memory the church he was then building at Whithorn in Galloway. His life by his contemporary, Sulpicius Severus, is a very curious specimen of the Christian literature of the

age; it is practically the only source for his life, but is full of legendary matter and chronological errors. Martin left no writings, the short *Confession of Faith on the Holy Trinity* being more safely regarded as spurious. In the Roman Catholic Church the festival of his birth is celebrated on the 11th November. In Scotland this day still marks the winter-term, which is called *Martinmas*. Formerly people used to begin St Martin's Day with feasting and drinking; hence the French expressions *martiner* and *faire la St Martin*, 'to feast,' and the fact that St Martin is the patron of drinking and of reformed drunkards.

See the books by Reinkens (Gera, 3d ed. 1876), Charnard (Poitiers, 1873), Cazenove's *St Hilary and St Martin* (1883), and Scullard's *Martin of Tours* (1891).

Martin, BON LOUIS HENRI, a great French historian, was born at Saint-Quentin, 20th February 1810, and educated for a notary, but already at twenty had determined for a literary career. His first book was an historical romance, *Wolfthurn* (1830), followed by three others treating of the period of the Fronde. He next joined Paul Lacroix, the 'Bibliophile Jacob,' in his vast project for a history of France in 48 volumes, consisting of extracts from histories and chronicles from the earliest period to 1830. He published the first volume in 1833, and henceforward toiled alone at the vast undertaking, which was completed on a smaller scale in 1836. He now set himself to a still more gigantic task, his great *Histoire de France* (15 vols. 1833-36). A third and much improved edition (19 vols. 1837-54) earned the Gobert prize; the fourth edition (17 vols. 1855-60) was awarded by the Institute in 1869 the great prize of 20,000 francs. This magnificent work comes down only to 1789; its continuation to the author's own time formed the less admirable *Histoire de France Moderne* (2d ed. 5 vols. 1878-85). Martin was chosen deputy for Aisne in 1871, senator in 1876. He was elected a member of the French Academy in 1878. He wrote several minor histories, such as the *Histoire de Soissons* (1837), *Daniel Manin* (1859), *Jeanne d'Arc* (1872); and died at Paris, 14th December 1883. As a historian Martin was of the school of Thierry. As sensitive to the romantic as Michelet, he kept his imagination in check by the weight of his learning, the solidity of his sense, and by due respect to documents; an exception is his reconstruction of a history of Gaul; even so his work here gave a great stimulus to Celtic and anthropological studies. As a whole, his history is excellently arranged and admirably written, and, if prejudiced at points, is beyond doubt the best work dealing in detail with the history of France in its entirety.

See the *Life* by Hanotaux (1885), Mulot's *Souvenirs Intimes* (1885), and Jules Simon's *Mignet, Michelet, Henri Martin* (1889).

Martin, JOHN, painter, was born at Haydon Bridge, near Hexham, Northumberland, 19th July 1789. In 1806 he went up to London, in 1808 married, and, after a struggling youth as an heraldic and enamel painter, in 1812 exhibited 'Sadak in search of the Waters of Oblivion' at the Royal Academy, with which body he soon afterwards quarrelled. It was the first of his sixteen 'sublime' works, whose 'immeasurable spaces, innumerable multitudes, and gorgeous prodigies of architecture and landscape' divided the suffrage of the many between Martin and Turner; Bulwer-Lytton indeed pronounced him 'more original, more self-dependent' than Raphael and Michelangelo. Even yet the memory of the sixteen works is kept lurid by the coloured engravings of the 'Fall of Babylon' (1819), 'Belshazzar's Feast' (1821), 'The Deluge' (1826), &c. Martin also busied himself with projects for the improve-

ment of London. He died at Douglas, Isle of Man, 17th February 1854. See study by Mary Pendered (1923).

Martin, RICHARD, known as 'Humanity Martin' and 'Humanity Dick,' was born in Dublin of an old Irish landed family in February 1754, and educated at Harrow and at Trinity College, Cambridge. In 1776-83 and 1798-1800 he sat in the Irish parliament, and in 1801-26, after the Union, in the parliament of the United Kingdom; in 1781 he had been called to the Irish bar. In 1822 he carried the first legislation in any country for the protection of animals (3 Geo. IV. chap. 71), and in 1824 was one of the founders of the Royal Society for the Prevention of Cruelty to Animals. He laboured also, though unsuccessfully, to abolish the death penalty for forgery, and to secure counsel for prisoners charged with capital crimes. The number of his duels was notorious. He died at Boulogne, 6th January 1834.

Martin, SIR THEODORE, born in Edinburgh in 1816, was educated there at the High School and university, and, in 1846 settling in London, became a prosperous parliamentary solicitor. Among his earliest writings were the well-known 'Bon Gaultier' ballads, written in conjunction with Professor Aytoun. This was followed by translations of Goethe's *Poems and Ballads*, Henrik Hertz's *King René's Daughter*, and Oehlenschläger's *Corregio and Aladdin or the Wonderful Lamp*. Further metrical translations were of Horace's *Odes* (1860), of his whole works (1882), Catullus (1861), the *Vita Nuova* of Dante (1862), *Faust* (i. and ii. 1865-86), Heine (1878), the *Aeneid* (i.-vi. 1896), and Leopardi (1904). In 1863 he issued a volume of original and translated poems, and in 1870 an admirable little book on Horace. He wrote lives of Aytoun (1867), the Prince Consort (5 vols. 1874-80), Lord Lyndhurst (1883), and the Princess Alice (1885). He died 18th August 1909.

LADY MARTIN, well known as an actress by her maiden name, Helen Faucit, was born 11th October 1820, and made her début as Julia in the *Hunchback* at Covent Garden in January 1836. She was at once successful, took a leading part in Macready's Shakespearian revivals, in the first representation of Lytton's plays, and in Browning's *Blot in the 'Scutcheon* and *Strafford*. As an interpreter of Shakespeare's heroines she stood first among the actresses of her time. After her marriage to Theodore Martin in 1851 she left the stage, appearing only at rare intervals for public or charitable purposes, as in Beatrice at the opening of the Shakespeare Memorial Theatre at Stratford. In 1885 she published *On Some of Shakespeare's Female Characters*. She died 31st October 1898. See the *Life* (1900) by her husband.

Martina Franca, a conspicuous hill-town of Southern Italy, half-way between Taranto and Monopoli. It is a thriving place, with quarries and a trade in oil, and there is a large palace of the former dukes. Pop. 30,000.

Martineau, HARRIET (1802-76), born at Norwich, was the daughter of Thomas Martineau, a Norwich manufacturer. In 1830 she wrote *Traditions of Palestine*, and gained three prizes for three *Theological Essays* for the Unitarian Association. In 1831 she resolved to bring out a series of stories as *Illustrations of Political Economy*, convinced that the work was wanted. Notwithstanding repeated refusals and discouragements from publishers she persevered in her plan, and in 1832 the first number appeared. A fortnight after publication the demand for this number reached five thousand, and from that day the way was open to her for life, and she never had

any other anxiety about employment than what to choose, nor any real care about money. Her popularity was extraordinary during the appearance of *Illustrations of Political Economy*. She removed to London in 1832, the better to carry on her work. In 1834 she went to America for two years, and after her return published *Society in America* (1837) and a novel, *Deerbrook*, in 1839. She went abroad the same year, returned ill, and settled at Tynemouth, where she remained, a complete invalid, till 1844. During her illness she wrote *The Hour and the Man*, four volumes of children's tales, and *Life in the Sick-room*. She recovered through mesmerism, left Tynemouth, and fixed her abode in the Lake Country, where in 1845 she built herself a house near Ambleside. The same year she published *Forest and Game-law Tales*. In 1846 she visited Egypt and Palestine, and on her return issued *Eastern Life*. In 1849 she completed Knight's *History of the Thirty Years' Peace*; in 1851, with H. G. Atkinson, she published *Letters on the Laws of Man's Social Nature and Development*, showing that her unitarianism had been superseded by agnosticism; in 1853 she translated and condensed Comte's *Philosophie Positive*. Her *Autobiography*, printed many years before her death, was published with an editorial volume in 1877. See *Life* by Florence F. Miller (1884), Morley's *Critical Miscellanies* (iii. 1909), and Walford's *Twelve English Authoresses* (1892).

Martineau, JAMES, theologian, brother of the preceding, born at Norwich, 21st April 1805, was educated at the grammar-school there, and under Dr Lant Carpenter at Bristol; and having given up the idea of becoming a civil engineer, entered the Unitarian Manchester College (then at York) to qualify (1822-26) for the ministry. He had been thirteen years a distinguished Unitarian minister at Dublin and Liverpool when, in 1841, he was appointed professor of Mental and Moral Philosophy at Manchester New College. He removed to London in 1857 after that institution had been transferred thither, becoming also one of the pastors in Little Portland Street Chapel; and he was principal of the college from 1869 till his retirement in 1885. Martineau was recognised for fifty years as one of the profoundest thinkers and most effective writers of his day. Earnest and lofty in his aims, and catholic in his sympathies, he united strong grasp of thought and power of subtle analysis to a rare mastery of English style. Unlike the older Unitarian school, who professed to accept unquestioningly whatever was in the Bible, he insisted that the last appeal must be to the human mind, heart, and conscience. He was a powerful and persuasive preacher; and it was his *Endeavour after the Christian Life* that secured an attentive hearing for all his later work. In a 'second education' under Trendelenburg at Berlin in 1848, he broke finally with determinism and utilitarianism. Like Channing, he revolted from the school of Priestley, and became a spiritual teacher in the apostolical succession of Butler and Kant; over against Newman he was one of the most typical representatives of religious thought in his generation; and in philosophy, representing the 'intuitionist' school and strenuously vindicating a lofty sphere for conscience and the ethical will, he was a power to be named alongside of T. H. Green. From 1869 till 1880 he was one of the most prominent members of the famous Metaphysical Society, which included men so diverse as Stanley, Fronde, Huxley, Lubbock, Clifford, Gladstone, and Manning. He died 11th January 1900 revered by Christians of all denominations as a great apostle of Christian Theism.

His *Life and Letters* were published by Drummond and Upton (2 vols. 1902); a 'biography and study' by

A. W. Jackson (1900); *Recollections* by A. H. Craufurd (1903); and a compact 'study of his life thought' by J. E. Carpenter (1905).

Martínez Ruiz, JOSÉ, Spanish prose writer, better known by his pseudonym of AZORÍN, was born at Monovar in 1876. He established his reputation with three novels, *La Voluntad* (1902), *Antonio Azorín* (1903), *Las Confesiones de un pequeño filósofo* (1904), the last considered best, but later abandoned this form for work in literary criticism, as *Lecturas españolas* (1912), *Al margen de los Clásicos* (1915), *Los dos Luises y otros ensayos* (1921), and for imaginative essays of the past, as *Castilla* (1921). He is the chief representative of a reaction against the naturalism of Pardo Bazán and Ibáñez, and in Flaubert and the Spanish classics is to be found the main source of his inspiration. A charming delicacy is the most striking quality of his style, and in his use of Arabic terms and his revival of old words he has enlarged the Spanish vocabulary and given a new harmony to modern Spanish; in his device of short sentences, in his avoidance of diminutives, and in other peculiarities of style, some might claim to find, however, a departure from the genius of the language.

Martinique, one of the French West India Islands, 43 miles long, with an area of 380 sq. m., and 244,000 inhabitants, mostly of mixed race, was colonised by France in 1635. St Pierre (q.v.) was the principal commercial place, but now it is Fort-de-France (26,000), the capital. Sugar is the staple crop. The exports are mainly sugar, molasses, rum, and cocoa. Slavery was abolished in 1848; labour is largely performed by coolies. The island is volcanic, like St Vincent (q.v.) and other adjacent islands. There was a bad eruption in 1812, and in May 1902 Mont Pelée, a volcano quiescent for fifty years, burst into violent eruption; a whirlwind of incandescent gases charged with red-hot particles rushed down on the city, set the houses on fire, and burnt even the ships in the harbour, destroying St Pierre with all its inhabitants almost instantly, devastating over half the island, and strewing volcanic ashes over tens of thousands of square miles. Minor disturbances took place in the succeeding months, and a second destructive explosion followed in August.

Martímas, a Scottish term-day (11th Nov.). See MARTIN (ST.), TERM.

Martinsburg, capital of Berkeley county, West Virginia, in the Shenandoah Valley, 114 miles by rail W. of Baltimore. It is in the heart of a limestone and fruit-growing country, and there are lime and canning works; also hosiery, woollen, and clothing factories. Pop. 13,000.

Martin's Ferry, a city of Ohio, on the Ohio River, 50 miles SW. of Pittsburgh. The surrounding region is rich in coal, and there are glass, iron, tin, and engineering works. Pop. 12,000.

Martos, a town of Andalusia, Spain, 16 miles SW. of Jaén, on a steep hill crowned by an old castle. It has mineral baths, and trades in olive oil. Pop. 20,000.

Martyn, HENRY, missionary, was born at Truro, 18th February 1781, and educated at Truro grammar-school and St John's College, Cambridge. He was senior wrangler and first Smith's prizeman in 1801, and next year became fellow of his college. Charles Simeon's influence turned him from law to missions, and in 1805 he sailed for India as a chaplain under the Company. He was stationed successively near Serampore, at Dinapore, and at Cawnpore, and from the beginning, in spite of ill-health, gave himself eagerly to the study of the native languages. He translated the New Testament into Hindustani, Hindi, and Persian, the

Prayer-book into Hindustani, and the Psalms into Persian; he next travelled to Bushire, Shiraz, Tabriz, Erivan, Kars, Erzerum, and Tokat, where he sank exhausted by fever, 6th October 1812. See his *Journals and Letters* (ed. Wilberforce, 1837), and *Lives* by Sargent (1819, and many editions) and G. Smith (1892).

Martyr (Gr. *mártus*, *mártur*, 'a witness'), the name given in ecclesiastical history to those who, by their fearless profession of Christian truth, and especially by their fortitude in submitting to death itself rather than abandon their faith, bore the 'witness' of their blood to its superhuman origin. Of the same use of the word there are some examples also in the New Testament, as in Acts, xxii. 20; Rev. ii. 13; xvii. 6. But this meaning, as its technical and established signification, is derived mainly from ecclesiastical writers. During the persecutions of the Christians in the first three centuries (see CHURCH HISTORY), contemporary writers, as well pagan as Christian, record that many Christians, preferring death to apostasy, became martyrs or witnesses in blood to the faith, often in circumstances of the utmost heroism. The courage and constancy of the sufferers won the highest admiration from the brethren. It was held a special privilege to receive the martyr's benediction, to kiss his chains, to visit him in prison, or to converse with him; and a practice arose by which the martyrs gave to sinners who were undergoing a course of public penance letters of commendation to their bishop (see INDULGENCE). The day of martyrdom, moreover, as being held to be the day of the martyr's entering into eternal life, was called the *natal* or *birth* day, and as such was celebrated with peculiar honour, and with special religious services. Their bodies, clothes, books, and the other objects which they had possessed were honoured as Relics (q.v.), and their tombs were visited for the purpose of asking their intercession (see CANONISATION). Cyprian says of catechumens who died before baptism, that they had been baptised 'with the most glorious baptism of blood'; and the blood-baptism was held to remit sin and the temporal penalty of sin also. The number of martyrs who suffered death during the first ages of Christianity has been a subject of great controversy. The ecclesiastical writers, with the natural pride of partisanship, have, it can hardly be doubted, leaned to the side of exaggeration. Some of their statements are palpably excessive; and Gibbon, in his well-known 16th chapter, throws great doubt even on the most moderate of the computations of the church historians. But it is clearly though briefly shown by Guizot, in his notes on this celebrated chapter, that Gibbon's criticisms are founded on unfair and partial data, and that even the very authorities on which he relies demonstrate the fallaciousness of his conclusions. The first recorded martyr of Christianity, called the 'protomartyr,' was Stephen, whose death is recorded in Acts, vi. and vii. The protomartyr of Britain was Alban of Verulam, who suffered under Diocletian in 286 or 303.

MARTYROLOGY, a list of the commemoration days of Christian martyrs, generally with some account of their life and death, arranged in the order of months and days, and intended partly to be read in the public services of the church, partly for the guidance of the faithful in their devotions. The use of the martyrology is common to both the Latin and the Greek Church; in the latter it is called *menology*, or 'month-calendar.' Nearly all the later Western martyrologies are based upon one or other of three works, the Hieronymian, the Lesser Roman, and Bede's Martyrology. The first, which was stated to be compiled by St

Jerome from records of martyrdoms collected by Eusebius, is itself a compilation from numerous earlier calendars, and contains notices of many facts long subsequent to Jerome's time. A copy of the Lesser Roman Martyrology was discovered at Ravenna by Ado, Archbishop of Vienne, in 850, and seems to have been rather a private historical calendar than one intended for public use. The independent compilation by Bede has come down to us only in later editions, chiefly of the 9th century, as that of Florus of Lyons, Hrabanus Maurus, Ado of Vienne, and Usuard of Paris, as well as that of Notker of St Gall (912). The best-known *menology*, that compiled by order of the Emperor Basil, the Macedonian, in the 9th century, was edited in 1727 by Cardinal Urbini. In 1866 Professor W. Wright published a Syriac martyrology discovered by him, and written in or before 412. The official 'Roman Martyrology,' designed for the entire church, was published by authority of Gregory XIII., with a critical commentary, by Baronius in 1586; an enlarged edition of the same was issued by Rosweyd in 1613. See Achelis, *Die Martyrologien: ihre Geschichte und ihr Wert* (1900).

Martyr, PETER. See PETER.

Marut is, in Hindu Mythology, the god of wind. See INDIA (*The Vedas*).

Marvell, ANDREW, was born on the 31st March 1621 at Winestead, Holderness, of which his father, Andrew Marvell, was rector. The family removed to the outskirts of Hull in 1624 when the elder Marvell became lecturer at Holy Trinity and master of the Charterhouse. From the grammar-school Marvell went, probably in 1633, to Trinity College, Cambridge. To the *Musa Cantabrigiensis* in 1637 he contributed two poems addressed to Charles I., one in Greek and one in Latin. A scholar of his college in April 1638, and B.A. about a year later, he was, it is said, induced by Jesuits to leave the university, found by his father in a London bookseller's shop, and brought back. In 1640-41 his father, from whom he seems to have inherited his genius and nobility of character, was drowned in the Humber; and about this time Marvell left the university—for a clerkship in a Hull office, says tradition. In 1642-46 Marvell travelled in Holland, France, Italy, and Spain. In Rome he did not meet Milton, as is sometimes said, but he did meet the poetaster Richard Flecknoe, whose name was to be used as a stalking-horse by Dryden in his *MacFlecknoe*, and he bantered him in a satire somewhat after Donne's manner, but more good-humoured and humorous. The same qualities, with perhaps more brilliant wit, appear in the satirical 'Character of Holland,' which seems to date from 1652-3. In 1650 Marvell became tutor to Mary Fairfax, daughter of the Parliamentary general. To the time spent at Nun Appleton, Fairfax's Yorkshire seat, are assigned not only the poems 'Appleton House' and 'Upon the Hill and Grove at Billborow,' but the pastorals and 'Mower Songs'; and, above all, those garden poems on which his fame as a nature poet chiefly rests. Milton fixed upon Marvell as a man fit to assist him in his office of Latin secretary to Cromwell, and recommended him to Bradshaw in a letter of February 1652-3. The recommendation was not acted upon till 1657. In the meantime Marvell became tutor to Cromwell's ward, William Dutton, at Eton, where he had the society of John Hales and of a former Bermuda minister, who may have suggested the writing of 'Where the remote Bermudas ride'; and he corresponded with Milton and Cromwell. Among his poems of this period are the magnificent 'Horatian Ode upon Cromwell's Return from Ireland' and others glowing with admiration for Cromwell's character

and work. Unlike some who joined with him in deploring the Protector's death, and recanted when the Stewarts returned, Marvell praised him in his latest writings. He continued in office under Richard Cromwell. In January 1658-9 he was elected, perhaps by corrupt practices, member of parliament for Hull, which he represented uninterruptedly till his death. He received 6s. 8d. a day during session from his constituents. Except when unknown business, probably private, withdrew him to Holland, and when, in 1663-65, with permission of the House and consent of his constituents, he was secretary to the Earl of Carlisle on his embassy to Muscovy, Sweden, and Denmark, he gave assiduous attention to the work of parliament. About a year and a half before his death he apologised for the abruptness of his speech, as he was unaccustomed to speak there; but in hundreds of letters he kept his constituents informed of the course of events; and his moral weight seems to have been felt. There is good reason to believe that he exerted himself in parliament to secure Milton's safety after the Restoration. On the whole, however, a man of Marvell's character and views could do little in the Cavalier Parliament. He was better able to fight for liberty of conscience and against misgovernment by writing than by speaking; and he was more outspoken in anonymous verse-satires, which were handed about in manuscript, than in his printed prose, or in letters which, as he says himself, were apt to be tampered with. His prose works include *The Rehearsal Transposed* (1672-3), a triumphantly witty reply to Samuel Parker's writings on 'the mischiefs and inconveniences of Toleration'; *Mr Smirke, or the Divine in Mode* (1676), a work of like nature; and *An Account of the Growth of Popery and Arbitrary Government* (1677). For the discovery of the author of the last-named, which was anonymous, a reward was offered. Marvell's life was believed to be in danger, and there were suspicions of poisoning when, 'ex ignorantia medicis senis atque superciliosi,' he died on the 18th August 1678. His political position has been variously judged. Some, looking especially to his indignation against the historian of the Long Parliament in 'The Death of Tom May,' and the famous passage in praise of Charles I. in the 'Horatian Ode,' hold that at first, if not throughout his life, he was a Royalist. There are difficulties to be explained away on any theory; but bearing in mind that Marvell elsewhere shows himself capable of magnanimous appreciation of an enemy's good qualities, and scorn of self-seeking in partisans of his own side, one receives from a chronological reading of his works the impression that he was not a political theorist. At the Restoration he was willing to accept monarchy rather than suspend the function of government in the hope of improving the machine. He did what he could to secure a fair chance for Charles II. Gradually he became more and more republican, each turn of the screw being given by experience rather than by logic. At last he became convinced that the Stewarts must go, and his last satires are a call to arms against monarchy. 'Nevertheless,' he says in *The Growth of Popery*, 'because mankind must be governed some way and be held up to one law or other, either of Christ's or their own making, the vigour of such humane constitutions is to be preserved untill the same authority shall revoke them.' All his verse after the Restoration is satirical, partly in popular ballad forms of great vigour, partly in heroic couplets. His prose works are models of incisive irony. Their humour, magnanimity, and honesty were fatal to the quibbling polemics to which they were replies. But Marvell is best remembered as a poet

of nature, and perhaps the greatest master in English of the eight-syllable couplet. He came into a world of poetry dominated by Donne, to whom in imaginative insight he is allied. His poetry is by no means free from conceits, for notwithstanding his delicacy and grace his taste was fallible; but his conceits offend less than those of the other poets of the metaphysical school, and his intense sincerity often burns them out altogether. He was Milton's understudy in more than his official duties.

Little of Marvell's verse was printed in his lifetime. His widow, of whom nothing is known, published his *Miscellaneous Poems* in 1681; and his satires, with many spurious, were included in the *Poems on Affairs of State* (1689). His works were edited by Dr Grosart (4 vols. 1872-75), his poems and satires by G. A. Aitken (1892), with a valuable bibliography, &c., and by an anonymous editor (1923). Professor Margoliouth has undertaken a complete edition of Marvell, including his letters. See also Birrell, *Andrew Marvell* (1905); Poscher, *Andrew Marvells Poetische Werke* (1908); *Andrew Marvell: Tercentenary Tributes*, ed. W. H. Baggeley (1922); H. M. Margoliouth (1922) and Pierre Legouis (1923) in *Mod. Lang. Rev.*

Márwár. See JODHPUR.

Marx, KARL, the founder of international socialism, was born at Trèves, 5th May 1818. His father was a lawyer in that town, and the young Marx was sent to the universities of Bonn and Berlin to study with a view to the same profession; but he seems really to have devoted his time to history and philosophy. He was apparently a disciple of Hegel, and he had for a time the intention to settle at Bonn as a lecturer on philosophy. Marx, however, soon gave up the idea of following an academic career, and in 1842 undertook the editorship of the democratic organ, the *Rhenish Gazette*. His experience on the journal convinced him that his economic knowledge required enlarging; and after his marriage he proceeded in 1843 to Paris, the headquarters of revolutionary economics. In the *Deutsch-Französische Jahrbücher* he began that course of literary activity which, varied by agitation, constituted the work of his life. Expelled from France in 1845, he settled in Brussels, where amongst other productions he wrote his attack on Proudhon's *Philosophie de la Misère*, entitled *Misère de la Philosophie*.

But his chief work at Brussels was the reorganising, along with Fr. Engels, of the Communist League, for which he wrote the famous *Manifesto* (see SOCIALISM). In 1848 Marx took an active part in the revolutionary movement on the Rhine, and after its failure finally settled in London in 1849. Here at the British Museum he acquired his marvellous knowledge of economic literature and of the economic development of modern Europe. The early fruits of his labour appeared in a work, *Zur Kritik der politischen Oekonomie* (1859), the theories of which were, however, carried forward into the first volume of his *Kapital* (1867). Before that year Marx had, in 1864, resumed his work as agitator. He had the foremost part in founding and directing the International, and after the death of Lassalle he won practical control of the social-democratic movement in Germany. He died in London, 14th March 1883.

Marx's works leave us in no doubt that he was a man of extraordinary knowledge, which he handled with masterly skill. To one who has taken the pains to understand his terminology his style is lucid and powerful, though also sometimes tedious owing to the minuteness of his exposition; and the march of thought is varied by humour, unsparing invective, and flashes of light from the most unexpected quarters. Since the beginning of literature few books have been written like the

first volume of Marx's *Kapital*. It is premature to offer any definitive judgment on his work as revolutionary thinker and agitator, because that is still very far from completion. There need, however, be no hesitation in saying that he, incomparably more than any other man, has influenced the labour movement all over the civilised world; his theories have in a thousand ways already penetrated the different strata of society, even the highest, but most of all the working-classes. It may also be safely said that his views can have any hope of realisation only after very extensive modification. In many respects his analysis of the economic development of modern society has been justified by subsequent events, but in many also it has been falsified; and it could be shown that he has left out of account some of the decisive factors in social development.

As he tells us in the preface to the *Kapital*, the final aim of his great work is to reveal the economic law that moves modern society. The social development of modern times depends on capital; the cardinal fact in modern history is the rise, culmination, and final catastrophe of capitalism. But the full development of capital and of the class representing it involves the rise of socialism and of the proletariat. The great work of Marx, therefore, gives us an historical analysis of capital and by implication a forecast of socialism.

The development of capitalism depends on the appropriation and accumulation of surplus value; we cannot understand the nature of capitalism without understanding surplus value. With the analysis of value, therefore, the great work of Marx begins. The wealth of modern society, in which the capitalistic method of production prevails, appears as an enormous collection of commodities, which are exchanged one against another in the utmost variety of ways. But they have one common characteristic: they are products of human labour. The value of all the commodities that circulate in the world-market is constituted by human labour, and measured in human labour-time; not this or that individual labour, but the average labour of the community, under the normal social conditions of production, with the average degree of skill and intensity of labour.

But labour cannot be carried on without the means of labour, which are land and capital. Taking England as the classic example of the fully-developed capitalism, Marx shows that since medieval times the course of historic evolution has tended to render the instruments of labour the monopoly of a special class. It is clear that the rise of such a class has had as complement the rise of another class who are destitute of the means of production, but who being free may sell their labour at the wage it can obtain in the market. They accordingly sell their labour for a wage, which represents the average subsistence necessary for themselves and the children required to continue the supply of labour. Their labour, however, when utilised by the capitalist produces a value greater than their wage. This is the *surplus value* of Karl Marx. The growth of capitalism depends on the appropriation and accumulation of this surplus value; and the history of modern society is a history of the antagonism of the two classes concerned—of the capitalist class, who absorb surplus value, and of the proletariat, who produce it.

The progress of the conflict leads to many remarkable results. On the one hand the great capitalist goes on destroying the smaller, until the wealth of the world is concentrated in the hands of a few colossal capitalists. On the other hand the development of the capitalistic system causes degradation, demoralisation, misery, and pauper-

ism among the labouring classes, but it at the same time organises them in industrial armies; above all it raises them to a clear consciousness of their class position. In this way the process goes on in obedience to its own inherent laws, wealth accumulating at one pole of society and wretchedness at the other. Capitalism is at last ruined by an excess of the sustenance on which it grew—viz. surplus value. When things have become intolerable, the organised proletariat take the initiative, and seizing possession of the means of production carry on the economic process for the good of all. Government—which has always hitherto been an arrangement for keeping the producing classes in subjection—will simply become a control of productive processes.

As understood by Marx, socialism does not propound utopian schemes, nor even does it seek particularly to offer programmes of social reform. The great aim of his teaching is to understand a process of historical transformation which proceeds before our eyes; scientific socialism is simply a conscious participation in this process. Agitation and revolutionary action can be effective only in so far as they comprehend and co-operate with the inevitable tendencies of social evolution. The change contemplated by socialism is an economic revolution brought about in accordance with the natural laws of historic evolution. We must also remember that Marx regards the economic factor as cardinal and decisive in history. Law and politics, religion and philosophy, are all moulded and controlled by the prevailing economic conditions. With this view of Marx is naturally associated his materialistic conception of history. 'According to Hegel, the thought-process, which he transforms into an independent subject under the name idea, is the creator of the real, which forms only its external manifestation. With me, on the contrary, the ideal is nothing else than the material transformed and translated in the human brain.' In short, the system of Marx is an evolutionary and revolutionary socialism, based on a materialistic conception of the world and of human history. He seeks to change the economic basis of society, and thereby to change the whole structure, but only by a conscious participation in, and willing co-operation with, historic tendencies, which in themselves are inevitable.

In his later and mature productions so far as published Marx has not given any definite forecast of the form likely to be assumed by the new society. As already indicated, his great aim is not to provide a recipe for social betterment but to elucidate an historical process which is inevitable, to make it clear to the consciousness of the class most profoundly interested—the proletariat—and as far as possible to shorten and alleviate the pangs of travail of the new era, which in any case will come to the birth when its time is fulfilled. Thus regarded, the life and work of Marx have a notable unity and reach and fixity of purpose. All that he did and wrote as scientific economist on the one hand and as agitator on the other, though at first sight inconsistent, is really formed and animated by the one idea.

Marx's leading works are mentioned above; a 3d edition of his *Kapital*, vol. i., appeared in 1883; vols. ii.-iii. were published under the editorship of Fr. Engels in 1885-95. Most economic works have something to say about Marx; see also studies by Gross (1885), Adler (1887), Spargo (1911), Beer (1921), an essay by Laski (1922), and Aveling's *Student's Marx* (1892), besides COMMUNISM, SOCIALISM, and works there named.

Marxstadt, formerly KATHERINENSTADT, a town of Russia, capital (1924) of the German Volga Republic. It was capital of the earlier German Volga Labour Commune (1918) from its institu-

tion till 1923, when it was superseded by Pokrovsk. Pop. 15,000.

Mary (Heb. *Miriam*, Gr. *Maria* or *Mariam*), 'the Mother of Jesus' (Matt. ii. 11; Acts, i. 14), called the Blessed Virgin, is held in high honour by Christians; and her intercession is invoked with a higher religious worship and a firmer confidence than that of all the other saints, not only in the Roman Church, but in all the Christian churches of the East. Of her personal history but few particulars are recorded in Scripture. Some details are filled up from the works of the early Fathers, especially their commentaries or deductions from the scriptural narrative, some from the apocryphal writings of the first centuries, and some from medieval or modern legends. The genealogy of our Lord in St Matthew is traced through Joseph (q.v.); and, as it is plainly assumed that Mary was of the same family with her husband Joseph, the evidence of the descent of the latter from David is equivalently an evidence of the origin of Mary from the same royal house. But the genealogy of Christ as traced in St Luke is commonly held to be the proper genealogy of his mother in the flesh, Mary. The incidents in her personal history recorded in Scripture are few in number, and almost entirely refer to her relations with our Lord. They will be found in Matt. i. ii., xii.; Luke i., ii.; John ii., xix.; and Acts, i., where the last notice of her is of her 'persevering in prayer' with the disciples and the holy women at Jerusalem after our Lord's ascension (Acts, i. 14). The apocryphal gospels entitled 'The Gospel of the Nativity of Mary,' and the 'Protevangelion of the Birth of Christ,' contain some additional, but, of course, unauthentic particulars as to the lineage, birth, and early years of Mary, among which is the miraculous story of her betrothal with Joseph, immortalised by the pencil of Raphael. As to her history after the ascension of her Son the traditions differ widely. A letter ascribed to the Council of Ephesus speaks of her as having lived with John at that city, where she died, and was buried. Another epistle, nearly contemporaneous, tells that she died and was buried at Jerusalem at the foot of the Mount of Olives. Connected with this tradition is the incident which has so often formed a subject of sacred art, of the apostles coming to her tomb on the third day after her interment, and finding the tomb empty, but exhaling an 'exceeding sweet fragrance.' On this tradition is founded the belief of her having been assumed into heaven, which is celebrated in the festival of the Assumption (q.v.). The date of her death is commonly fixed at the year of our Lord 63, or, according to another account, the year 48. Another tradition makes her survive the crucifixion only 11 years.

Of theological questions regarding the B.V.M. (*Beata Virgo Maria*), one is treated at IMMACULATE CONCEPTION. The perpetual virginity of Mary is not explicitly attested in Scripture, and there are even certain ambiguous phrases which at first sight seem to imply that children were born of her after the birth of Jesus, as that of his being called (Matt. i. 25; Luke, ii. 7) her 'first-born son,' and that of James and others being more than once called 'brothers of the Lord;' for which see JOSEPH. The perpetual virginity of Mary is held as a firm article of belief in the Roman and Eastern churches.

MARIOLATRY (Gr. *Maria*, and *latreia*, 'adoration') is the name given by polemical writers to the worship paid by Roman Catholics to the Virgin Mary. This name is intended to imply that the Catholic worship of the Virgin is the supreme worship of *latreia* or adoration, which Catholics earnestly disclaim, although, from her relation to our Lord, they hold her worship, which they style

hyperdulia, to be higher than that of all other saints. Many examples of prayers addressed to Mary (such as the 'Litany of the Sacred Heart of Mary'), of acts of worship done in her honour, and of expressions employed regarding her, are alleged by controversialists, for the purpose of showing that the worship of Mary in the Roman Church is in effect 'adoration.' To these and similar allegations Roman Catholics reply that many of the objected prayers and devotional practices are entirely unauthorised by the church, and that some of them are undoubtedly liable to misinterpretation; but they further insist that all such prayers, however worded, are to be understood, and are, in fact, understood by all Roman Catholics, even ordinarily acquainted with the principles of their faith, solely as petitions for the intercession of Mary, and as expressions of reliance, not on her own power, but on the efficacy of her prayers to her Son.

Although no trace is found in the New Testament of any actual worship of the Virgin Mary, yet Roman Catholic interpreters regard the language of the angel Gabriel, who saluted her as 'full of grace,' or 'highly favoured,' and as 'blessed among women,' and her own prediction in the canticle of the Magnificat, that 'all nations should call her blessed' (Luke, i. 48), as a foreshadowing of the practice of their church; and they rely equally on the language employed by the early Fathers, as, for instance, Irenæus, regarding the Virgin, although Protestants consider it as having reference to the Incarnation. But it seems quite certain that during the first ages the invocation of the Virgin and the other saints must have held a subordinate place in Christian worship; the reason for which, according to Roman Catholics, was probably the fear which was entertained of reintroducing among the recent converts from paganism the polytheistic notions of their former creed. But from the time of the triumph of Christianity in the 4th century, the traces of it become more apparent. St Gregory Nazianzen, in his panegyric of the virgin martyr Justina, tells that in her hour of peril she 'implored Mary the Virgin to come to the aid of a virgin in her danger.' But it was only after the heresy of Nestorius that the worship of Mary seems to have obtained its full development. His denial to her of the character of mother of God, and the solemn affirmation of that character by the ecumenical council of Ephesus (430 A.D.), had the effect at once of quickening the devotion of the people and of drawing forth a more marked manifestation on the part of the church of the belief which had been called into question. The 5th and 6th centuries, both in the East and in the West, exhibit clear evidence of the practice; and the writers of each succeeding age till the Reformation speak with gradually increasing enthusiasm of the privileges of the Virgin Mary, and of the efficacy of her functions as a mediator with her Son. St Bernard, and, still more, St Bonaventura, carried this devotional enthusiasm to its greatest height. The institution of the 'Rosary of the Virgin Mary,' the appointment of a special office in her honour, and, more than all, the fame of many of the sanctuaries which were held to be especially sacred to her worship gave a prominence to the devotion which Protestants find it difficult to reconcile with the honour which they hold due to God alone. The chief festivals of the Virgin, common to the Western and Eastern churches, are the Conception, the Nativity, the Purification, the Annunciation, the Visitation, and the Assumption. The Roman Church has several other special festivals, with appropriate offices—all, however, of minor solemnity. For accounts of representations of Mary in Art, see MADONNA, PIETÀ.

Mary I., queen of England, daughter of Henry VIII. by his first wife, Catharine of Aragon, was born at Greenwich on 18th February 1516. She was in her youth a great favourite with her father, and at the age of seven was betrothed to the Emperor Charles V. In her tenth year she was sent with certain commissioners and a species of viceregal court to the marches of Wales to carry out measures for the better government of that country. She was well educated, a good linguist, and fond of music. She was virtuous and pious, devoted to her mother, and devoted to her church. With the divorce of her mother her troubles began. Henry treated her with great harshness, and even forced her to sign a declaration that he was supreme head of the church, and that her mother's marriage had been 'by God's laws and man's law incestuous and unlawful.' During the reign of her half-brother Edward she lived in retirement, and no threats could induce her to conform to the new religion. On the death of Edward (6th July 1553), she became entitled to the crown by her father's testament and the parliamentary settlement. The Duke of Northumberland had, however, induced Edward and his council to set Henry's will aside in favour of Lady Jane Grey, to whom the duke had married his son Guildford Dudley. Lady Jane was proclaimed on 10th July, but the whole country suspected Northumberland and favoured Mary, who, supported by her friends, was able without bloodshed to enter London on 3d August in triumph. The queen now showed remarkable leniency towards her opponents. Northumberland and two others were executed as traitors, but Lady Jane and her husband were, for the present, spared. She had promised the mayor of London that she would not strain consciences, and she proceeded very gradually and cautiously to bring back the old religion. She reinstated the Catholic bishops and imprisoned some of the leading Reformers, but dared not restore the pope's supremacy, and she herself retained, under the advice of Gardiner, the title of supreme head of the church. Cardinal Pole was immediately on her accession designated papal legate, but prudence and the counsel of the emperor prevented his entering England. The question of the hour upon which all turned was the queen's marriage. Some thought of Courtenay, Earl of Devon; others of Cardinal Pole, then only in deacon's orders; but the queen, in the face of the fears and protests of the nation, obstinately and morbidly set her heart on Philip of Spain. The unpopularity of the proposal brought about the rebellion of Wyatt and an attack upon London. The rebellion was quelled mainly through the courage and coolness of the queen, but the consequences of her easy triumph were fatal to her. The hapless Lady Jane, who had seemingly been detained as a hostage for the good-behaviour of her friends, was with her husband and father brought to the block. The Princess Elizabeth was suspected, but without proof, of complicity in the treason, and was committed to the Tower. Injunctions were sent to the bishops to restore ecclesiastical laws to their state under Henry VIII. In July 1554, twelve months after Mary's accession, Philip landed and was married to her at Winchester. In the November following Pole entered England, and parliament, having made it sure that restitution would not be exacted from the owners of the confiscated church property, consented to petition for reconciliation to the holy see, and the realm was solemnly absolved from the papal censures. Soon after, the savage persecution which gave to the queen the name of 'Bloody Mary' began. In 1555 Ridley, Latimer, and other martyrs were brought to the stake. Cranmer was burned in March 1556, and Pole was consecrated Archbishop of Canterbury in his place. In August

1555 Philip had left England, to return only once more for a few weeks, and Gardiner died in November of the same year. Pole was now left supreme in the councils of the queen, and still the persecution raged; during the last three years of her reign some 300 victims perished in the flames. How far Mary herself was responsible for the cruelties practised is doubtful. During this period she was rendered almost helpless with ill-health. She was constantly deluded with the belief that she was about to become a mother. Broken down with sickness, with grief at her husband's heartlessness, and with disappointment at her childlessness, she became a prey to the deepest melancholy. Finally the evils which the nation predicted from the Spanish alliance came about. The queen was induced by Philip to enter upon war with France. The consequence was the loss of Calais to England. Mary died 17th November 1558.

See the histories of Lingard and Froude; P. F. Tytler, *England under the reigns of Edward VI. and Mary*; *Privy Purse Expenses of the Princess Mary*, with a memoir by Sir F. Madden; A. Strickland, *Lives of the Queens of England*; and other books cited at HENRY VIII., ELIZABETH, GREY (LADY JANE).

Mary II. (1662-94), wife of William III. (q.v.). **Mary, Queen of Scots**, was the daughter of James V. of Scotland by his second wife, Mary of Lorraine, daughter of Claude, Duke of Guise (q.v.), and widow of Louis of Orleans, Duke of Longueville. She was born at Linlithgow on the 7th or 8th of December 1542. Her misfortunes may be said to have begun with her birth. The tidings reached her father on his death-bed at Falkland, but brought him no consolation. 'The deil go with it!' he muttered, as his thoughts wandered back to the marriage with Bruce's daughter, which brought the crown of Scotland to the Stewarts—'it cam with ane lass, and it will pass with ane lass!' Mary became a queen before she was a week old. Within a year the Regent Arran had promised her in marriage to Prince Edward of England, and the Scottish parliament had declared the promise null. War with England followed, and at Pinkie Cleuch the Scots met a defeat only less disastrous than Flodden. But their aversion to an English match was unconquerable; they hastened to place the young queen beyond the reach of English arms, on the island of Inchmahome, in the Lake of Menteith, and to offer her in marriage to the eldest son of Henry II. of France and Catharine de' Medici. The offer was accepted; and in July 1548 a French fleet carried Mary from Dumbarton, on the Clyde, to Roscoff, in Brittany, whence she was at once conveyed to St Germain-en-Laye, and there affianced to the Dauphin.

Her next ten years were passed at the French court, where she was carefully educated along with the king's family, receiving instruction in the art of making verses from the famous Ronsard. On the 24th of April 1558 she was married to the Dauphin, who was six weeks younger than herself. It was agreed, on the part of Scotland, that her husband should have the title of King of Scots; but Mary was further betrayed into the signature of a secret deed, by which, if she died childless, both her Scottish realm and her right of succession to the English crown (she was the great-granddaughter of Henry VII.) were conveyed to France. On the 10th of July 1559 the death of the French king called her husband to the throne by the title of Francis II. The government passed into the hands of the queen's kinsfolks, the Duke of Guise and the Cardinal of Lorraine; but their rule was short-lived. The feeble and sickly king died on the 5th of December 1560, when the reins of power were grasped by the queen-mother, Catharine de' Medici, as regent for her next son,

Charles IX. Mary must have been prepared, under almost any circumstances, to quit a court which was now swayed by one whom, during her brief reign, she had taunted with being 'a merchant's daughter.' But there were other reasons for her departure from France. Her presence was urgently needed in Scotland, which the death of her mother, a few months before, had left without a government, at a moment when it was convulsed by the throes of the Reformation. Her kinsmen of Guise had ambitious projects for her marriage; great schemes were based on her nearness of succession to the English crown; and both these, it was thought, might be more successfully followed out when she was seated on her native throne.

She sailed from Calais on the 15th, and arrived at Leith on the 19th August 1561, having escaped the English ships of war which Elizabeth despatched to intercept her. Her government began auspiciously. The Reformation claimed to have received the sanction of the Scottish parliament, and if Mary did not formally acknowledge the claim, she was at least content to leave affairs as she found them, stipulating only for liberty to use her own religion—a liberty which Knox and a few of the more extreme Reformers denounced as a sin against the law of God. She is said to have rejected the violent counsels of the Roman Catholics; it is certain that she surrounded herself with Protestant advisers, her chief minister being her illegitimate brother, James Stuart, whom she soon afterwards created Earl of Moray. Under his guidance, in the autumn of 1562, she made a progress to the north, which, whatever was Moray's design, ended in the defeat and death of the Earl of Huntly, the powerful chief of the Roman Catholic party in Scotland. For the Chastelard episode, see CHASTELARD.

Meanwhile the courts of Europe were busy with schemes for Mary's marriage. The king of Sweden, the king of Denmark, the king of France, the Archduke Charles of Austria, Don Carlos of Spain, the Duke of Ferrara, the Duke of Nemours, the Duke of Anjou, the Scottish Earl of Arran, and the English Earl of Leicester were proposed as candidates for her hand. Her own preference was for Don Carlos, the heir of what was then the greatest monarchy in Christendom; and it was not until all hopes of obtaining him were quenched that she thought seriously of any other. Her choice fell, somewhat suddenly, on her cousin, Henry Stewart, Lord Darnley, son of the Earl of Lennox, by his marriage with a granddaughter of King Henry VII. of England. He was thus among the nearest heirs to the English crown, and his claims to the succession were believed to have the support of the great body of English Roman Catholics. But except this and his good looks he had no other recommendation. He was weak, needy, insolent, and vicious; his religion, such as it was, was Roman Catholic; his house had few friends and many enemies in Scotland; and he was three years younger than Mary. Her best friends, both Roman Catholic and Protestant, warned her against him, but in vain. The marriage was celebrated at Holyrood on the 29th July 1565. It was the signal for an insurrection by Moray and the Hamiltons, who hoped to be joined by the whole Protestant party. But their hope was disappointed; and the queen, taking the field in person, at once quelled the revolt, and chased the rebels beyond the Tweed.

Her triumph was scarcely over when misunderstandings began to arise between her and her husband. Darnley's worthlessness and folly became only too apparent; she was disgusted by his debauchery, and alarmed by his arrogance and

ambition. She had given him the title of king, but he now demanded that the crown should be secured to him for life, and that, if the queen died without issue, it should descend to his heirs. Mary hesitated to comply with a demand which would have set aside the settled order of succession; and what she refused to grant by favour the king prepared to extort by force.

Mary's chief minister prior to Moray's rebellion had been David Rizzio, a mean-looking Italian, of great astuteness and many accomplishments, but generally hated beyond the palace walls as a base-born foreigner, a court favourite, and a Roman Catholic. The king and Rizzio had been sworn friends, sharing the same table, and even sleeping in the same bed; but the king was now persuaded that it was Rizzio who was the real obstacle to his designs upon the crown. In this belief, he entered into a formal compact with Moray, Ruthven, Morton, and other chiefs of the Protestant party, undertaking, on his part, to prevent their attainer, or procure their pardon, and to support and advance the Protestant religion; while they, on the other part, bound themselves to procure the settlement of the crown upon him and his heirs, and to take and slay, if need were, even in the queen's palace and presence, every one who opposed it. The result of this conspiracy was the murder of Rizzio on the 9th of March 1566, the king leading the way into the queen's cabinet, and holding her in his grasp, while the murderers dragged the poor Italian into an ante-chamber, and, mangling his body with more than fifty wounds, completed what they deemed a justifiable act. When Mary learned what had been done she broke out in reproaches against the king as being the chief cause of the deed. 'I shall be your wife no longer,' she told him, 'and shall never like well till I cause you have as sorrowful a heart as I have at this present.' As had been agreed beforehand among the conspirators, Mary was kept prisoner in Holyrood; while the king, of his own authority, dismissed the parliament which was about to forfeit Moray and his associates in the late insurrection. The plot was thus far successful; but Mary no sooner perceived its objects than she set herself at work to defeat them. Dissembling her indignation at her husband's treachery and the savage outrage of which he had been the ringleader, she succeeded by her blandishments in detaching him from the conspirators, and in persuading him not only to escape with her from their power by a midnight flight to Dunbar, but to issue a proclamation in which he denied all complicity in their designs. The conspiracy was now at an end; Ruthven and Morton fled to England, while Moray was received by the queen; and the king, hated by both sides, because he had betrayed both sides, became an object of mingled abhorrence and contempt.

It was an aggravation of the murder of Rizzio that it was committed, if not in the queen's presence, at least within a few yards of her person, only three months before she gave birth (on the 19th June 1566) to the prince who became James VI. As that event drew near, the queen's affection for her husband seemed to revive; but the change was only momentary; and before the boy's baptism, in December, her estrangement from the king was greater than ever. Divorce was openly discussed in her presence, and darker designs were not obscurely hinted at among her friends. The king, on his part, spoke of leaving the country; but before his preparations were completed he fell ill of the smallpox at Glasgow. This was about the 9th of January 1567. On the 25th Mary went to see him, and, travelling by easy stages, brought him to Edinburgh on the 31st. He was lodged in a small mansion beside the Kirk of the Field, nearly

on the spot where the south-east corner of the Old College now stands. There Mary visited him daily, and slept for two nights in a room below his bedchamber. She passed the evening of Sunday the 9th of February by his bedside, talking cheerfully and affectionately with him, although she is said to have dropped one remark which gave him uneasy forebodings—that it was much about that time twelvemonth that Rizzio was murdered. She left him between ten and eleven o'clock to take part in a masque at Holyrood, at the marriage of a favourite valet. About two hours after midnight the house in which the king slept was blown up by gunpowder, and his lifeless body was found in the neighbouring garden.

The chief actor in this tragedy was undoubtedly James Hepburn, Earl of Bothwell (q.v.). What part Mary herself had in the crime continues matter of historical controversy, centring mainly in the question of the authenticity of the Casket Letters. These so-called letters were declared by the Earl of Morton (q.v.) to have been found by him (20th June 1567) in a silver casket taken from a servant of Bothwell. They consist of eight letters and some verses, all said to have been written by Mary to Bothwell between January and April 1567. None of the originals are known to exist. The letters, if genuine, undoubtedly establish Mary's complicity. That they are genuine is now most generally admitted, for while their authenticity still lacks final proof, any argument so far adduced for their invalidation has failed to satisfy the canons of historical criticism. In any case, it is certain that the course of subsequent events is far from being consistent with Mary's ignorance of the plot for the removal of Darnley. On the 12th of April Bothwell was brought to a mock-trial, and acquitted; on the 24th he intercepted the queen on her way from Linlithgow to Edinburgh, and carried her, with scarcely a show of resistance, to Dunbar; on the 7th of May he was divorced from his comely and new-wedded wife; on the 12th Mary publicly pardoned his seizure of her person, and created him Duke of Orkney; and on the 15th—only three months after her husband's murder—she married the man whom every one regarded as his murderer.

This fatal step at once arrayed her nobles in arms against her. She was able to lead an army against them, but it melted away without striking a blow on the field of Carberry (15th June), when nothing was left to her but to abandon Bothwell and surrender herself to the confederate lords. They led her to Edinburgh, where she knew fits of frenzied despair.

From Edinburgh she was hurried to Lochleven, where, on the 24th of July, she was prevailed upon to sign an act of abdication in favour of her son, who, five days afterwards, was crowned at Stirling. Escaping from her island-prison (where she was confined of still-born twins) on the 2d of May 1568, she found herself in a few days at the head of an army of 6000 men. On the 12th it was met and defeated by the Regent Moray at Langside, near Glasgow. Four days afterwards, in spite of the entreaties of her best friends, Mary crossed the Solway, and threw herself on the protection of Queen Elizabeth, only to find herself a prisoner for life. From Carlisle, her first place of captivity, she was taken, in July, to Bolton; from Bolton she was carried, in February 1569, to Tutbury; from Tutbury she passed in succession to Wingfield, Coventry, Chatsworth, Sheffield, Buxton, Chartley, and last of all to Fotheringhay. The presence of Mary in England was a constant source of uneasiness to Elizabeth and her advisers. A large minority in the country were still Catholic, and naturally looked to Mary as the likely restorer

of the old faith. Plot followed plot, therefore, to effect her deliverance, and to place her on the throne of Elizabeth. Of these plots the most famous is that of Antony Babington, which had for its object the assassination of Elizabeth and the deliverance of Mary. The conspiracy was discovered; certain letters of Mary approving the death of Elizabeth fell into the hands of Walsingham; and, mainly on the evidence of copies of these letters, Mary was brought to trial in September 1586. Sentence of death was pronounced against her on the 25th of October; but it was not until the 1st of February 1587 that Elizabeth took courage to sign the warrant of execution. It was carried into effect on the 8th, when Mary laid her head upon the block with the dignity of a queen and the constancy and resignation of a martyr, evincing to the last her devotion to the church of her fathers. Five months afterwards her body was buried with great pomp at Peterborough, whence, in 1612, it was removed to King Henry VII.'s Chapel at Westminster, where it still lies in a sumptuous tomb erected by James VI.

Mary's character, according as views differ of her complicity in the death of Darnley, continues matter of debate. Her beauty and accomplishments have never been disputed. She was confessed by every one to be the most charming princess of her time. Her large sharp features might perhaps have been thought handsome rather than beautiful, but for the winning vivacity and high joyous spirit which animated them. It has been questioned whether her eyes were hazel or dark gray, but there is no question as to their star-like brightness. Her complexion, although fresh and clear, would seem to have been without the brilliance so common among our island beauties. Her hair appears to have changed with her years from a ruddy yellow to auburn, and from auburn to dark brown or black, turning gray long before its time. Her bust was full and finely shaped, and she carried her large stately figure with majesty and grace. She showed to advantage on horseback, and still more in the dance. The charm of her soft, sweet voice is described as irresistible; and she sang well, accompanying herself on the harp, the virginal, and still oftener on the lute, which set off the beauty of her long, delicate, white hand. The consciousness how that hand was admired may have made it more diligent in knitting and in embroidery, in both of which she excelled. Her manner was sprightly, affable, kindly, frank perhaps to excess, if judged by the somewhat austere rule already beginning to prevail among her Scottish subjects. She spoke three or four languages, was well and variously informed, talked admirably, and wrote both in prose and in verse, always with ease, and sometimes with grace or vigour. In the ring of which she was the centre were statesmen like Moray and Lethington, soldiers like Kirkcaldy of Grange, men of letters like Buchanan, Leslie, Sir Richard Maitland, and Sir James Melville. The first poet of France published verses deploring his absence from her brilliant court; Damville, the flower of French chivalry, repined at the fate which called him away from it so soon; Brantôme and the younger Scaliger delighted to speak, in old age, of the days which they passed beneath its roof.

Mary's prose-writings have been collected by the enthusiastic devotion of Prince Alexander Labanoff, in his *Recueil des Lettres de Marie Stuart* (7 vols. 1844). Setting aside the twelve so-called 'sonnets' which she is said to have written to Bothwell, and which survive only in a French version of an English translation, no more than six pieces of her poetry, containing in all less than 300 lines, are now known. They have no remarkable merit. The best is the

poem of eleven stanzas on the death of her first husband Francis II., printed by Brantôme. The longest is a *Meditation* of a hundred lines, written in 1572, and published two years afterwards by her ever faithful follower, Bishop Leslie of Ross. All are in French, except one sonnet, which is in Italian. The lines beginning 'Adieu, plaisant pays de France,' ascribed to her, are, according to Barbé (*In Byways of Scottish History*, 1912), by Brantôme; or, as some think, by a journalist, Meusnier de Querlon (died 1780). A volume of French verse on the *Institution of a Prince*, which she wrote for the use of her son, has been lost since 1627, along with a Latin speech in vindication of learned women, which, when no more than thirteen, she delivered in the Louvre to the French court.

The literature is extensive. Among the chief works, apart from the *Histories of Scotland* by Keith, W. Robertson, Laing, P. F. Tytler, Burton, Hume Brown, &c., and of England by Hume, Froude, &c., are Jebb's *De Vita et Rebus Gestis Mariæ Scotorum Reginæ* (1725); J. Anderson's *Collections Relating to the History of Mary, Queen of Scotland* (1727-28); Goodall's *Examination of the Letters said to be written by Mary, Queen of Scots, to James, Earl of Bothwell* (treats the letters as forgeries; 1754); W. Tytler's *Inquiry into the Evidence against Mary, Queen of Scots* (vindictory; 1759, 1790); G. Chalmers's *Life of Mary, Queen of Scots* (vindictory; 1818, 1822); David Laing's edition of *John Knox's History of the Reformation* (1846-64); the *Life* by Agnes Strickland in her *Lives of the Queens of Scotland* (1850-59; new ed. 1873); A. de Montaignon's *Latin Themes of Mary Stuart* (1855); Prince Labanoff's *Notice sur la Collection des Portraits de Marie Stuart* (1856); Mignet's still valuable *Histoire de Marie Stuart* (condemnatory; 1852); Teulet's *Lettres de Marie Stuart* (1859); Chéruef's *Marie Stuart et Catherine de Médicis* (1858); Joseph Robertson's *Catalogues of the Jewels, Dresses, Furniture, Books, and Paintings of Mary, Queen of Scots* (1863); Hosack's *Mary, Queen of Scots, and her Accusers* (a defence; 1870-74; a popular ed. 1888); books by Petit and De Flandre (1874), Chantelauze (1876), and the interesting document by Claude Nau, Mary's secretary (ed. by Father Stevenson, 1883); Leader's *Mary Stuart in Captivity* (1881); Baron Alphonse de Ruble's *La Première Jeunesse de Marie Stuart* (1891); Jane T. Stoddard's *The Girlhood of Mary, Queen of Scots* (1908); Baron Kervyn de Lettenhove's *Marie Stuart* (2 vols. 1889), dealing with only the two last years of her life; T. F. Henderson's *Casket Letters* (1890), supporting the authenticity of the letters, and giving for the first time Morton's declaration regarding the manner in which the casket is said to have fallen into his hands; Philippon's *Histoire du Règne de Marie Stuart* (3 vols. 1891-92); Skelton's *Impeachment of Mary Stuart* (a defence; 1876) and his sumptuous *Mary Stuart* (1893); Dr Hay Fleming's *Mary Queen of Scots* (1897); S. Cowan's exculpatory monograph (1901); Andrew Lang's *Mystery of Mary Stuart* (sums up against the queen on the main charge; 1901); the *Papal Negotiations and Letter to Guise*, edited by Father Pollen, S.J. (1901-4); Mumby's *Elizabeth and Mary Stuart* (1914), and *The Fall of Mary Stuart* (1921); Steuart (ed.), *Trial of Mary Queen of Scots* (1923); Mahon's *The Indictment of Mary Queen of Scots* (1923), and *Mary Queen of Scots* (1924); Lives by Florence A. MacCunn (1905) and T. F. Henderson (1905); and for portraits, Cust's *Authentic Portraits of Mary Queen of Scots* (1903).

Maryborough, a port of Queensland, on the Mary River (here spanned by a wooden bridge), 25 miles from its mouth and 180 N. of Brisbane, with which there is communication by steamer and rail. Gold from Gympie and copper from Mount Parry and other mines, with sugar and timber, are shipped to Brisbane for export. There are great engineering works and timber mills. Pop. 11,000.

Maryland, one of the original states of the American Union, lies between the parallels of 37° 53' and 39° 44' N. lat., and the meridians of 75° 4' and 79° 33' W. long. It contains 12,320 sq. m.—very nearly the size of Holland—of which

about one-fifth is water. The length from east to west is 196 miles, and the breadth varies from 128 to 3 or 4 miles. It is separated from Pennsylvania and Delaware by 'Mason and Dixon's Line' (q.v.); the south-western border follows the course of the Potomac River, the whole of which, with the exception of about 12 miles in the District of Columbia (q.v.), is under the jurisdiction of Maryland, down to the low-water mark on the Virginia side.

The elevation varies greatly, from sea-level to 3500 feet. In the west it is mountainous, being crossed by the Alleghanies; in the middle, hilly and rolling; in the east and south-east, low and undulating. A line drawn from the mouth of the Susquehanna to the city of Washington will cut the state into two nearly equal parts, and divide the mountain and hill country from the low lands on both sides of the Chesapeake Bay. The productions and occupations are largely determined by the physical features—in the west coal and lumber; in the middle corn and wheat; in the east fish, fruit, and vegetables. The climate is generally regarded as unusually healthful. The mean summer temperature is 75° F., the mean winter temperature 34° F. The annual rainfall varies from 38 inches in the mountains to 46 inches near the Atlantic coast. The mountain air is regarded as a specific for hay-fever.

The geological formations vary with the surface elevations. The southern section of both the shores of the Chesapeake Bay is alluvial; north of the alluvial deposit is a Tertiary formation; north-west of this come metamorphic rocks; west of them a wide belt of Silurian and Devonian formation; and still farther west Carboniferous strata beginning at Cumberland. In the Tertiary we find marl in abundance. In the metamorphic rocks gneiss, granite, limestone, and iron. In the Carboniferous extensive veins of bituminous coal of the best quality; one remarkable vein in the George's Creek district is 14 feet thick. Over 200 kinds of marble have been found in the state, some of them equal to the Italian marbles. Near Baltimore are large beds of clay, from which bricks of peculiar excellence and beauty are manufactured. Gold, silver, and copper are produced in small quantities. Kaolin and magnesite are found, and among numerous other minerals, some present in large quantities, are soapstone, glass sand, chrome, cements. Coal is far the most important mineral product, and in value is followed by building stones.

The soil is well adapted to cultivation, with the exception of the mountain tops in the west, and a small proportion of marsh land in the east. The forest-trees are principally pine, chestnut, and oak; hickory and walnut are becoming scarce. The staple fruit-trees are the apple, the peach, and the pear. Tobacco is the principal crop in the peninsula between the Chesapeake and the Potomac, as it was the main reliance of the early settlers, constituting even their ordinary medium of exchange. Tomatoes in large quantities for canning, small fruits (especially strawberries), and all kinds of vegetables are cultivated on the eastern shore and sent to the markets of Baltimore, Philadelphia, and elsewhere. The mountains still contain some deer; and wild geese, swans, and turkeys are found in considerable numbers at the proper season, as well as woodcock, grouse, and quail (locally called partridge). Immense flocks of wild ducks of various species throng the estuaries of the Chesapeake on the approach of cold weather: the 'canvas-back' is found nowhere else in perfection.

The Chesapeake Bay (q.v.) divides Maryland into two unequal portions, the Eastern and the Western Shore. With its estuaries it gives the state a coastline of more than 500 miles, and an abundance of

steamboat landings: on the Eastern Shore there is scarcely a farm more than 5 miles distant from a river accessible to steamboats of light draught. Shad and herring are caught in large numbers, and the oyster fisheries are second in importance only to those of Virginia. For the leading manufactures see BALTIMORE, where most are located. Baltimore is also the principal port and great commercial centre of the state. Maryland has over 2000 miles of railway (steam and electric), and two canals (from Cumberland, in the west, to Washington, 184½ miles, and between the Chesapeake and Delaware Bays, 12½ miles).

In Maryland education is compulsory for children in a system of free public schools. Coloured children are educated in separate schools, but under the same management. The percentage of illiteracy is low. There is in every county a high school or academy which gives secondary instruction and fits pupils for college. The colleges supported in whole or in part by the state are St John's College, Annapolis (originally King William's School); Washington College, Chestertown, Kent county, to the foundation of which George Washington contributed £100 sterling; the Agricultural College, near Bladensburg; and the Western Maryland College, Westminster. There are also several denominational colleges. The foremost of the educational institutions of Maryland is the Johns Hopkins University, in Baltimore, where also are Maryland University, Goucher College (for women), and the Peabody Institute (for education in music). There is a school for the feeble-minded at Pikesville; a school for the deaf and dumb at Frederick; and in Baltimore a school for the blind, and a school for coloured blind children and deaf-mutes, all supported by the state. At Catonsville there is an asylum for the insane. The United States Naval Academy is at Annapolis.

Maryland returns two senators and six representatives to congress. The legislature is styled the General Assembly, and consists of two houses—the Senate and the House of Delegates. The Senate, elected by the people, is composed of one member from each of the twenty-three counties and four from the city of Baltimore. The House of Delegates has one hundred and two members, from Baltimore city and the several counties in proportion to their respective populations. The seat of government is at Annapolis. Baltimore had in 1920 a pop. of 733,826. Other principal towns are Cumberland, Hagerstown, Frederick, Frostburg, Catonsville, on the Western Shore; Salisbury, Cambridge, Crisfield, on the Eastern. Pop. of state (1830) 447,030; (1860) 687,049; (1880) 934,943; (1900) 1,188,044; (1920) 1,449,661.

History.—In 1632 Charles I. of England issued a patent to Cecil Calvert, Lord Baltimore, granting him all the land 'from Watkins Point on the Bay, northward to the 40th degree of latitude, and from the Atlantic Ocean and Delaware Bay on the east to the Potomac River on the west.' This grant included not only the present Maryland, but also parts of Pennsylvania and Delaware, and many vexatious disputes resulted, some of which were settled only in 1890. The district was named in honour of Henrietta Maria, Charles's queen. In March 1634 a party of English gentlemen and their servants and retainers, under the command of Leonard Calvert, a brother of Lord Baltimore, landed on the shore of a river now called St Mary's, a branch of the Potomac, and bought from the Indians a tract of land. The friendly relations thus commenced with the Indians and but rarely interrupted, together with the announcement of toleration and protection to all Christians of whatever shade of religious belief, led to the rapid and

peaceful growth of the new colony. Maryland was among the first of the colonies to take an active part in the War of Independence. In the Civil War (1861-65) the people of Maryland were divided in sentiment, but the state remained within the Union. See *Histories* by Scharf (1879) and McSherry (1855; revised by B. B. James, 1905).

Maryland. See LIBERIA.

Marylebone, or ST MARYLEBONE, a metropolitan and parliamentary borough (returning, since 1918, one member, till then two) in the north-west of London, contains Regent's Park with the Zoological Gardens, Lord's cricket ground, the Queen's Hall, Hertford House (Wallace Collection), Harley Street, and Marylebone railway station (London and North Eastern Railway); pop. 104,000. See LONDON.

Maryport, a seaport of Cumberland, at the mouth of the Ellen, 28 miles SW. of Carlisle, gets its name from the fact that Mary, Queen of Scots, landed here in her flight from Scotland (1568), though it was called Ellenfoot down to 1750, when its harbour was constructed. A new dock was opened in 1884. Shipbuilding and its kindred employments are carried on, and there are iron-foundries and iron-furnaces, sawmills, flour-mills, tanneries, breweries, &c. The exports are chiefly coal and iron. Near by is a Roman fort where many antiquities have been found; pop. 11,000.

Marysville, capital of Yuba county, California, at the junction of the Yuba and the Feather rivers, at the head of navigation, 52 miles by rail N. of Sacramento. It has an extensive trade, and flour, iron-founding, woollen, and other industries. Dredge gold-mining is carried on. Pop. 5000.

Masaccio ('Slovenly Tommy'), the nickname of TOMMASO GUIDI, a Florentine painter, born in 1401 or 1402 in the Arno valley, probably at Castel San Giovanni. A reputed pupil of Masolino, he was enrolled in the Florentine guild of painters in 1424. Whilst still a young man he may have executed in the church of St Clement, Rome, a fresco of the Crucifixion and scenes illustrating the lives of some of the later saints; modern criticism, however, tends generally to disallow the claim. His greatest achievements, in any case, were wrought on the walls of the Carmine church, Florence, especially in the Brancacci chapel. It has been matter of controversy which pictures precisely were from the brush of Masaccio; Masolino worked at the same walls before him and Filippino Lippi after him. Those which are assigned to him beyond doubt or question are 'Expulsion from Paradise' (greatly admired by Raphael, who repeated the design in the loggia of the Vatican), 'Peter and the Tribute-money,' 'Temptation of Adam and Eve,' 'Peter Preaching,' and the same saint 'Baptising,' 'Healing the Sick,' 'Giving Alms,' and (in part) 'Restoring the Young Man to Life.' Apart from his frescoes Masaccio's major effort was his Pisan altarpiece, the various scattered and unidentified portions of which have only been rediscovered as a result of modern research, and are now to be found in five distinct collections. Masaccio's work marks an advance in Italian painting, in that it exhibits a more vigorous and correct representation of nature, with improved perspective and harmony of arrangement between figures and background. His influence on the Italian Renaissance was far-reaching, and he acted as a constant stimulus to the greatest masters of the 15th century. Towards the end of 1428 Masaccio suddenly left Florence, and is reported to have gone to Rome and to have died there before the year 1429 ran out. See a work by Enrico Somaré (Milan, 1924).

Masai, a people of East Equatorial Africa, dwelling in a district that stretches from 1° N. to 5° S. lat., and from 34° to 38° E. long., and includes Kilima-Njaro, Kenya, and Lake Baringo. The southern half of the district is low and barren, with no rivers and little rain, whilst in the north it rises into a plateau-region (5000 to 9000 feet), rich in running streams, forests, and grass-land. The Masai are not a Negro or Bantu race; they resemble the Gallas, being men of magnificent stature and Apollo-like forms, though their faces are ugly and ferocious in expression. This is due to the warlike habits of their youth, when, for nearly a score of years, they live in military kraals, spending their time alternately in idleness and on the war-path, eating nothing but beef, drinking nothing but milk, and having indiscriminate intercourse with the unmarried girls of the tribe. After marriage, which takes place when they lay aside the habits of the warrior, they settle down as cattle-breeders. The arms of the warriors consist of an ox-hide shield, a spear with a blade 2 to 2½ feet long and 3 inches broad affixed to a shaft of 15 inches, a sword, and a knobkerry. They are an aristocratic race, and clever public speakers; menial work is done by the women and boys. They speak a Hamitic language. See Hollis, *The Masai* (1905), and Merker, *Die Masai* (1910 ed.).

Masaniello (properly TOMMASO ANIELLO), a fisherman of Amalfi, born in 1623, was the leader of the revolt which took place in Naples in July 1647 against the Spanish viceroy, the Duke of Arcos. The people had been exasperated by oppression, and great excitement had been produced by a new tax upon fruit. Masaniello himself was aggrieved by the harsh treatment which his wife had received after being detected in an attempt to smuggle a little flour. Taking advantage of a quarrel between the fruit-sellers and the tax-collectors on 7th July 1647, Masaniello stirred up the multitude to a revolt. Their triumph was complete; palaces and public buildings were plundered, mostly for arms, a bloody popular justice was executed, and the viceroy was forced into a regular treaty with Masaniello in the church of the Carmelites on 13th July. But success and weight of responsibilities—some say poison—turned his head; he gave himself up to excess and capricious despotism, and, temporarily deserted by his friends, was assassinated by agents of the viceroy, or perhaps executed, on 16th July. Masaniello is the subject of an opera by Auber (q.v.).

Masaryk, THOMAS GARRIGUE, Czech writer and politician, was born at Göding, in Moravia, 7th March 1850. After working as a blacksmith, he studied at Vienna and Leipzig, became a dozent in philosophy at Vienna, and professor (1882) in the Czech university of Prague. In 1891-93 he sat in the Austrian Reichsrat as leader of the Young Czech 'realist' movement. Thereafter he wrought to set nationalism on a new footing, giving it a broader outlook. Again elected to the Reichsrat in 1907, he was a champion of general self-determination, an exposé of political fictions, and had a share in forwarding South Slav unity. On the outbreak of the Great War he escaped to Italy, became a lecturer in King's College, London, and organised the movement for Czechoslovak independence. He was first president of the new republic (1918), and was re-elected in 1920. Among many books on philosophical and political subjects he wrote *Grundlagen des Marxismus* (1898), and *The Spirit of Russia* (i. and ii. 1916). Hermann Bahr described him as a mixture of Tolstoi and Walt Whitman.

Mascagni, PIETRO, composer, born 7th December 1863 at Leghorn, produced in 1890, after a some-

what irregular musical education, and in competition for a prize, the brilliantly successful one-act opera *Cavalleria Rusticana*, the plot being taken from a story by Verga (q.v.). Later works were *L'Amico Fritz* (1891, based on Erckmann-Chatrian), *I Rantzau* (1892), *Verone*, *Ratcliffe*, *Iris*, *Parisina*, *Lodoletta*, *Il piccolo Marat*, besides songs and ballads.

Mascara, a fortified town of Algeria, 50 miles S.E. of Oran, on a slope of Atlas. It is an important trading-centre. Abd-el-Kader was born in the neighbourhood, and the place was the seat of his power. Pop. 29,000.

Mascarenes. See MAURITIUS.

Masefield, JOHN, poet, dramatist, and novelist, was born in Shropshire in 1875. Running away from school he lived a vagabond life on sea and land, but returned in the end to England, where a brother of the poet Yeats procured him a start in literature. For a time he was on the staff of the *Manchester Guardian*. His first poems, *Saltwater Ballads* (1902) and *Ballads* (1903) were of the sea, as were also his first prose works—two collections of short stories, *A Mainsail Haul* (1905) and *A Tarpsailin Muster* (1907), and a novel, *Captain Margaret* (1908). These earliest works caused no stir, but a measure of recognition came with *The Tragedy of Nan* (1909), a play, and fame with *The Everlasting Mercy* (1911), a narrative poem much criticised for its ruthless realism. Among later works were the narrative poems, *The Widow in the Bye Street* (1912), *Dauber* (1913), *The Daffodil Fields* (1913), *Reynard the Fox* (1920), *Right Royal* (1920), *King Cole* (1923); collections of shorter poems in *Philip the King* (1914), *Lollington Downs* (1917), *Enslaved* (1920); the plays, *The Tragedy of Pompey the Great* (1910), *The Faithful* (1915), *Good Friday* (1916), *Melloney Holtspur* (1922); the novels, *Multitude and Solitude* (1909), *The Street of To-day* (1911), *Sard Harker* (1924). Masefield has also produced works in literary criticism, as *Shakespeare* (1911), and in history, as *Sea-Life in Nelson's Time* (1905), *On the Spanish Main* (sketches of buccaneers, 1906), and an edition (1907) of Dampier's *Voyages*. *Gallipoli* (1916) and *The Old Front Line* (1918) were prose sketches of the Great War. Masefield is to be ranked among the foremost English writers of his time. He reveals the influence of Chaucer, Whitman, Kipling, Conrad, Hardy, and Yeats, and the spirit of the country and of the sea is in his work, as well as a realism sombre at times. He finds in the poor and the hard-pressed a subject, and speaks pity and justice for all broken things. If the narrative poem is his characteristic and probably most significant form, he is distinguished no less by the charm of his lyrics. With a tendency to over-production, there is mixed with the best of his work much that is careless and inferior. See *Studies* by W. H. Hamilton (1922) and C. Biggame (1924).

Masham, MRS. See MARLBOROUGH.

Mashonaland, or MASHUNALAND, a region of Rhodesia (q.v.) north-east of Matabeleland, embraces the plateau (4000-4600 feet) whose backbone is formed by the Umvukwe Mountains, and in which some of the chief feeders of the Zambezi, Limpopo, Sabi, and Mazoe have their origins. It is healthy, with rich soil, grass all the year round, and an abundance of running streams. On the Matabele invasion, those Mashona who escaped massacre took refuge in the mountainous districts, building their villages on almost inaccessible crags. They are the best husbandmen in South Africa, and grow rice, Kaffir corn, maize, ground-nuts, sweet potatoes, tobacco, and cotton; this last they weave into blankets. They are also good iron-workers. Iron, copper, and gold exist in immense quantities.

Mauch in 1871 discovered many old mines that had been worked with some scientific skill, especially at Zimbabwe (q.v.). Mashonaland was put under British protection in 1888.

Masinissa, king of the Massylii or Eastern Numidians, was born about 238 B.C., and brought up at Carthage. Having helped the Carthaginians to subdue Syphax, king of the Massaesylii or Western Numidians, he accompanied his allies to Spain and fought valiantly and successfully against the Romans. But about 210 the Carthaginians gave his promised bride to Syphax; and for this and other reasons he became henceforward an ally of Rome. He received as his reward the kingdom of Syphax, together with large portions of the territory of Carthage. But before he died, in 149 B.C., he slackened his zeal for Rome.

Mask (through the medium of Fr. and Span. from the Arabic *maskharat*, 'a jester') is an artificial covering for the face, worn by many different peoples for different purposes. Masks are common amongst the inhabitants of New Britain, New Ireland, New Guinea, and the adjoining islands, amongst the North American Indians and the Eskimo, the Chinese, the aborigines of Australia, and some Negro tribes. The masks these peoples use are generally very hideous and repellent in aspect, being designed expressly to inspire terror in the mind of the beholder. The primary object is to scare away the demons and spirits who bring misfortunes, diseases, national calamities, or other evils upon the tribe; the exorcism is usually practised by processions of masked men, who dance and utter loud cries calculated to frighten the enemy away. Where totemistic beliefs prevail, it is customary for the people to celebrate dances clad in the skins of wild animals, and on such occasions masks are worn shaped to resemble the animals represented in the dance. It is highly probable that practices of a similar nature were current amongst the primitive Greeks, Egyptians, and other peoples. The myth of the snake-haired Gorgon is traced back to this origin; so too is the practice of covering the faces of the dead with a mask, intended to keep the demons away from them whilst they were on their journey to the abode of shades, a practice common to the ancient Greeks and Egyptians, and the ancient Peruvians and Mexicans. Death-masks of gold have been found in tombs of Mycenæ and Kertch; those of the Peruvians were made of silver and wood; some found at Carthage were of clay, painted in divers colours; and copper and wood were used in Mexico. Masks, besides being worn by living men, were sometimes attributed to their gods, as in ancient Egypt and Greece, and in India, or were put on over the faces of the gods' images, as in ancient Mexico. The Greeks, moreover, in their theatrical performances, employed masks shaped to represent the expression of a particular emotion or passion, as rage, grief, sly cunning, &c. These, made of linen, tree-bark, leather, or even wood, had large funnel-shaped mouth-openings, for the purpose of giving the voice of the actor a penetrating sound (whence Lat. *per-sona* = 'a mask'), so that it might be heard all over the vast theatres in which he had to act. Passing on to the Romans, the custom of putting masked actors on the stage was transmitted by them to the Italian theatres of the middle ages; nearly all the actors in the *Commedia dell'Arte* wore masks. The custom was also practised in the English Masque (q.v.) of Elizabethan and subsequent times. The Masquerade (q.v.) or masked ball is a survival of the same observance; but in it the purpose is disguise of identity, as in the case of the Man with the Iron Mask (see IRON MASK).

Maskat. See MUSCAT, OMAN.

Maskelyne, NEVIL, D.D., astronomer and physicist, was born in London, 6th October 1732, and educated at Westminster School and at Cambridge. In 1758 he was admitted to the Royal Society, and having devoted himself to astronomy, was appointed astronomer-royal in 1765. During his forty-six years' tenure of that office he improved methods and instruments of observation, invented, though in part anticipated by the Abbé Rochon, the prismatic micrometer, and made many important and accurate observations. In 1774 he measured the earth's density from the deflection of the plumb-line at Schiehallion, Perthshire (see EARTH). The first of his very numerous publications was the *British Mariner's Guide* (1763). With the issue for 1767 he founded the *Nautical Almanac*. His *Tables for Computing the Places of the Fixed Stars, &c.*, were published by the Royal Society in 1774. In 1776 he produced the first volume of the *Astronomical Observations made at the Royal Observatory, Greenwich, from 1665*—an invaluable work still continued. He was rector from 1775 of Shrewsbury, Salop, and from 1782 of North Runcton, Norfolk, and died 9th February 1811.

Mason, ALFRED EDWARD WOODLEY, novelist and dramatist, was born in London, 7th May 1865, and educated at Dulwich College and at Trinity College, Oxford. For a time he toured with a theatrical company, but later abandoned the stage for literature, and in 1895 produced his first novel, *A Romance of Wastdale*. Of numerous later novels, *The Courtship of Morrice Buckler* (1896; dramatised 1897), *The Four Feathers* (1902), *The Broken Road* (1907), *Running Water* (1907; dramatised 1922), the detective story *At the Villa Rose* (1910; dramatised 1920), *The Turnstile* (1912), *The Summons* (1920, embodying experiences during the Great War), and *The House of the Arrow* (1924) may be mentioned. Apart from the dramatisation, where that has been done, of his novels, he wrote also the plays, *Colonel Smith* (1909), *The Witness for the Defence* (1911), and *Open Windows* (1913). In 1906–10 he was a Liberal member of parliament.

Mason, GEORGE HEMMING, A.R.A. (1818–72), was born in Staffordshire. He first studied medicine, but in 1845 established a studio at Rome, and did not return to England till 1858. His best works were 'The Evening Hymn' (1868), 'Girls Dancing by the Sea' (1869), and 'The Harvest Moon' (1872). His pictures show great pathos and rich effects of colour.

Mason, SIR JOSIAH, manufacturer and philanthropist, was born at Kidderminster, 23d February 1795. From street-hawker he became the largest pen-maker in the world; for long he was maker to Perry. As a partner he later financed the Elkingtons in their introduction of electro-plating. The great fortune acquired in these ways he distributed largely in public charity. Thus he erected and endowed almshouses, and an orphanage at Erdington, and was the founder of the Josiah Mason College, expanded in 1900 into the university of Birmingham. He died at Erdington, 16th June 1881. See the *Memoir* by Bunce (1890).

Mason, WILLIAM (1724–97), minor poet, more famous as the friend of Gray, was born probably at Kingston-upon-Hull, and educated at Cambridge. By his *Musæus* (1747), a poetic lament for the death (1744) of Pope written in imitation of *Lycidas*, he attracted Gray. Later he published two absurd but ambitious tragedies, *Elfrida* and *Caractacus*; the *English Garden* (1772–82), a long and tedious poem in blank verse; and the *Memoirs of Gray* in 1775, a work with serious defects. Mason became in 1754 vicar of Aston, in Yorkshire, and

later also precentor and canon of York. See a book by J. W. Draper (1925).

Mason and Dixon's Line, the boundary line between Maryland and Pennsylvania. The line runs due east and west, and takes its name from two English engineers, Charles Mason and Jeremiah Dixon, who, between 1763 and 1767, surveyed it to a point some 244 miles west of the Delaware River; further advance was then checked by Indians, but the boundary was later completed by others. The running of the line marked the close of an eighty years' boundary dispute between the Baltimores and the Penns, proprietors respectively of Maryland and of Pennsylvania. The eastern part of the line was originally marked with milestones brought from England, every fifth of which bore on one side the arms of Baltimore, and on the other those of Penn. Owing to the removal of the stone marking the north-east corner of Maryland this point was again determined by survey in 1849-50; while, local disputes arising owing to the absence of stones on the western section of the boundary, a re-survey was undertaken in 1901-3. Previous to the Civil War the line was popularly accepted as marking the boundary dividing the free from the slave states. At the same time as they ran the boundary between Maryland and Pennsylvania, Mason and Dixon also surveyed and marked the boundary between Maryland and Delaware.

Mason and Slidell. See TRENT AFFAIR.

Masonry, the art of construction in stone. The earliest existing examples are among the most magnificent specimens of the art. No nation has excelled the ancient Egyptians, who did not use mortar in their important structures, such as the pyramids, the joints being all carefully polished and fitted. Cyclopean masonry, of which remains exist in many parts of Greece and Italy, also exhibits stones of great size and with carefully-adjusted joints. The walls of Mycenæ are among the earliest examples. These are built with huge irregular blocks, the spaces between being filled up with smaller stones. The Etruscan specimens are more carefully executed; the stones are not squared, but they are all carefully fitted together. The masonry of the Greeks and Romans very closely resembled that of the present day: *Rubble-work* (*opus incertum*), in which the stones are not regularly coursed; *Coursed-work*, where the joints are all level, and the stones of equal height; *Ashlar*, resembling the latter, but built with larger stones carefully dressed on the joints.

The early medieval masonry was of very bad construction, being, in fact, little better than common rubble, with an occasional use of Herring-bone Work. The Normans improved upon this kind of work, but their masonry was also so bad that many of the towers built by them either fell or had to be taken down. The art gradually improved with the advance of Gothic architecture, and ashlar was re-introduced for all important works. The ashlar-work so constantly used in Renaissance buildings has given place to the hammer-dressed and squared masonry. Special materials sometimes produce special kinds of work; thus, in Norfolk and Suffolk, walls are often faced with large flints, split so as to form a clean face and good joints, in bands or panels between stonework or brickwork.

Masons' Marks, or BANKER MARKS, in mediæval buildings were cut upon each stone by the craftsman who worked it. Each man had his own device, whereby every stone for which he was responsible could be identified.

Masorah, or MASORETH (tradition), a collection of critical notes on the text of the Old Testament, its divisions, accents, vowels, grammatical forms, and letters (see HEBREW LANGUAGE). The

Masorah, like the Halacha and Haggada, was the work of many ages and centuries, as, indeed, we find in ancient authorities mention made of different systems of accentuation used in Tiberias (Palestine), and Babylon (Assyria). It was in Tiberias also that the Masorah was first committed to writing between the 6th and 9th century A.D. Monographs, memorial verses, and glosses on the margins of the text seem to have been the earliest forms of the written Masorah, which gradually expanded into one of the most elaborate and minute systems, laid down in the 'Great Masorah' (about the 9th century), whence an extract was made known under the name of the 'Small Masorah.' The final arrangement of the Masorah, which was first printed in Bomberg's second Rabbinical Bible (Venice, 1525), is due to Jacob ben Chayim of Tunis and to Felix Pratensis (in the Bomberg edition of 1518). The language of the Masoretic writers is Aramaic, and the abbreviations, contractions, symbolical signs, &c., require careful study. Many have been translated and explained by Prof. A. S. Geden (*Massoretic and other Notes*, published by the Brit. and For. Bible Soc., 1906). See Dr Ginsburg's great work on the Masorah (4 vols. folio, 1880-86); L. Blau, in *Jew. Quart. Rev.*, xii. 1900, pp. 217 foll.; S. Baer, *Zeitschr. d. D. Morgenländ. Ges.*, xl. pp. 743 foll.; E. N. Adler, *About Hebrew Manuscripts*, pp. 49 foll.; the art. 'Masorah' in the *Jew. Ency.* The different forms of the term *Masoreth*, *Masorah*, &c., are discussed by W. Bacher, *Jew. Quart. Rev.*, iii. 1891, pp. 785 foll.; and by C. Levias, *Heb. Union Coll. Annual*, 1904.

Masovia. See MASURIANS, POLAND.

Maspero, SIR GASTON CAMILLE CHARLES, K.C.M.G. (1846-1916), Egyptologist, born at Paris of Italian parents, began to lecture on Egyptology at the École des Hautes Études in 1869, and in 1873 was appointed professor of Egyptology at the Collège de France. In 1881 he founded a school of Egyptian archaeology at Cairo, and in 1881-86, and in 1899-1914, was director of explorations and custodian of the Cairo Museum. In 1886 he became professor at the Institute of Paris, in 1914 secretary of the Académie des Inscriptions. As an explorer he excavated or opened the pyramids of the 5th and 6th dynasties, and the burial-places of Sakkara and Dahshûr, and discovered new sepulchral sites of great value at Deir el-Bahari near the entrance to the Valley of the Tombs of the Kings, at Elkhûm 130 miles S. of Thebes, and at other places. He wrote many valuable works on Egyptian archaeology, history, and folklore.

Masque, a species of dramatic performance, much in vogue in England towards the close of the 16th and the beginning of the 17th century. It was in fact the favourite form of private theatricals at the time. The masque appears to have originated in the practice of introducing, in any solemn or festive processions, men wearing masks, who represented imaginary or allegorical personages. At first it was simply an 'acted pageant,' as in the well-known progresses of Queen Elizabeth; but gradually it expanded into a regular dramatic entertainment, and in the hands of men like Fletcher and Ben Jonson attained a high degree of literary beauty. Jonson's masques were represented at court, and were greatly relished. The taste for masques died out under Charles I., to whose reign belongs the noble *Comus* of Milton (1634).

See Brotanek, *Die englische Maskenspiele* (1902); Greg, *List of Masques* (1902); Reyher, *Les Masques anglais* (1909); *The Cambridge English Literature*, vol. vi. (1910); and *Shakespeare's England*, vol. ii. (1916).

Masquerade, or MASKED BALL, a festive meeting in which the host and guests are more or less disguised, the name being derived from the

use of the mask. The public *nummeries* of former times, Easter plays, Festivals of Fools, &c., which were frequent in most parts of Europe, but somewhat various in different countries, probably suggested the idea of the masquerade, which, however, was not open to all, according to the well understood rules of these ancient amusements, but was limited to some select class, or to those who paid a certain sum for admission. Catharine de' Medici introduced the regular masquerade at the French court. It found its way to England in the reign of Henry VIII., but did not reach any of the courts of Germany till the end of the 17th century.

Mass is defined as 'the quantity of matter in a body'; and weight is proportional to mass. See GRAVITATION, MATTER.

Mass. See LITURGY.

Mass, MUSIC OF. Each part of the service of High Mass has its unisonal plain-song melody, varying according to the season or festival; the first collections of these melodies were made by St Ambrose, and afterwards more completely by St Gregory. But since the invention of counterpoint certain portions have been selected for more elaborate treatment—viz. the *Kyrie, Gloria, Credo, Sanctus, Benedictus*, and *Agnus Dei*; each of which, but especially the *Credo*, is by common traditional practice divided into separate movements, also designated by the initiatory words. In the early contrapuntal music, a plain-song melody, or even a secular tune, formed the basis on which the whole was constructed, and the mass was named in accordance—e.g. the numerous *Missa L'Homme Armé*, founded on an old French love-song. This appropriation of secular tunes, which could never wholly lose their association with the often objectionable words, anticipates Shakespeare's Puritan 'who sings Psalms to hornpipes,' and the similar practices of recent revivalists. These compositions soon became more remarkable for their learning and ingenuity than appropriateness or reverential feeling; and to such an extent was this abuse carried that the Council of Trent condemned them in no measured terms, and a commission, appointed in 1564 to carry out certain of its decrees, was on the point of entirely forbidding the use in future of polyphonic music in the church, when the production by Palestrina of his world-famous *Missa Papæ Marcelli* convinced the cardinals that such music could be profoundly devotional as well as technically skilful; and its use was allowed to be continued. The succeeding epoch of church music, however, was one of decline; but in the later part of the 17th and commencement of the 18th century arose a new school, comprising Alessandro Scarlatti, Leo, and Durante, in whose compositions the introduction of instrumental accompaniment was the most important new feature—one which gave to all subsequent masses the style of the cantata, more individual and dramatic than devotional. In this style also are the stupendous masses of Bach in B minor, Beethoven in D, and Cherubini in D and A. Those of Haydn, Mozart, Weber, Schubert, and Gounod are full of beautiful music. Pius X. ordered a return to the Gregorian chant in 1903.

The music of the Requiem, or *Missa pro defunctis*, differs of course considerably in its details from that of the ordinary High Mass. The most famous compositions for it are those of Mozart and Cherubini. Brahms's masterpiece, the German Requiem, is not a mass, but a sacred cantata on scriptural words.

Massa, distinguished as MASSA DI CARRARA, a city of northern Italy, 20 miles by rail S.E. of Spezia. It is a bishop's see, has a public library, an academy of arts and sciences, a cathedral, and a ducal palace. The inhabitants rear silkworms, grow tobacco, press oil, make paper, saw timber,

and trade in the white marble that all sculptors use. Pop. 34,000.—The province of Massa and Carrara has an area of 687 sq. m., and a pop. of 226,000. In 1568 the ruling family in Massa were created princes, and in 1664 dukes. The dukedom passed by marriage to the house of Modena-Este in 1741.

Massa, a port of Morocco, at the mouth of the Wadi Massa, 60 miles S. of Agadir, is popularly reputed to be Jonah's landing-place.

Massa, NICCOLÒ (1499–1569), Italian medical writer, born at Venice.

Massachuset, a tribe or confederacy of Algonquins (q.v.) who inhabited the shores of Massachusetts Bay, and had their chief village on the site of Quincy, Mass. John Eliot (q.v.) undertook their conversion to Christianity, and it was into their tongue that he translated the Bible (1661–63) and other books. They were already dwindling away; and by his policy of associating them in villages with other 'praying Indians' their separate existence was brought to an end.

Massachusetts, one of the New England states of the American Union, lies between 41° 14' and 42° 53' N. lat., and between 69° 53' and 73° 32' W. long., and, 160 miles long by 47 to 90 broad, has an area of about 8300 sq. m.—larger than Wales. It is bounded on the north, west, and south by New Hampshire, Vermont, New York, Connecticut, Rhode Island, and the Atlantic; on the east by Massachusetts Bay, a part of the Atlantic Ocean, from which the state derives its familiar name of the Bay State. The surface is uneven, varying from low plains, near the sea-coast, containing numerous small lakes, to a rolling country in the interior, becoming mountainous as the western boundary is approached. This mountainous portion is composed of two distinct ranges, being part of the Green Mountains, which here extend southward from the adjacent state of Vermont. The highest of the peaks is Greylock (3505 feet), but most of them are wooded to the summit, and the scenery, while not grand, is of great beauty. The soil is in many portions, particularly in the east, rocky and sterile, and the state contains several quarries of importance yielding granite and syenite, red sandstone, and valuable marble. In granite production Massachusetts is one of the most important states in the Union. Other products of value are clay and lime. There is not much mining. The soil of the river-valleys and of some other sections is fertile, the leading products being corn, potatoes, and tobacco. The fisheries are the most important in the Union, a large capital being invested and the annual product large.

The rivers, while not important for navigation, are the source of valuable water-power which has been utilised in industry, and in annual manufacturing output the state leads all others except New York and Pennsylvania. The chief manufactures are textiles, iron and other metallic goods, boots and shoes, food preparations, building materials, clothing, paper and wood-pulp, leather, wooden wares, &c. The leading textile industries are cotton, woollen, and worsted goods. There are 5000 miles of electric and steam railway in the state.

Massachusetts contains fourteen counties, and returns two senators and sixteen representatives to the federal congress. The state legislature is called the General Court of Massachusetts. Its sessions are biennial. The Senate consists of 40, the House of Representatives of 240, members. The executive branch of the government is vested in the governor, who is officially styled the governor of the commonwealth of Massachusetts, and whose title is His Excellency; lieutenant-governor, whose title is His Honour; and an advisory council consisting of eight members chosen by districts. The

governor, lieutenant-governor, and heads of the executive departments are elected annually. The cities of the commonwealth must have a population of at least 12,000. The towns (corporate bodies having less than 12,000 inhabitants) are governed by a board of selectmen elected by popular suffrage in an annual town meeting of all the voters in the town, which meeting also makes appropriations for the maintenance of the different departments of the town government. All judges in the commonwealth are appointed by the governor with the advice and consent of the council, and hold their office during good behaviour. The active military force of the state, the national guard, or organised militia, consists of some 10,000 officers and men. Besides this active militia all able-bodied male citizens between the ages of eighteen and forty-five, except exempt persons, are enrolled, and subject to military duty in time of exigency.

Popular education in Massachusetts, through the system of free public schools, is carried to a very high point. Public primary, grammar, and high schools are supported by taxation—tuition and textbooks being free; and there is a system of university extension teaching under the Advisory Board of Education. Massachusetts maintains ten normal schools, and there are in the state two technical institutes, and fifteen colleges and universities, the latter including Harvard, Williams College, Amherst College, and Boston University and College.

The leading cities of Massachusetts are Boston (pop. in 1920, 748,060), the capital and chief seaport; Worcester (179,754), with manufactures in metals and machinery; Springfield (129,614), with numerous manufactures; Holyoke (60,203), the centre of the paper manufacture; Fall River (120,485), Lowell (112,759), and Lawrence (94,270), devoted to cotton manufacturing; Lynn (99,148), Haverhill (53,884), and Brockton (66,254), boot and shoe centres; Salem (42,529) and New Bedford (121,217), both noted seaports of former days, and now possessing extensive cotton-mills; Taunton (37,137), with varied manufactures; Gloucester (22,947), noted for its fisheries; and Cambridge (109,694), near Boston, the seat of Harvard University; Somerville (93,091), Malden (49,103), Quincy (47,876), Newton (46,054), Pittsfield (41,763), Fitchburg (41,029), and Medford (39,038). Pop. of state (1800) 422,845; (1850) 994,514; (1890) 2,238,943; (1900) 2,805,346; (1910) 3,666,416; (1920) 3,852,356.

History.—The coast is supposed to have been visited by Northmen about the year 1000, but the first permanent settlement was made at Plymouth, near Cape Cod, 22d December 1620, by the company of the Pilgrim Fathers (q.v.), who were separatists from the English Church, and who sailed from Plymouth, England, in the ship *Mayflower*. This settlement became the nucleus of the Plymouth Colony. In 1628 a company of Puritans under Endicott settled at Salem upon the coast farther north, and, with later settlements at Boston, Lynn, and elsewhere, became the Massachusetts Bay Colony. The union of these two colonies was accomplished under a new charter granted in 1692. Under this last charter the governor, lieutenant-governor, and secretary were appointed by the king. Prior to this none but the Puritan forms of religion had been permitted in the colony of Massachusetts, and its history had been marked by bitter intolerance and cruel persecutions. Now a system was adopted under which the majority of each town or parish chose the minister, who was maintained by the taxes paid by all alike. No consideration was shown to the minorities, and the old Puritan establishment was virtually continued nearly everywhere. The last vestiges of this union between church and state were not swept away until 1833.

During the early years the colonists suffered great privations from the rigours of the climate, and they were also subjected to troubles with the Indians. They were, however, a hardy and industrious race, and gradually grew in numbers and prosperity. They were involved in the difficulties between England and France in the New World, and in the expeditions against the French in Canada, especially at the first siege of Louisburg (q.v.), the citizen soldiers of Massachusetts performed effective service. After the war of the revolution, begun in Massachusetts in 1776 with the battles at Lexington and Bunker Hill, the colony became one of the original thirteen states of the Union, under the name of the commonwealth of Massachusetts. The second half of the 19th century witnessed the change of Massachusetts from a largely agricultural to a manufacturing state, and now a majority of the population is urban; not because less land is cultivated, but because manufactures have increased much faster than agriculture.

See Hale, *Story of Massachusetts* (1892); Adams, *Massachusetts, its Historians and History* (1893).

Massa e Carrara, an Italian province. See MASSA.

Massafra, a town of the Italian province of Lecce, 11 miles NW. of Taranto. The 11,000 inhabitants grow olives, wine, and fruits.

Massage (Fr., 'kneading') is the term used in medicine to denote a system of treatment in which the manipulation and exercise of parts ('passive movement') are employed for the relief of morbid conditions. The term is used in an elastic sense, and comprises a variety of forms of treatment extending in the one direction towards the composite gymnastic exercises of Swedish origin (see SLOYD), so useful in favouring a sound physical development in children, and in the other towards the jerking and wrenching movements, empirically employed, and familiar in Great Britain under the name of 'bonesetting.' For the most part, however, massage corresponds to the application of kneading, stroking, and rubbing, separately or combined with each other.

Massage is as old as, if not older than, any other form of medical treatment. Hippocrates (600 B.C.), the 'Father of Medicine,' has left in his writings a description of its application and uses; observing that 'it loosens stiff joints and gives tone and strength to those which are relaxed; further, that 'it must be applied with soft hands and in all cases delicately.' In the Greek world, and also in the Roman (cf. Lytton's *Last Days of Pompeii*), massage formed a necessary complement to the toilet of the bath; but, apart from the slaves who were specially trained for such duties, there appears to have been a regular profession of 'rubbers' competing with, and often superseding the physicians of the period. The Chinese and the early races of India seem to have known the value of massage from a remote period, for it is frequently referred to in the ancient writings of both peoples. During the dark ages this method of treatment seems to have fallen into disrepute in Europe; and it was only within the later half of the 19th century that its practice was thoroughly re-established, and that on a scientific basis. It is largely due to Dr Mezger, a physician of Amsterdam, that massage has become once more a systematised mode of medical treatment. He began to treat sprains by this method in 1853, and from that time to the present his system has attracted much attention, and has spread widely over the European and American continents.

Two chief methods of application are employed: (1) Stroking, or rubbing with a gliding movement, affecting chiefly the superficial parts (*effleurage*). (2) Pressing, tapping, or kneading, affecting chiefly the deeper tissues, and in one locality at a time (*tapotement*). To these may be added an important combination of the two, viz.: (3) Friction with kneading (*pétrissage*), in which the tissues are at the same time rubbed longitudinally and squeezed laterally, both superficial and deeper tissues being thereby equally affected. In applying these methods the hand and fingers of the manipulator alone are used. As a rule, if the hands are soft and moist no emollient substance is required, and the best effects are produced without such aid. In all cases the movements follow a direction towards the trunk. In stroking (*effleurage*) the finger-tips pass first lightly over the affected surface, followed by the outspread palm of the hand, which exerts a slightly firmer pressure. In tapping (*tapotement*) the finger-tips, the knuckles, or the edges of the palm are firmly thrust against the affected areas, so as to act chiefly on the deeper tissues, by compressing them firmly against the bony framework of the part. In friction (*pétrissage*) the tissues are grasped and raised between the fingers and thumbs, and slightly compressed laterally as well as longitudinally as the manipulator's hands pass upwards over the part. The total time taken up in the application of one of these methods, or in a combination of any of them, should not exceed twenty minutes, and as a rule one such *séance* is sufficient in the twenty-four hours. An hour's rest should be taken after each *séance*.

The chief vital effects produced by massage are soothing of pain by reduction of the sensibility of the nerves of the skin; an acceleration in the circulation both of blood and lymph in the parts operated on; and, as a result, increased nutrition of healthy tissues and accelerated removal of morbid products. General and local applications of massage are practised in medicine—the former when some general effect is aimed at, as in nervous emaciation, and in the treatment of the apparently drowned; the latter in local injuries, as sprains and bruises, and in local manifestations of constitutional conditions, as rheumatic joint affections, neuralgia, tic, and sciatica. In purely local joint and bone diseases, while an active process of disease is present, it is, however, likely to do harm.

Massa'getæ, a wild and warlike people, who inhabited the broad steppes on the north-east of the Caspian Sea, to the northward of the river Araxes or Jaxartes. Herodotus says that they had a community of wives; that they sacrificed and devoured their aged people; that they worshipped the sun, and offered horses to him; that they lived on the milk and flesh of their herds, and on fish; that they fought on horseback and on foot with lance, bow, and double-edged axe. Cyrus is said to have lost his life in fighting against them, 530 B.C.

Massalia. See MARSEILLES.

Masséna, ANDRÉ, Duke of Rivoli, Prince of Essling, and the greatest of all Napoleon's marshals, was born at Nice, it is said of Jewish origin, 6th May 1758. He began life as a cabin-boy, and served fourteen years in the Sardinian army, but left it because his plebeian birth precluded him from promotion. Early in the French Revolution he joined a battalion of volunteers, and rose rapidly in rank, becoming in December 1793 a general of division. He distinguished himself greatly in the campaigns in Upper Italy, especially at Saorgio (1794), Loano (1795), and Rivoli (1797), and earned from his chief his famous surname of

enfant chéri de la victoire. After Jourdan's defeat at Stockach (25th March 1799) the chief command of the army in Switzerland devolved upon him in circumstances of great difficulty, but he kept his ground against the Archduke Charles, and finally by his crushing victory over Suvaroff at Zürich (1799) freed France from the danger of invasion. He defended Genoa in 1800. In 1804 Napoleon made him a marshal of the empire, and next gave him the command of the army of Italy. He kept the Archduke Charles in check, crushed him at Caldiero, and overran Naples. In 1807, after the battle of Eylau, he commanded the right wing of the French army, and at the end of the campaign was created Duke of Rivoli. During the peace he lost his left eye by accident at a hunting-party. In the campaign of 1809 against Austria he commanded on the right bank of the Danube, and covered himself with glory at Landslut, Eckmühl, and Ebersberg-on-Traun. On the second day of the battle at Aspern or Essling (22d May), with the most conspicuous bravery he covered the army in its crossing the Danube, and alone saved it from destruction, earning for himself the title of Prince of Essling. In 1810 he was sent to Spain to drive the English into the sea, and he compelled Wellington to fall back upon his impregnable lines at Torres Vedras. Finding it impossible to obtain any advantage, and harassed by lack of supplies, he made a masterly retreat, to find himself recalled with ignominy by his imperious master. His failure he himself ascribed to the disobedience of his subordinates, Ney and Junot. He offered his services, however, again, when Napoleon was preparing for the Russian campaign, but was entrusted only with the command in Provence, and in this position he remained till the Restoration, when he gave in his adhesion to the Bourbons, and was made a peer. On Napoleon's return from Elba he invited Masséna to follow him, but received no response. He refused to sit on Ney's court-martial, and denounced the competence of the court. He died 4th April 1817, and was buried in Pere-la-Chaise with the one word *Masséna* on his tombstone. In tactics Masséna resembled his master in quickness and fertility in resource. He was brave and indefatigable in the field, but as extortionate as a Roman prætor. His *Mémoires* were edited by General Kock (7 vols. 1849-50), and there is a *Life* by Toselli (1869). See Gachot, *Histoire militaire de Masséna* (1901 et seq.).

Massenet, JULES (1842-1912), composer, born at Montaud, near St Etienne, studied under Ambroise Thomas, and was professor of Composition at the Paris Conservatoire in 1878-96. He won the *Prix de Rome* in 1863, was favourably received as the composer of meritorious orchestral works and a comic opera, *La Grande Tante* (1867), and in 1873 took his place amongst the foremost of the younger composers of France, his fame being established by the comic opera *Don César de Bazan* (1872), the classical opera *Les Érinnyes* (1873), and the oratorio *Marie Madeleine* (1873). These were followed by the oratorios *Eve* (1875) and *La Vierge* (1879), the operas *Roi de Lahore* (1877), *Hérodiade* (1881), *Manon Lescaut* (1884), *Esclarmonde* (1889), *Thais* (1894), *Le Jongleur de Notre Dame* (1902), *Roma* (1912), *Cléopâtre* (1914), and others, and numerous instrumental pieces.

Massey, WILLIAM FERGUSON (1856-1925), New Zealand statesman, was born of Ulster stock at Limavady, near Londonderry. In 1870, when fourteen years of age, he went to New Zealand to rejoin his parents, who in 1862 had emigrated, and, having worked for a time on the land with his father, eventually settled at Mangere, near Auckland,

and became a prosperous farmer. Following varied experience in local government, he was in 1894 elected to parliament as Conservative member for Waitemata. In 1903 he became leader of his party, and in 1912, after eighteen years of opposition, prime minister in a Reform—this name had now been adopted by the Conservative party—government; this office he held till his death, from 1915 to 1919 in a Reform-Liberal coalition. Massey's chief work lay in his restoration of the fortunes of his party, in his procuring for Britain the complete support of New Zealand during the Great War, and in his efforts after the war to bring a return to normal conditions.

Massillon, JEAN BAPTISTE, one of the most distinguished of modern orators, was born at Hyères in Provence, 24th June 1663. His father was a notary and had designed him for his own profession, but at length in 1681 the boy obtained permission to follow his vocation and enter the congregation of the Oratory. Later, he subjected himself to a more rigorous discipline in the abbey of Sept-Fonts. His preaching power was soon discovered, and his funeral oration on M. Villars, the Archbishop of Vienne, established his fame, and led to his being summoned by Cardinal de Noailles to Paris, where he first had the opportunity of hearing Bourdaloue, whose style and manner powerfully influenced the young orator. It is said that the older preacher said when first he heard him, 'He must increase, but I must decrease.' Like Bourdaloue, he avoided the declamatory manner and theatrical action then popular in the French pulpit; and the earnest impressiveness of his face and voice more than counterbalanced the lack of such adventitious aids to effect. He gave a remarkable series of lectures in the seminary of St Magloire, and first preached before Louis XIV. in Advent 1699. It was to him that the king said, 'I have heard great orators in my chapel and have felt satisfied with them, but every time I have heard you I have felt dissatisfied with myself'—a saying which well expresses the characteristics of the fearless eloquence of this great orator, who, more than any of his contemporaries, was able to lay bare the secret springs of human action, and to use the feelings and the passions of his audience as arms against themselves. He was again appointed to preach the Lent at Versailles in 1704; but although the king was again equally warm in his admiration, Massillon was never afterwards invited to preach in his presence. In 1717 Massillon was named Bishop of Clermont, and next year preached before the young king, Louis XV., his celebrated *Petit Carême*—a series of ten short Lenten sermons. It was not till 1719 that he was consecrated Bishop of Clermont, in which year also he was elected a member of the Academy; and in 1723 he preached the funeral oration of the Duchess of Orleans, his last public discourse in Paris. From this time he lived almost entirely for his diocese, where his charity and gentleness gained him the love of all. He died of apoplexy, 28th September 1742. Bossuet and Bourdaloue contest with Massillon the palm of oratory, yet it is not too much to say that he was a greater preacher than either. By French critics he has been termed the Racine of the pulpit, and the name may pass as regards the purity and elegance of Massillon's language, though it takes no count of his characteristic directness and vigour. For impassioned denunciation of vice marks his preaching, no less than gentle persuasiveness to virtue, although it remains true that he is greatest in the latter. His sermons on the Prodigal Son, on the Deaths of the Just and the Unjust, for Christmas, and for the Fourth Sunday in Advent may be named among his masterpieces.

His sermons were collected by his nephew (15 vols. 1745-48); later editions are those of Renouard (1810), the Abbé Guillon (16 vols. 1828), and Blampignon (4 vols. 1886). See Sainte-Beuve's *Causeries du Lundi*, vol. ix.

Massinger, PHILIP, dramatist, baptised at St Thomas's, Salisbury, 24th November 1583, was a son of Arthur Massinger, a retainer of the Earl of Pembroke. In a dedicatory epistle to Philip Herbert, Earl of Montgomery, prefixed to *The Bondman* (1624), he mentions that his father spent many years in the service of the Herbert family, 'and died a servant to it.' On 14th May 1602 Massinger entered St Alban's Hall, Oxford, and he left the university without a degree in 1606. Gifford supposed that during his residence at Oxford he became a convert to the Roman Catholic faith; and the plays afford some evidence in support of this view.

Massinger was writing for the theatre during the lifetime of the stage-manager Philip Henslowe, who died in January 1615-16. At Dulwich College is preserved an undated letter (*circa* 1613-14) to Henslowe from Nathaniel Field, Daborn, and Massinger. The three playwrights were in financial distress and begged for an advance of five pounds ('without which we cannot be bailed') on a play which they were preparing. Their petition was granted. On 4th July 1615 Daborn and Massinger borrowed from Henslowe the sum of three pounds. In later years Massinger wrote many plays single-handed; but much of his work is mixed up with the work of other men, particularly Fletcher. His friend Sir Aston Cokayne, in an 'Epitaph on Mr John Fletcher and Mr Philip Massinger,' expressly states, 'Plays they did write together, were great friends.' Beaumont had a share in only a few of the plays ascribed to 'Beaumont and Fletcher;' but Massinger and Fletcher continued to work together long after Beaumont's death. Fletcher was buried in St Saviour's Church, Southwark, 29th August 1625; and Massinger was laid in the same grave, 18th March 1640.

Probably the earliest of Massinger's extant plays is *The Unnatural Combat*, a repulsive tragedy, printed in 1639. The first in order of publication is *The Virgin Martyr* (1622), partly written by Dekker, who doubtless contributed the beautiful colloquy between Dorothea and Angelo (II. i.). In 1623 was published *The Duke of Milan*, a fine tragedy, but too rhetorical. *The Bondman*, *The Renegado*, and *The Parliament of Love* were licensed for the stage between 3d December 1623 and 3d November 1624. In many of his plays Massinger introduces political allusions, and more than once his temerity was rebuked by Sir Henry Herbert, Master of the Revels. *The Bondman* contains some outspoken criticism on the feeble condition of the navy. There is considerable resemblance between *The Parliament of Love*, which was first printed by Gifford from a mutilated MS., and *A Cure for a Cuckold*, ascribed to Webster and Rowley (but not improbably the work of Massinger and Rowley). Of *The Roman Actor*, produced in 1626 and printed in 1629, Massinger declares 'I ever held it the most perfect birth of my Minerva.' It abounds in eloquent declamation, but is somewhat stiff. *The Great Duke of Florence*, produced on 5th July 1627, has a delightful love-story. Massinger's female characters are usually unattractive and sometimes odious; but in this comedy he has drawn a charming heroine—a modest, frank, warm-hearted girl. *The Maid of Honour*, published in 1632 and probably produced in 1628, is—like *The Bondman*—full of political allusions (as S. R. Gardiner showed). Massinger is always opposed to the court faction. *The Picture*, licensed for the stage 8th June 1629, and printed in 1630, has an improbable plot, but

is well written. *The Emperor of the East*, produced in 1631 and printed in 1632, bears some resemblance to *The Duke of Milan*. In both plays a man of passionate, ungovernable temper unjustly suspects his wife of infidelity; but *The Emperor of the East* ends happily. Nathaniel Field joined Massinger in writing the fine tragedy *The Fatal Dowry*, printed in 1632, but produced some years earlier. From this play Rowe's once-famous *Fair Penitent* was largely drawn, without acknowledgment. *The City Madam*, licensed for the stage in 1632, and *A New Way to pay Old Debts*, printed in 1633, are Massinger's most masterly comedies. There is no warmth or geniality about them; but, as satirical studies, they have Ben Jonson's strength without his ponderousness. *A New Way* has held the stage down to recent times. Sir Giles Mompesson, the infamous extortioner, is supposed to have been the original of Sir Giles Overreach, a character which has been personated by many famous actors. *The Guardian* (1633), *A Very Woman* (1634), and *The Bashful Lover* (1636) were printed together, 1 vol., in 1655. The most interesting is *A Very Woman*, which is Fletcher's play *The Woman's Plot* revised by Massinger. *Believe as You List*, produced on 7th May 1631, and first printed from MS. in 1844, relates to the adventurer who at the beginning of the 17th century claimed to be the Don Sebastian killed in 1578 at the battle of Alcazar. Massinger represents the claimant as a model of kingly dignity, worthy to rank with Ford's Perkin Warbeck. Though *Believe as You List* has survived, several other MS. plays of Massinger were destroyed by Warburton's cook towards the close of the 18th century. The powerful and stately *Tragedy of Sir John Van Olden Barnavelt*, produced in August 1619, written by Massinger and Fletcher, was printed for the first time from MS. in vol. ii. of Bullen's *Old Plays* (First Series), and was reprinted in Holland. In spite of the Lord Mayor's prohibition it was acted with applause by the king's men.

Massinger showed great care and skill in the construction of his plays. Other playwrights affect us more powerfully, but few can compare with Massinger for general excellence. He was not only a sincere, high-minded artist, but a keen observer of state affairs. Hence his writings have a historical as well as a literary interest. Some of his plays are (as Coleridge said) as interesting as a novel; others are as solid as a treatise on political philosophy. His versification is peculiar. He seems to have taken the metrical style of Shakespeare's latest plays as his model; but his verse, though it is fluent and flexible, lacks the music and magic of Shakespeare's. No writer repeats himself more frequently than Massinger; he had a set of favourite phrases that he constantly introduces. This trick of repetition, joined to his metrical mannerisms, helps us materially to distinguish his work from Fletcher's. Robert Boyle (in *Englische Studien*) and F. G. Fleay have discussed the difficult question how far Massinger was concerned in the authorship of plays that pass under the name of 'Beaumont and Fletcher.'

Massinger's plays were edited by William Gifford in 1805, 4 vols.; 2d ed. 1813. There are also editions by Hartley Coleridge (1840) and (from the text of Gifford) by Cunningham (1867). See also Koeppl in *The Cambridge English Literature* (vol. vi. 1910), essays by Swinburne and Leslie Stephen, and Cruickshank's study (1920).

Massinissa. See MASINISSA.

Masson, DAVID, an eminent Scottish author, born at Aberdeen, 2d December 1822, educated at Marischal College in that city, and at the university of Edinburgh. At nineteen he became editor of a Scottish provincial paper, and later joined the

literary staff of W. & R. Chambers. In 1847 he settled in London, writing for the reviews, the *Encyclopædia Britannica*, and the *English Encyclopædia*. In 1852 he succeeded Clough in the chair of English Literature in University College; in 1865 he became professor of English Literature in the university of Edinburgh, a post he resigned in 1895. Masson edited *Macmillan's Magazine* from 1859 to 1868. His first published work was his *Essays Biographical and Critical* (1856), reprinted with later essays in 3 vols. (1874-76) entitled respectively *Wordsworth, Shelley, and Keats*; *The Three Devils—Luther's, Milton's, and Goethe's*; and *Chatterton, a Story of the Year 1770*. His great work is his ponderous *Life of John Milton, narrated in connection with the Political, Ecclesiastical, and Literary History of his Time* (6 vols. 1859-80), the most complete biography of any Englishman, and of great value for contemporary history. Other works are *British Novelists and their Styles* (1859); *Recent British Philosophy* (1865); *Drummond of Hawthornden: the Story of his Life and Writings* (1873); the 'Cambridge' edition of *Milton*, with introductions, notes, and an essay on Milton's English (3 vols. 1874; new ed. 1890), the 'Golden Treasury' edition (2 vols. 1874), and the 'Globe' edition (1877). Later works are *De Quincey* (1878) in the 'Men of Letters' series, and his edition of De Quincey's works (14 vols. 1889-91), some volumes of *Sketches and Essays* (1892 and 1894), *Memories of Two Cities* (1911), and *Shakespeare Personally* (1911). In 1879-98 he edited the *Register* of the Privy Council of Scotland, and from 1893 till his death, 6th October 1907, he was Historiographer Royal for Scotland.

Massorah. See MASORAH.

Massowah, or MASSAUWA, a town built on a coral island off the west coast of the Red Sea, in 15° 36' N. lat., 39° 28' E. long. It was seized by Turkey in 1557, but in 1866 given by her to Egypt; and in 1885 it was occupied by Italy. The island is only about 1½ mile in circumference, and is connected with the mainland by a causeway, 1610 yards in length, resting on an intervening island. The population number about 7000 (exclusive of the garrison), of whom 200 are European, mainly Italian. Fishing for pearls and mother-of-pearl is the principal industry, but there is also a little fishing, and weaving of palm-fibres. Massowah is one of the most important harbours and trading-ports on the African coast of the Red Sea, and its trade is mainly with Arabian ports, Bombay, Suez, and Abyssinia. It is the terminus of a military railway into the interior. The chief exports are pearls and mother-of-pearl, ivory, ostrich feathers, coffee, tobacco, wax, precious stones, gold, and skins. Massowah is very hot (mean of the year 85° 8' F.) and very unhealthy; nevertheless the advantages of its site led the Italians to make it the capital of Eritrea. It was superseded by Asmara in 1900.

Massys. See MATSYS.

Master. See COURTESY TITLES.

Master, in the royal navy, was an officer ranking with, but junior to, lieutenants, and charged with the details of sailing the vessel, under the general orders of the captain. Now the title has been changed to 'navigating lieutenant.' In the merchant navy the master of a vessel, usually, by courtesy, denominated the captain, is the officer commanding her.

Master and Servant. The relation of master and servant arises out of a contract of hiring and service. Under such a contract one person agrees for a wage or other valuable consideration to work subject to the orders of another. The contract may be express or inferred from

conduct. Under a contract of service the employer has a right not only to direct what work the servant is to do but also the manner in which the work is to be done. The relation of master and servant exists only between persons of whom the one has the order and control of the work done by the other. This is the main test to be applied in determining whether a contract, involving the performance of work or the rendering of services, does or does not constitute the relation of master and servant.

A contract of hiring and service, either as master or servant, may be entered into by any person of ordinary contractual capacity. The contract of an infant to serve or do work for another is presumed to be for the infant's benefit, and is therefore *prima facie* binding on him. The fact that the contract includes some stipulations which, taken by themselves, are not beneficial from the infant's point of view will not render it unenforceable against him if the conditions agreed on, taken as a whole, are not unfair or detrimental to him.

The consideration for a contract of service is, as a rule, an agreed sum to be paid in wages. (As to preferential claims for wages on the bankruptcy of the employer, see BANKRUPTCY.) Wages or other remuneration for services can only be recovered when it can be shown that there was a contract, express or implied, that payment should be made. The mere fact that services are performed or work done for another does not infer that remuneration is payable therefor. A contract of service normally contains terms dealing with the services to be rendered and the wages to be paid. But in many such contracts there are no express stipulations as to either the services or the wages, the parties being content to rely on certain trade customs or usages as imported into the contract. The wages of workmen in industrial employments may be calculated upon the time worked, 'time rates,' or the work done, 'piece rates.' In some trades wages are regulated by sliding-scale agreements. When remuneration is due for work done, but there is no special agreement as to its amount, the person employed is entitled to receive a reasonable reward for his services. In such cases, where a certain rate of remuneration is customary for the particular kind of work done, that rate is taken to be reasonable. The remuneration of a servant may consist, in whole or in part, of a share in the profits of a business. The Partnership Act, 1890, sect. 2, expressly provides that a contract for the remuneration of the servant or agent of a person engaged in a business by a share in the profits of the business does not of itself make the servant or agent a partner in the business or liable as such.

Under the Truck Acts, 1831 to 1896, the wages of workmen—that is, broadly speaking, persons engaged in manual labour other than menial or domestic servants—must be paid in lawful current coin, and not in goods or otherwise. Stipulations that the workmen shall spend his wages in any particular manner or at any particular shop are prohibited. The Acts also contain provisions designed to prevent unreasonable deductions being made from the wages of workmen in respect of fines or damaged tools and materials. (See TRUCK SYSTEM.) By statute (46 and 47 Vict. chap. 31) the payment of wages to any workman, within the meaning of that term in the Truck Acts, at or within any public-house or place for the sale of spirituous liquors is prohibited, unless paid by the resident owner or occupier himself to persons *bona fide* employed by him.

The servant must enter upon his service and continue it for the time agreed. He must serve his master faithfully, obey lawful orders, and

exercise reasonable care and skill. The master on his part must receive the servant into his service and retain him as his servant for the time agreed. He must pay the servant his wages and perform any other obligations undertaken to the servant under the contract. The master is bound to indemnify the servant for all expense, loss, or liability incurred by the servant in obeying the master's lawful orders or in doing, by the master's authority or in the reasonable performance of the duties of the employment, any act which is not plainly unlawful. On the other hand, a servant is not entitled to be indemnified against the consequences of his own unlawful act. Where, however, the act done by the servant was one which was not obviously unlawful and which the servant was induced by his master's conduct to believe to be lawful, the servant will not be deprived of his right to indemnity by reason of the act turning out to have been unlawful. A master is not bound to give his servant or former servant a testimonial or 'character' on leaving his employment, or to answer inquiries by persons who are thinking of taking him into their service. But if, in doing so, he uses words which are *prima facie* a slander or a libel upon the servant, the occasion is one of qualified privilege, and the servant can only recover damages for the slander or libel on proving that the statement was made maliciously (see CHARACTER TO SERVANT).

The duration of a contract of service is fixed by the agreement of the parties or by usage. Where the contract is for a period of a year or less it may be made orally. Where it is for a longer period than a year, or for a year which is to commence on a date subsequent to the date of the making of the contract, it is not enforceable by action unless it is in writing. If a contract of service is entered into without any definite time being expressed or implied for its duration the hiring is considered a general hiring, and is presumed in law to be a hiring for a year; but this presumption may be rebutted by stipulations or other circumstances showing a contrary intention. Where the only circumstance from which the intended duration can be inferred is the reservation of wages at so much a week or so much a month, it is presumed to be a weekly or monthly hiring; but the mere fact of wages being payable weekly or monthly is not conclusive as to the duration of the hiring or inconsistent with a yearly hiring.

A contract of employment may be terminated by either party giving due notice to the other. The length of notice may be provided for in the contract or may be implied from custom or trade usage. In the case of domestic and menial servants, their engagement is determinable by a month's notice on either side; and the master may determine it at any time on paying or tendering a month's wages in lieu of notice. The courts have also taken judicial notice of a custom in domestic service that the service may be terminated at the end of the first month by notice given at or before the end of the first fortnight. The custom of one month's notice does not in general apply to industrial workmen. Where there is no stipulation as to notice and no custom as to notice exists in the trade or employment, the contract is terminable by reasonable notice—the question of what is reasonable notice in particular cases being one of fact, dependent on the nature of the service and the circumstances of the case. The master is justified in terminating a contract of service by dismissing the servant without notice or compensation if the servant wilfully disobeys any lawful order of the master, or is grossly insolent, or is guilty of misconduct inconsistent with the fulfilment of the express or implied conditions of his service, or

habitually neglects his duties or proves to be incompetent for the duties which he undertook. Similarly, the servant is justified in terminating his engagement if the master fails to carry out his part of the contract. A contract of service is conditional upon the servant's health continuing to be such that he can perform his duties. A temporary illness of the servant does not put an end to the contract; but if the servant's incapacity through illness is likely to be permanent, or to last so long that, having regard to the nature of the employment and the length of the term for which the agreement was made, it would be unreasonable to expect the master to keep the servant, the master is entitled to terminate the contract and dismiss the servant. Until the contract is brought to an end the master must continue to pay the servant the full remuneration due to him under the contract.

If either the master or the servant commits a breach of the contract, the other party to the contract is entitled to recover damages. Where a servant is wrongfully dismissed he can recover from his master such damages as will compensate him for the loss which he has actually sustained, including the amount of wages earned but not paid at the date of his dismissal, and the pecuniary loss resulting from his being prevented, by the master's breach of contract, from earning prospective wages under the contract. A domestic servant, on being wrongfully dismissed, can recover a month's wages in addition to wages already due, if any. He, as a rule, is not entitled to recover 'board wages'—i.e. compensation for loss of board and lodging; but where he has been wrongfully dismissed during the currency of a month's notice given by him to terminate the service he is entitled to receive, in addition to ordinary wages, 'board wages' during the period between the date of the wrongful dismissal and the date when the service would have terminated under the notice. Where it is clearly within the contemplation of the parties to the contract that the servant should be at liberty to receive 'tips,' the servant is entitled to claim, as part of the loss sustained by him, an amount in respect of the loss of the tips which he would have received but for the wrongful dismissal. A servant wrongfully dismissed must make reasonable efforts to obtain other suitable employment so that the loss resulting to him from the wrongful dismissal may be diminished. An unreasonable refusal on his part to accept other employment will have the effect of reducing the damages he can recover. It is now settled that the damages recoverable by a servant for wrongful dismissal cannot include compensation for the manner of dismissal or for his injured feelings or for the loss he may sustain from the fact that his having been dismissed of itself makes it more difficult for him to obtain fresh employment. In an action for wrongful dismissal it is a sufficient defence if the master can show that a good ground for dismissal did in fact exist at the time of the dismissal, even though the master may have alleged another ground of dismissal or may have been unaware that such ground of dismissal existed.

A person who knowingly and designedly interrupts the relation subsisting between master and servant by procuring the servant to depart from the master's service or by harbouring and keeping him as servant after he has quitted his place and during the stipulated period of service, whereby his master is injured, commits a wrongful act, for which he is responsible in damages. But the Trade Disputes Act, 1906, sect. 3, enacts that an act done by a person in contemplation or furtherance of a trade dispute shall not be actionable on the ground only that it induces some other person to break a contract

of employment or that it is an interference with the trade, business, or employment of some other person.

A master is liable to third persons upon a contract entered into by his servant where he has expressly authorised the servant to make the contract. He is not, as a general rule, liable upon contracts made by his servant without express authority; but the servant's authority to bind his master may be implied from the circumstances of the case. Thus, a servant may bind his employer by contract if the duties of his employment are such that it is necessary and customary to make contracts of the kind in question in order to enable him to perform these duties, or if the master has previously held him out to third persons as having authority to bind him.

A master is civilly responsible to third persons for the negligence or wrongful act of his servant committed in the course of his employment. This responsibility is founded on the principle that every man in the management of his own affairs, whether by himself or by his agents or servants, is bound so to conduct them as not to injure another. The master, having the right to choose his servants and to control the manner in which they do their work, is responsible not merely for what he authorises his servant to do but also for the way which the servant does it. Hence a wrongful act or omission of a servant is deemed to be done in the course of his employment and renders his master liable to third parties, not only if it has been authorised by the master but also if it be a wrongful, negligent, or unauthorised way of carrying on the work in which the servant is employed or of doing what he was authorised to do. The fact that the wrongful act of the servant had been forbidden by the master does not afford a defence to the master if the act was a mode of doing what the servant was employed to do. The liability of a master extends even to a wilful wrong, such as fraud or assault, committed without the master's knowledge, by the servant in the course of his service. It was formerly thought that where the fraud or other wilful wrongdoing of the servant was committed for his own benefit and not in the master's behalf the master was not responsible. But it is now settled that, if the servant was acting within the scope of his employment, his employer is liable for fraud or other wilful wrong committed by the servant even if the servant's sole intention was to benefit himself. On the other hand, the master is not liable for the acts of his servant outwith the scope of the servant's employment unless he has expressly authorised them or has subsequently adopted them for his own use and benefit. A master is not, generally speaking, criminally responsible for the acts of his servant unless he has himself authorised them. But under certain statutes the master is made criminally liable for acts done by the servant in the course of his employment, although he was unaware of what the servant had done. Thus, under the Licensing Act, 1910, a publican is liable for the conduct of his servants if they supply refreshments to a constable on duty or if they permit gaming to be carried on upon the licensed premises.

A master—as the law stood prior to the Employers' Liability Act, 1880, and the Workmen's Compensation Act, 1897—was not liable for the wrongful act or omission of his servant if the person injured was himself a fellow-servant of that servant. For the rule of common law was and, independently of the statutory law on the subject, is that, in such a case, the employer can set up the defence of 'common employment'—a defence based on the doctrine that a servant, when he engages to serve a master, undertakes, as between himself and his master, to accept all the ordinary risks of the service, including

the risk of negligence upon the part of a fellow-servant. All persons engaged under the same employer for the purposes of the same business are fellow-servants in a common employment within the meaning of this common-law rule. It makes no difference if the servant by whose negligence another servant is injured is a foreman or manager in the same employment, whose orders the injured servant was bound to obey. A workman who has been injured in the course of his employment can at common law recover compensation from his employer only where it is shown that the employer has been guilty of personal negligence or has not provided competent fellow-servants, or has failed to supply safe and proper machinery.

The rule of common law that a master is liable to any person not in his employment for the negligence of his servant but is not liable for such negligence where the person injured is in his employment frequently bore harshly on workmen who had sustained personal injuries in the course of their service. The Employers' Liability Act, 1880 (43 and 44 Vict. chap. 42), was passed for the purpose of mitigating this harshness. The statute, while it does not abrogate the doctrine of common employment, has greatly modified its application, and has gone far to do away with the distinction, as regards a master's liability for the negligence of his servant, between the position of a workman injured in the course of his employment and that of a person who, not being in the master's employment, has been injured. For the general effect of the statute, in cases to which it applies, is to extend to a workman injured in the course of his employment the same rights and remedies against the employer as if the workman had not been in the service of that employer. The workmen entitled to the benefit of the Act are railway servants and persons engaged in manual labour under a contract with an employer (as defined in the Employers and Workmen Act, 1875, *vide infra*, p. 82) other than domestic or menial servants and seamen. An employer is made liable in damages for personal injury to a workman caused by: (1) any defect in the condition of the ways, works, machinery or plant, provided that the defect arises from, or has not been discovered or remedied owing to, the negligence of the employer or of some person in his service entrusted by him with the duty of seeing that these things are in proper condition; (2) negligent superintendence on the part of any servant whose sole or principal duty is that of superintendence and who is not ordinarily engaged in manual labour; (3) the negligence of any servant to whose orders the workman injured was, at the time of the injury, bound to conform, where the injury resulted from his having so conformed; (4) the act or omission of any servant done or made in obedience to the rules or bye-laws of the employer, or in obedience to particular instructions given by any person delegated with the authority of the employer in that behalf, where the injury results from some impropriety or defect in the rules, bye-laws, or instructions; (5) the negligence of a servant having the charge or control of any signal, points, locomotive-engine, or train upon a railway. The workman injured cannot recover if he knew of the defect or negligence which caused his injury and did not, within a reasonable time, inform the employer or some one superior to himself in the service, unless he was aware that the employer or such superior already knew of the defect or negligence. The amount of damages recoverable under the Act is limited to a sum equal to the estimated earnings of a person in the grade, employment, and district of the workman injured during the three years preceding the injury. Notice of the injury must be given to the employer

within six weeks. The action must be commenced within six weeks from the time of the injury, or, in case of death, within twelve months from the time of death. In case of death the want of notice is no bar to the maintenance of the action if the judge thinks there was reasonable ground for such want of notice.

The Workmen's Compensation Act, 1897, now superseded by the Act of 1906 as amended by the Act of 1923, introduced a wholly new principle under which employers, in cases covered by the Acts, are in effect made the insurers of their workmen against accidental injury arising out of and in the course of the workman's employment. The obligation of compensation under these statutes is independent of any negligence on the part of the employer or the fellow-servants of the workman, and is made part of every contract of employment to which the statutes apply. The definition of 'workman' under the Acts is very comprehensive. Under sect. 13 of the Act of 1906 it includes any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implied, is oral or in writing. Section 7 of the Act of 1906 expressly provides that the Act shall, subject to certain modifications, apply to persons employed as members of the crew of any British ship. Under sect. 9 of the Act of 1923 the definition of 'workman' is further extended to include persons engaged in plying for hire with vehicles or vessels the use of which is obtained from the owner under a contract of bailment or, in Scotland, a contract of letting to hire; professional players engaged or paid through a club; and persons, not being members of the crew, engaged for certain purposes on board ship. The cardinal test is that the relation of master and servant must exist between the person against whom the claim is made and the person who makes the claim. Certain classes of persons, however, are expressly excluded: (1) Persons employed otherwise than by way of manual labour whose remuneration exceeds £350 a year; (2) persons whose employment is of a casual nature and who are employed otherwise than for the purposes of the employer's trade or business; (3) members of the police force; (4) outworkers to whom articles are given out to be made up, cleaned, washed, or repaired in their own homes or on other premises not under the control of the person giving out the articles; (5) members of the employer's family dwelling in his house.

An injury, to give rise to a claim under the Acts, must be 'personal injury by accident.' The word 'accident' is to be taken in its popular and ordinary sense, as denoting an unlooked-for mishap or untoward event which is not expected or designed. Certain industrial diseases—specified in Schedule III. of the Act of 1906 and in Orders subsequently issued by the Secretary for State—are, for the purposes of compensation, deemed personal injury by accident. The accident must arise out of the workman's employment and also in the course of that employment. Both these conditions must be fulfilled. It is now settled by decisions of the House of Lords that an accident only arises out of and in the course of the employment when a causal connection exists between the employment and the accident. Section 7 of the Act of 1923 provides that an accident resulting in the death or serious and permanent disablement of a workman shall be deemed to arise out of and in the course of his employment, notwithstanding that the workman was at the time when the accident happened acting in contravention of any statutory or other regulation applicable to his employment,

or of any orders given by or on behalf of his employer, or that he was acting without instructions from his employer, if such act was done by the workman for the purposes of, and in connection with, his employer's trade or business. Compensation is not payable when it is proved that the injury was attributable to the workman's 'serious and wilful misconduct'; but the employer cannot escape liability on this ground in cases where the injury to the workman results in death or in serious and permanent disablement.

Where death results from the injury the compensation is a lump sum payable to the dependants of the workman. 'Dependants' are such of the members of the workman's family (wife or husband, parent or grandparent, step-father, step-mother, son, daughter, grandchild, step-son, step-daughter, brother, sister, half-brother, half-sister) as were wholly or in part dependent upon the earnings of the workman at the time of his death or would, but for the incapacity due to the accident, have been so dependent. Where the workman, being the parent or grandparent of an illegitimate child, leaves such child so dependent on his earnings or, being an illegitimate child, leaves a parent or grandparent so dependent upon his earnings, the word 'dependant' includes such illegitimate child and such parent or grandparent respectively. If the deceased workman leaves dependants who were wholly dependent upon him, the lump sum payable is an amount equalling 156 times his average weekly wages; but in no case more than £300 or less than £200. If he leaves dependants who were partially dependent the compensation is assessed according to the extent to which they were dependent upon him. Where the injury does not result in death, but in total or partial incapacity for work, the compensation is a weekly payment during the incapacity. The maximum weekly payment in case of disablement was, by the Act of 1923, increased to thirty shillings. In cases of total incapacity the weekly payment is an amount not exceeding 50 per cent. of the workman's average weekly earnings; but if that amount is less than twenty-five shillings a week the workman is entitled to a weekly addition, on a scale prescribed by the Act, which is treated as if it were part of the weekly payment. In cases of partial incapacity the Act of 1923 abolished the former discretionary power of the arbitrator to award such part of the difference between pre-accident and post-accident earnings as he might think proper, and has reduced the assessment of compensation to an arithmetical calculation. The main factors on which this calculation is based are the amount of the average weekly earnings of the workman before the accident and the average weekly amount which he is earning or is able to earn in some suitable employment or business after the accident. In ascertaining the compensation regard must be had to any payment, allowance, or benefit which the workman may receive from his employer during the period of his incapacity. Any weekly payment can be reviewed at the request either of the employer or workman, and, on such review, may, where a change of circumstances has occurred, be ended, diminished, or, subject to the maximum, increased.

Notice of the accident must—except in certain circumstances when the giving of notice is excused—be given to the employer as soon as practicable after the accident has happened and before the workman voluntarily leaves the employment in which he was injured. Under the Act of 1923 the notice may be given either in writing or orally. The notice must contain the name and address of the injured person, the cause of the injury, and the date of the accident. A claim for compensation has to be made within six months from the occur-

rence of the accident, or, in case of death, within six months from the time of death. The claim need not be made in any formal manner, but must be made in some definite form. A mere notice of accident is not a claim. A workman who has given notice of an accident must, if so required by the employer, submit himself for examination by a duly qualified medical man provided and paid for by the employer. So also where a workman is in receipt of a weekly payment the employer is entitled to require him from time to time to submit himself for medical examination. Where a weekly payment has been continued for not less than six months it may, on application by the employer, be redeemed by payment of a lump sum. The Act of 1923, sect. 24 (7), contains special provisions applicable to the case where the injured workman is under twenty-one years of age at the date when the application for redemption is made.

Any question arising as to liability to pay compensation or as to the amount or duration of compensation may be settled either by agreement or by arbitration under the Acts. An agreement may be made orally or in writing, or may be implied from the actions of the parties. A memorandum of the agreement should be sent to the registrar of the county court, or, in Scotland, to the sheriff clerk, who on being satisfied as to its genuineness must record it, whereupon it is for all purposes enforceable as a county court judgment or, in Scotland, as a sheriff court decree. In England arbitrations under the Acts usually take place before the county court judge or some person appointed by him. Under the Act of 1923, sect. 11 (3), the judge may in any case, if he thinks fit, and must, if either party so requires and gives security for the prescribed fee, summon a medical referee to sit with him as assessor. An appeal lies to the Court of Appeal and thence to the House of Lords from the decision of a county court judge on any question of law. In Scotland an appeal lies from the arbitrator—the sheriff—by stated case on a question of law to the Court of Session and thence to the House of Lords.

Where the injury is so caused as to give the workman a right to damages against the employer at common law or under the Employers' Liability Act, 1880, he may, at his option, either claim compensation under the Workmen's Compensation Acts or bring an action for damages. The workman is put to his election to take the one course or the other. Under the Act of 1923, sect. 18, however, the workman, provided he brings the action for damages within six months from the occurrence of the accident causing the injury, is entitled, if it be held in such action that the injury is one for which the employer is not liable in damages, to ask the court which determines that action to award him compensation under the Workmen's Compensation Acts, subject to the deduction of costs caused by his bringing the action for damages instead of taking arbitration proceedings. Where the injury is so caused as to give the workman a right to damages against a third person, he can both bring an action for damages against that third person and claim compensation from the employer, but he cannot recover damages from the third party and also compensation from his employer in respect of the same injury.

Disputes arising out of contracts of service have long been the subject of statutory regulation. For many centuries the justices of the peace exercised, under various statutes, important functions in the determination of such disputes. The Conspiracy and Protection of Property Act, 1875 (38 and 39 Vict. chap. 86), repealed the Master and Servant Act, 1867, and other statutes under which the justices were empowered to inflict fine and imprisonment in

case of breach of contract or other misconduct. That statute makes the wilful and malicious breach of a contract of service an offence punishable with fine or imprisonment in only two cases: (1) where the person in breach knows or has reasonable cause to believe that the probable consequences of his breach of contract will be to endanger human life or cause serious bodily injury, or to expose valuable property to destruction or serious injury; and (2) where the person in breach is employed in the supply of gas or water. (For the law as to combinations of workmen or of masters, see COMBINATION, CONSPIRACY, TRADE UNIONS.) In disputes between an employer and a workman a county court, or, in Scotland, the sheriff court, possesses, under the Employers and Workmen Act, 1875 (38 and 39 Vict. chap. 90), a special statutory jurisdiction to adjust and set off the one against the other all claims on the part either of the employer or of the workman arising out of the employment, and, in cases of breach of contract, to take security for the performance of the contract in lieu of awarding damages. The powers thus conferred by the Act on a county court may, in cases where the amount claimed does not exceed £10, be exercised by a court of summary jurisdiction—the justices, in relation to any such dispute, being deemed to be a court of civil jurisdiction. The expression ‘workman,’ as defined in this Act, does not include a domestic or menial servant but, subject to that exclusion, extends to ‘any person who, being a labourer, servant in husbandry, journeyman, artificer, handicraftsman, miner, or otherwise engaged in manual labour,’ has entered into or works under a contract with an employer, whether the contract be a contract of service or a contract personally to execute any work or labour. The Conciliation Act, 1896 (59 and 60 Vict. chap. 30), was passed with the view of preventing disputes through the establishment of conciliation boards representing both employers and workmen. Provision is made under this Act and a subsequent Act passed in 1916 for the registration of such boards at the Ministry of Labour, and for the intervention of the Ministry of Labour itself in order to bring about the amicable settlement of trade disputes. The Industrial Courts Act, 1919, established a permanent industrial court, consisting of persons appointed by the Minister of Labour, to which trade disputes may be referred for settlement, and also made provision for the setting up of courts of inquiry into the causes and circumstances of any actual or apprehended trade dispute. The Act does not bring into operation any principle of compulsory arbitration, as the consent of both parties to an industrial dispute must precede any reference to the industrial court. But such consent is not required for the purpose of setting up a court of inquiry into the causes and circumstances of a dispute.

In recent years parliament has intervened to secure payment of minimum rates of wages in certain industrial employments. Under the Coal Mines (Minimum Wage) Act, 1912, it is an implied term of every contract for the employment of a workman underground in a coal mine that the employer shall pay to that workman wages at not less than the minimum rate settled by the joint district boards appointed for that purpose in the various districts concerned and applicable to that workman. The district boards are also entrusted with the duty of making district rules regarding the exclusion from the right to wages at the minimum rate of aged and infirm workmen and of workmen who fail to comply with conditions as to regularity and efficiency of work. Again, under the Trade Boards Acts, 1909 and 1918, trade boards, on which both employers and

workers are represented, have been established for the purpose of fixing minimum rates of wages for both time-work and piece-work in certain trades. Trade boards were first instituted in 1909 pursuant to the Act of that year, which was passed as a result of the inquiries into the conditions existing in a number of industries. In 1916 the Ministry of Labour was made the central authority. Trade boards are established not only in the trades specified in the Acts but also in other trades to which the Acts have been applied from time to time, as provided in the Act of 1918, by special order of the Minister of Labour on his being satisfied that no adequate machinery exists for regulating wages throughout the trade. After rates have been fixed by a trade board and made obligatory by order of the Ministry of Labour an employer is punishable for employing any persons at wages lower than the rates so fixed. The rates fixed by a trade board may be fixed so as to apply universally to the trade, or so as to apply to any special process in the work of the trade, or to any special class of workers in the trade, or to any special area. (As to statutory provisions regulating working conditions, see FACTORY AND WORKSHOPS ACTS, MINING.) The statutory regulations with respect to contracts of sea service are contained in the Merchant Shipping Acts.

In Scotland the relation of master and servant is constituted by a contract, *locatio conductio operarum*, in which the one party hires the services of the other in a particular capacity. A contract *locatio conductio operis*, in which a person undertakes for a consideration to do a particular job or perform a specific service for another, does not subject the person undertaking the work to the order and control of the other as to the manner in which he shall do his work and does not create the relation of master and servant. The rules of Scots law regulating the control of service are, generally speaking, substantially similar to those of English law, and the modern statutes affecting the incidents of such a contract apply to both countries. A contract of service for not more than a year may be constituted by verbal agreement and proved by parole evidence. A contract of service for more than a year is not binding unless it is constituted by a writing probative of both parties. If the period of service is not expressed in the contract, certain presumptions, applicable to ordinary classes of service, arise in regard to the duration of the engagement. Thus domestic servants are presumed to be hired by the half-year, beginning at Martinmas or Whitsunday, and farm servants and gamekeepers by the year; but these presumptions yield to proof of a contrary intention, regard being had to the circumstances of the case and the custom of the district in respect of the particular kind of service. Under the Removal Terms (Scotland) Act, 1886 (53 and 54 Vict. chap. 36), where a servant is hired by the year or half-year commencing or expiring at one or other of the terms of Whitsunday or Martinmas, he, in the absence of express stipulation to the contrary, is bound to enter upon or quit the service on 28th May or 28th November at noon, or on the following day at noon when the term falls on a Sunday. In the case of those classes of servants—agricultural, domestic, and the like—who are customarily hired by the year or half-year, the engagement, if at the expiry of the period no other arrangement is made by the parties, is held to be renewed by tacit relocation for another period of the same duration. In order to prevent the operation of tacit relocation it is necessary that notice or warning be given by the master to the servant or by the servant to the master forty days before the term. The notice or warning may be express or may be implied from words or acts

plainly indicating that the contract is to come to an end. In the case of other servants, where there exists no stipulation or custom in the employment as to the length of notice, reasonable notice must be given. The wages of labourers, farm servants, manufacturers, artificers, and work-people were, by statute (33 and 34 Vict. chap. 63), declared free from any arrestment unless in so far as they exceed twenty shillings a week, or unless the arrestment is in virtue of a decree for aliment or for rates and taxes, and sets forth the nature of the debt; and by the Small Debt (Scotland) Act, 1924 (14 and 15 Geo. 5, chap. 16, sect. 2), the limit was raised to thirty-five shillings a week. Servants' wages fall within the triennial prescription (see DEBT) unless in cases where the debt or action for wages is founded on a written obligation. The prescription applies to the wages of any kind of servant. The three years are reckoned from the date when the wages fell due, each term's wages running a separate prescription. The effect of the triennial prescription is not to extinguish the debt but to alter the *onus* of proof and limit the mode of proof. When the prescription has run the creditor must prove not only that the debt was incurred but that, three years afterwards, it was still resting owing, and he is limited to proof by the writing or the oath of the debtor.

The system of National Health Insurance and Unemployment Insurance, established by recent statutes, is dealt with *sub voce* INSURANCE.

On English Law of Master and Servant, see C. Manley Smith (London, 7th ed. 1922); J. Macdonell (2d ed. 1908); on Scots Law of Master and Servant, Fraser (3d ed. 1882); Umpherston (1904); on Workmen's Compensation Acts, W. A. Willis (23d ed. 1925); Elliott (8th ed. 1925, by Berryman); on Employers' Liability to their Servants, Dawbarn (4th ed. 1911); Slessor and Henderson, *Industrial Law* (ed. 1924).

Master of Arts (abbreviated M.A., and sometimes, particularly in America, A.M.) is a degree conferred by universities and some colleges. In the universities of England this title follows that of Bachelor (q.v.). The dignity of Master (*Magister artium liberalium*) was held in high esteem in the middle ages. In Germany it is now obsolete, having been superseded by that of doctor. A Master has the right to vote in congregation or convocation at Oxford, and in the senate at Cambridge, and consequently enjoys the university franchise; in the Scottish universities Masters (there are no Bachelors of Arts) are members of the General Council, and as such elect the parliamentary representatives for the university. See DEGREES.

Master of Ceremonies, of the Rolls, &c. See CEREMONIES, ROLLS, &c.

Masters, EDGAR LEE, American author, was born at Garnett, Kansas, in 1869, and admitted to the bar in 1891. In 1893 he published *A Book of Verses*. 1905 saw the issue of *Blood of the Prophets*, and 1907 and 1908 two plays, *Althea* and *The Trifler*. *Spoon River Anthology* (1915), by which he is chiefly known, is a collection of clever satirical verse epitaphs on (and professedly by) the 'dear departed' of a small middle western town. Later work, as *Starved Rock* (1919), *Domesday Book* (1921), and *Children of the Market Place* (1923), has not gained the same popular appreciation.

Masterwort (*Peucedanum Ostruthium*), a perennial herb of the natural order Umbelliferae. It is a native of Europe, and is found in moist pastures in some parts of Britain, but apparently naturalised rather than indigenous, its root having formerly been much cultivated as a pot-herb, and held in great repute as a stomachic, sudorific,

diuretic, &c. The root has a pungent taste, causes a flow of saliva and a sensation of warmth in the mouth, and often affords relief in toothache. *Astrantia major*, a herb belonging to the same natural order and having similar properties, is also named Masterwort.

Mastic, a species of gum-resin yielded by the Mastic or Lentisk tree (*Pistacia Lentiscus*, natural order Anacardiaceae). It oozes from cuts made in the bark, and hardens on the stem in small round tear-like lumps of a light straw colour, or, if not collected in time, it falls on the ground, where it acquires some impurities. Its chief use is in making the almost colourless varnish for prints, maps, drawings, &c. It is also used by dentists for stopping hollow teeth, and was formerly employed in medicine. The chief source is the island of Chios, where a particular variety of the tree has been cultivated for about 1000 years.—The name of mastic is also given to oleaginous cements, composed of about 7 parts of litharge and 93 of burned clay, reduced to fine powder, made into a paste with linseed-oil.

Mastiff. The characteristics of the mastiff group of dogs are very marked and constant. One variety of the breed has been known from ancient times as the English, another as the Bordeaux or mastiff of Gaul. These may be classed as the European, while another kind is the Asiatic, of which the Tibetan is perhaps the most typical. No group of domestic dogs has more appearance of being an original and distinct species, although the English mastiff has been crossed and recrossed from time to time, principally with the object of increasing the size; and, while the blood of the Asiatic variety was very probably introduced at an early date, subsequently crosses with the Alpine mastiff, the St Bernard, the boarhound, and the bulldog have undoubtedly been introduced, and the modern English mastiff must be regarded as a composite breed.

The English mastiff is thick-set and powerful, with a large head and broad, short, truncated muzzle, large, thick, pendulous lips, ears formerly often semi-erect, now hanging and of moderate size, smooth-coated, with frequently a full but not bushy tail. This variety formerly averaged from 25 to 28 inches at the shoulder, but since the middle of the 19th century, owing to repeated crossing and selection, an average of from 30 to 32 inches has been obtained, perhaps somewhat to the loss of muscular power and activity. The colours are all shades of fawn, tan, and black, with and without mixture of white. Formerly red and brindle were the commonest colours, but owing to selection fawn in all shades is now the most prevalent, with the muzzle, ears, and other extremities shaded with darker (often black) markings.

The mastiff was formerly very courageous, and would readily attack the lion or bear; now it is chiefly valued for exhibition purposes. As a companion or watch-dog no other variety equals it, for, while faithfully protecting the property entrusted to it (at times with marvellous sagacity and discrimination), it has the additional merit of generally refraining from the infliction of personal injury on the invader. It becomes ardently attached to its master, although not demonstratively affectionate. It has an excellent nose, but is of little or no use for sporting purposes, and dull at learning any kind of tricks.

The mastiff of Tibet was larger than the old English, but is smaller than the modern English mastiff, averaging from 27 to 30 inches at shoulder. The head is longer, narrower, and more elevated at the back or cone, the skin much looser, and forming a fold from the eyebrows which descends

to the lips, these being more pendulous than in the English variety, and partaking more of the character of the bloodhound. The hair is rough and dense, the tail bushy and curled generally over the back, colour mostly black, with tan or fawn shadings over the eyes, on the paws, and under the belly; but fawn-coloured specimens are not uncommon. Dogs of this kind are found in Nepal, Bhutan, Tibet, Mongolia, and probably northward through Russia and Siberia, in a state of more or less purity; and dogs presenting the characteristics of the Asiatic mastiff and of vast size appear to have existed since the days of the Assyrian empire, 650 B.C. See the Rev. M. B. Wynn's *History of the Mastiff* (1886).

Mastodon, a genus of extinct elephants, whose remains are found in Europe, Asia, and America, in Miocene, Pliocene, and Pleistocene strata. They equalled or excelled their modern relatives in size. The name mastodon refers to the mammillary cusps or teat-like prominences on the molar teeth. See ELEPHANT.

Masûdi, ABUL HASSAN ALI, an Arab traveller and author (died 957), was born at Bagdad about the end of the 9th century, and spent great part of his life in travel, visiting Egypt, Palestine, the Caspian shores, India, Ceylon, Madagascar, and perhaps even China. His chief works are the *Annals*; *The Meadows of Gold*, printed with a French translation by Meynard in 1861-77 (one vol. of an English translation by Sprenger in 1841); and the *Indicator* (1894).

Masulipatam, the principal seaport of Kistna district in the Presidency of Madras, lies 215 miles N. of Madras City. Vessels anchor 5 miles from shore. Here the English established an agency in 1611, and after 1628 it became the centre of their trade in those parts. Since 1841 the town has been an active missionary centre. In 1864 a storm-wave destroyed 30,000 lives. Pop. (1881) 35,056; (1921) 43,940, many of whom weave cottons.

Masuri, or MUSSOORIE, a hill-station and sanatorium in Dehra Dûn district, United Provinces, and practically one town with Landaur (q.v.). It contains numerous schools for the education of European and Anglo-Indian children. Pop. 8000, more than doubled in the hot season.

Masurians, MASOVIANS, or MAZOVIANs, a Polish (or closely kindred) people inhabiting the south of East Prussia ('Masurenland') and the adjacent parts of Poland (q.v. for the mediæval duchy of Mazovia, which included Warsaw). In the East Prussian region the townsmen are German, and the whole so far germanised and Protestant as to vote almost unanimously for German nationality in 1921. There is a maze of great lakes (Spirdingsee, Löwentinsee, Mauersee, &c.). See TANNENBERG, WAR (GREAT). Polish Mazovia is Roman Catholic.

Masurium, an element of atomic number 43, whose discovery by Dr Nonnack and Frl. Tacke was announced in 1925.

Matabeleland, a country stretching northwards from the Limpopo River, which separates it from the Transvaal, and having Khama's territory on the south-west. It measures about 180 miles from north to south and 150 from east to west, and embraces the watershed between the Zambezi and Limpopo systems. The Matabele, the inhabitants of the country, are a warlike Zulu people of mixed stock, who, driven out of the Transvaal by the Boers in 1837, crossed the Limpopo under their chief Mosilikatze. After remaining for a while in what is now the Transvaal they finally settled in 1840 beyond the granitic Matoppo Mountains, subduing and almost exterminating the peoples they found there—the Mashona (see

MASHONALAND), and the closely allied Makalaka and Banyai, the first now occupying the mountain fastnesses in the northern part of the country, the second now dwelling south-east of the Makalaka, along the middle course of the Limpopo. In 1890 the country was handed over to the Imperial British South Africa Company, who, as the Matabele renewed their raids and forays in July and August 1893, organised an expedition in three columns supported by some regular British troops and by Khama and his Bamangwato, against King Lobengula, the son of Mosilikatze. The expedition, which advanced on 2d October, was completely successful against the savage warriors, who could not stand before the Maxim guns, and, after some sharp fighting, broke up their military organisation. Lobengula died in hiding in February 1894. Soon after the Jameson Raid into the Transvaal (at New Year 1896) the Matabele seized the opportunity of reasserting their independence; the native armed police mutined, and Bulawayo, the capital, was blockaded. The British South Africa Company, its officers, and settlers strained every nerve, and had practically pacified the country by the end of the year. The Matabele in place of warriors are now herdsmen and agriculturists. Quartz reefs rich in gold exist in various parts of the country. Matabeleland, with Mashonaland, now forms Southern Rhodesia. See RHODESIA.

Matadi, a river-port of Belgian Congo, on the left bank of the Congo, about 100 miles from its mouth, is the starting-point of the railway to Stanley Pool (250 miles).

Matanzas, a fortified town and seaport of north Cuba, 47 miles E. of Havana. It is a well-built town, situated in an exceedingly rich and fertile district; has a cathedral, a castle, an excellent harbour, a large trade in sugar, molasses, rum, and cigars; and contains several distilleries, iron-foundries, petroleum and other works. The celebrated white limestone caves of Belamar and the beautiful Yumuri valley are near. Pop. 45,000.

Matapan, CAPE, the southernmost point, bold and precipitous, of the Morea in Greece, 36° 22' N. lat.

Mataró, a seaport of Spain, 20 miles NE. of Barcelona, has cotton, sailcloth, glass, and machinery factories, iron-foundries, and shipbuilding-yards, besides a marine school; pop. 28,000.

Matches, the name now given to splints of wood tipped with some composition (often containing phosphorus) to produce a light by friction. These came into general use about the year 1834. Before that the common light producer was the flint and steel along with a tinder-box. The tinder (charred cotton) was set on fire by sparks from the flint and steel, but did not burst into flame. For more primitive methods see FIRE. Among other devices formerly employed were the burning-glass (see HEAT, LENSES, MIRROR); Döbereiner's lamp (see DÖBEREINER); the *oxymuriatic match*, a splint tipped with a mixture of chlorate of potash and sugar, which took fire on contact with sulphuric acid; and the *lucifer match*, which was tipped with a paste containing chlorate of potash and sulphide of antimony that ignited when drawn across sand-paper—it required to be rubbed with a good deal of pressure, and as it gave off sparks it was not free from danger. The introduction of phosphorus in 1834 was a great improvement, and of red phosphorus a greater.

The chief operations in the manufacture of matches embrace (1) cutting the wood splints, (2) immersing the splints in melted paraffin, and (3) preparing the igniting composition and dipping the splints into it. There is also the making of the boxes, which, in the case of safety-matches, have the phosphorus composition glued

upon their sides. Pine or aspen is the wood used for the splints.

There are several kinds of splint-cutting machines. One of the simplest is a special kind of lathe for which the tree trunks to be operated upon are sawn across in pieces 14 inches long, and the bark removed. One of these pieces is the length of seven matches, and is fixed on the chuck of the lathe and cut into a continuous slice or shaving equal to a match in thickness. The principal cutting tool is fixed on the slide-rest, and as the shaving comes away it is divided into seven equal widths by cutters placed above the chief slicing tool. After the two-inch-wide shavings are cut into six-foot lengths, they are divided into single splints by a guillotine cutter similar to that used for cutting paper. In favourable circumstances this machine will cut a million splints an hour.

A filling-machine supplies the splints to the dipping frame, in which they are held in rows between laths. The igniting composition is spread of the proper thickness on a heated iron table, and the splints dipped into it to form them into matches. The rooms where the igniting-mixture is prepared and the matches dipped are, or at least were, the most unhealthy parts of a match-factory. In former days especially, among those who worked in these rooms, cases of necrosis or caries of the lower jaw ('phossy jaw') occurred from the action of the phosphorus fumes; now, however, by the lessened quantity of phosphorus used in the dipping-mixtures and by improved ventilation this disease has diminished; it never occurs at all where red or amorphous phosphorus (see PHOSPHORUS) is employed. In 1906, at an international conference in Bern, seven states, joined later by the United Kingdom, signed a convention prohibiting the use or sale of matches in which white (or yellow) phosphorus was used. The extension of this convention was referred to the first International Labour Conference (at Washington, 1919) under the League of Nations.

The paste used for the dipping of matches consists of a combustible material as red phosphorus, phosphorus sulphide; an oxidising agent or agents as chlorate of potash, nitrate of potash (which gives a more noiseless match than the chlorate), oxide of manganese, the red oxide or the dioxide of lead; a binding material as glue, gum, dextrine; a material to increase friction or retard chemical action as powdered glass, sand, whiting; a colouring matter as vermilion, ultramarine, umber, aniline dye; and, of course, some water (slightly heated) is also used. Nearly every manufacturer has his own special mixture. For one kind of *safety* or 'Swedish' match, a match, that is, which can only be struck on a specially prepared surface, the dipping composition consists of chlorate of potash, of sulphide of antimony, and of glue; and the rubbing-surface of a mixture of amorphous phosphorus, of sulphide of antimony, and of glue.

Vestas only differ from ordinary matches in the stalks being formed of bits of stearin tapers (called wax-tapers) instead of wood splints. *Vesuvians* used by smokers consist of a hard wood, or sometimes a hollow glass stalk, with a bulbous head formed of some slow-burning compound, such as a mixture of charcoal, saltpetre, sand, and gum, tipped with the igniting composition of ordinary matches. *Flamers*, also for the use of smokers, have a thick head of a flaming mixture, with either a 'wax-taper' or wood stalk. See W. H. Dixon, *The Match Industry* (1925).

Matchlock. See FIREARMS.

Mate is an assistant, a deputy, or a second in any work. In the navy the use of the term is now confined to petty officers, such as boatswain's-mate,

gunner's-mate, &c. In the merchant-service the mates are important officers, holding functions not greatly inferior to those of lieutenants in the royal navy. The first mate ranks next to the master or captain, commands in his absence, and is immediately responsible for the state of the vessel; the second and third (and fourth in large vessels) have various analogous duties.

Maté, or PARAGUAY TEA, a drink extensively used in South America, and almost universally through Brazil. It consists of the leaves and green shoots of certain species of Holly (q.v.),

Maté (*Ilex paraguayensis*).

more especially *Ilex paraguayensis*, dried and roughly ground; the leafy portion being reduced to a coarse powder, and the twigs being in a more or less broken state. Some species of *Symplocos* (family *Symplocaceæ*), especially *S. lanceolata* and *S. Itatiaia*, of southern and central Brazil, are also reported to be used. The term *maté*, which has by usage attached to this material, belonged originally to the vessels in which it was infused for drinking; these were usually made of gourds or calabashes, often trained into curious forms during their growth. Into the hollow vessels thus formed a small quantity of the material, more properly called *Yerba de Maté*, is put, and boiling water is added; it is then handed round to those who are to partake of it, and each, being provided with a small tube about eight inches in length, with a small bulb at one end, made either of basket-work of wonderful fineness or of perforated metal, to act as a strainer and prevent the fine particles from being drawn up into the mouth, dips in this instrument, which is called a *bombilla*, and sucks up a small portion of the infusion, and passes the *maté*-bowl on to the next person. It is usual to drink it exceedingly hot, so much so as to be extremely unpleasant to Europeans. Its effect is much the same as tea, stimulating and restorative; and it derives this property from the presence of a large proportion of the same principle which is found in tea and coffee—viz. *Theine*. The collection and preparation of *maté* is a large industrial occupation in Paraguay and Brazil.

Matera, a city of the Italian province Potenza, situated 37 miles NW. of Taranto. Pop. 18,000. Here is the cathedral of the archbishopric of Acerenza and Matera. There are numerous caverns and stone-quarries in the vicinity.

Materialism is the theory of the world which professes to find in matter (monistic or philosophical materialism), or in material entities (atomistic materialism), or in material qualities and forces (scientific or physical materialism), a complete explanation of all life and existence.

whatsoever. Early philosophies are generally either theogonies or cosmogonies. Cosmogonies tend to postulate animated or living matter (hylozoism). Out of the earliest hylozoistic philosophemes of the Ionic school in Greece arose the atomistic materialism of Leucippus and Democritus, explaining the cosmos as an aggregation and segregation of ultimate indivisible material entities or atoms. The atomic theory of Democritus became the basis of the sensationalistic psychology and ethic of Epicurus, and was transmitted in the glowing verses of Lucretius' great didactic poem, *De Rerum Natura*, on to the later Roman period. Materialism as a basis for scientific research we find revived in history wherever a movement arose in favour of the methods and aims of experimental or natural science, as in the Renaissance period in Europe generally. Gassendi, though, it is who must be regarded as the renewer *par excellence*, in modern times, of systematic materialism. He developed the doctrine of Democritus, by endowing the atoms with force and even with sensation. Lamettrie, by his materialistic account of the functions of the mind, prepared the way in France for the comprehensive materialism of Baron Holbach, whose *Système de la Nature* is the *chef-d'œuvre* of French materialism. In Holbach materialism reaches its high-water mark. Applying materialism to anthropology, he seeks to show that man is only a physical being, and that morality or virtue is independent of the supports of positive religion and of theism.

The empirical method of Bacon and Locke, taken along with some things Locke said about matter being possibly made to think, and eagerly caught up by men like Voltaire, had countenanced in England as well as in France a materialistic treatment of the mental and spiritual powers of man, as in the works of Hobbes, Hartley, and Priestley. In Germany philosophy was in the main idealistic and speculative until the death of Hegel, but Vogt about 1850 applied the principles of materialism to psychology, holding that physiology pronounced definitely and categorically against the idea of individual immortality, as indeed against all notions founded on the idea of the independent existence of the soul. Moleschott and Büchner are associated with Vogt as upholders of materialism. Büchner's *Kraft und Stoff* ('Force and Matter') is the Bible of German materialism. Feuerbach and Strauss may be mentioned as philosophers who exchanged the spiritualistic monism of Hegel for materialistic monism.

The form in which materialism now appears has been determined by the doctrine of evolution. Materialism indeed might be said to have been absorbed in the wider theory of evolution, which goes beyond the mere antitheism or atheism of materialism, and seeks *positively* to show how the diversities and differences in the world can be accounted for by natural as opposed to supernatural or creative process. Haeckel became perhaps the most prominent upholder of a materialism based on evolution.

Materialism may be examined from many points of view. (1) Materialism is scientific realism. It believes, i.e., in real physical entities, such as atoms and forces, and spaces and times. Now a belief in atoms leads, in physics, in chemistry, and in astronomy, to insoluble contradictions: atoms, for example, for physical purposes must be at once absolutely impenetrable and unalterable, and yet absolutely elastic and alterable. It would be more correct, in fact, to reduce matter to forces than to atoms, as many theorists have done. But it is difficult to think of forces existing without some sort of substrate. Spaces and times, too, are not physical things. Thus science is full of hypotheses; nor can it dispense with hypotheses. Complete physical realism or materialism is, in short, theo-

retically impossible. (2) Even granting—which in strictness we cannot—the existence of 'mere matter,' science has as yet found insuperable difficulty in passing from unorganised to organised matter. (3) Psychology has as yet been unable to regard organic states as accounting for psychological or mental states. The two are totally different, and, though correlated, cannot be said to be causally connected. (4) Materialism cannot furnish a complete or consistent ethical theory. If man is entirely the product of natural forces, and in fact the sport of natural forces, it is meaningless to think or speak of him as morally obliged either to follow or to resist nature. Man not only follows and resists nature, but in mechanical and artistic construction commands and anticipates and surpasses nature. Of course to materialism the belief in human freedom, which practically makes history, is an illusion, but it is difficult to see how on the materialistic hypothesis even this illusory belief could have arisen. (5) Although materialistic evolution may succeed in showing that we ought not to regard certain natural adaptations and productions as special and final creations, it cannot and does not avoid the question of teleology. Neither hylozoism nor mechanism, nor unconscious selection and adaptation accounts for that relativity of everything to everything, which is really what at bottom is meant by teleology. There must be a world-soul or world-thought for whom the universe is realised end. (6) There is the philosophical question about mere matter. It has again and again been confessed by scientists as well as by philosophers that by matter can only, in the last resort, be meant what J. S. Mill calls the permanent possibility of sensation. There is in fact no object (or objective thing) without a subject (or consciousness). If the materialist at once reply that there is no subject without an object, he is in the right as against the thesis. The idealist, in short, and the materialist are in the right as against each other. Subject and object imply each other. We cannot begin with either in order to explain from it the other.

Materialism brings prominently before us that side of the universe which is compassed by the methods of physical science. But physical science, like (say) economic or theological or mental science, takes a one-sided or 'abstract' view of experience. All sciences 'abstract' from the concrete whole of experience certain facts which they propose to investigate in detail. Physicists, like metaphysicians and theologians, are apt to become dogmatical about spheres of inquiry of which they know professedly nothing.

BIBLIOGRAPHY.—Text-books of Materialism which have not already been mentioned are: Gassendi, *De Vita, Moribus, et Doctrinis Epicuri* (Leyden, 1647); Lamettrie, *L'Homme Machine* (Leyden, 1748); Haeckel, *Natürliche Schöpfungsgeschichte* (1868; Eng. trans. 2d ed. 1875-76); *Die Welträtsel* (1899; Eng. trans. new ed. 1913); Wiener, *Grundzüge der Weltordnung* (1863-69); and Huxley's Address at Belfast, 1875. For an examination of Materialism, see any account of Kant's *Critical Philosophy*, or the statement of Dogmatism given in *Fichte*, by Adamson; also *As regards Protoplasm*, by Dr Hutchison Stirling; *Concepts of Modern Physics*, by J. B. Stalls, containing a sifting examination of the atomic theory; *Reign of Law*, by the Duke of Argyll; and St George Mivart's books. The best history of Materialism is Lange's *Geschichte des Materialismus* (trans. 1881; new ed. 1925).

Materia Medica is that department of the science of medicine, belonging partly to pharmacology, partly to therapeutics, which treats of the materials employed for the alleviation and cure of disease, their properties, physiological actions, and uses. See PHARMACOPŒIA, POISONS, MEDICINE, APERIENTS, and articles on the various drugs.

Mathematics (Gr. *mathēma*, 'learning'), the science which has for its subject-matter the properties of magnitude and number. It is usually divided into *pure* and *mixed* or *applied*; the first including all deductions from the abstract, self-evident relations of magnitude and number, the second the results arrived at by applying the principles so established to certain relations found by observation to exist among the phenomena of nature. The branches of pure mathematics which were first developed were, naturally, *Arithmetic*, or the science of number, and *Geometry*, or the science of quantity (in extension). The latter of these was the only branch of mathematics cultivated by the Greeks, their cumbrous notation opposing a barrier to any effective progress in the former science. Algebra or the science of numbers in its most general form is of much later growth, and was at first merely a kind of universal arithmetic, general symbols taking the place of numbers; but its extraordinary development within the last two centuries has established for it a right to be considered as a distinct science, the *science of operations*. Combinations of these three have given rise to trigonometry and analytical geometry. All those sciences in which a few simple axioms are mathematically shown to be sufficient for the deduction of the most important natural phenomena are regarded as belonging to applied mathematics. This definition includes those sciences which treat of pressure, motion, light, heat, sound, electricity, and magnetism—usually called *Physics*—and excludes chemistry, geology, political economy, and the other branches of science, which, however, receive more or less aid from mathematics. See *GEOMETRY*, and the works there cited; as also, besides articles on the subjects named above, and many others, the following:

Mather, INCREASE, a famous American colonial divine, was the sixth son of Richard Mather, an English Nonconformist minister, who emigrated to Massachusetts in 1635. He was born at Dorchester, Massachusetts, June 21, 1639, graduated at Harvard College in 1656, and again at Trinity College, Dublin, in 1658. His first charge, at Great Torrington in Devonshire, was given him on the advice of John Howe. He next preached in Guernsey, but in 1661, finding it impossible to conform, returned to America, and in 1664 was ordained as pastor of the North Church, Boston, where he remained till his death, August 23, 1723. In 1681 he was also chosen president of Harvard College. An industrious student, he published no less than 136 separate works, most of which are now very scarce. Of these the most interesting, *Remarkable Providences* (1684), was reprinted in London in 1856. The *History of the War with the Indians* (1676) was reprinted at Boston in 1862. Mather's influence was great in the colony, and in 1689 he was sent to England to lay its grievances before the king. He was successful in obtaining a new charter from William III., and on his return was thanked by the speaker of the general assembly. The same year he became the first D.D. of Harvard. To his credit he was far less an alarmist about witchcraft than his son, and he had the good fortune to be absent in England during the time of fiercest excitement in the Salem mania. His *Causes of Conscience concerning Witchcraft* (1693) did much to cool the heated imaginations of the New England colonists, and saved lives by refuting the doctrine of 'spectral evidence.'

His son, COTTON MATHER, was born in Boston,

February 12, 1663, and graduated in 1678 at Harvard, where his precocious learning and piety excited great expectations. He entered upon a course of fasting and vigils, cured a habit of stammering by speaking with 'dilated deliberation,' studied theology, and became the colleague of his father in the ministry of the North Church at Boston. His industry was phenomenal and his learning remarkable, while his vanity and fluency enabled him to pour from the press as many as 382 books. He took a fatal interest in witchcraft, and his *Memorable Providences relating to Witchcraft and Possessions* (1685) did much to fan the cruel fury of the New Englanders. The first phenomena of the notorious Salem witchcraft mania occurred in 1692, and Mather plunged into the discussion, and to convince the world wrote his *Wonders of the Invisible World* (1692). While it is true that his contemporaries fully shared his belief in witchcraft, none pursued the inquiry with such hateful zeal, and on the head of none rests a heavier burden of bloodguiltiness. Even himself afterwards confessed that 'there had been a going too far in that affair.' Mather died February 13, 1728.

Cotton Mather's chief work is *Magnalia Christi Americana* (1702), an undigested mass of materials for the church history of New England. His feeble *Essays to do Good* (1710) was much esteemed by Franklin. His life was written by his son, Samuel Mather (1729). See also Charles W. Upham, *History of the Salem Delusion, 1692* (1831); Enoch Pond, *The Mather Family* (1844); and Wendell, *Cotton Mather* (1891).

Mathew, THEOBALD, commonly known as FATHER MATHEW, an eminent Irish apostle of temperance, was born at Thomastown in Tipperary, 10th October 1790. He studied for the Roman Catholic priesthood at Kilkenny and for a short time at Maynooth, but instead of becoming a secular priest entered the religious order of the Capuchins, in which he took priest's orders in 1814, and was sent to the church of his order in the city of Cork. Here he devoted himself to the ceaseless labours of his calling with untiring zeal, and, finding that the poverty and degradation of his people were to a great extent directly due to over-drinking, was driven by his enthusiastic temper to advocate the drastic remedy of total abstinence. In 1838 he began his crusade, which quickly grew beyond the bounds of Cork, and extended to Dublin, to the North, to Liverpool, Manchester, London, Glasgow, and the other chief seats of the Irish population, even in the New World itself. His success had something of the marvellous in its character. The form of engagement partook of the religious, and was accompanied by the presentation of a medal, to which the utmost reverence was attached by the recipient. The enthusiasm declined amid the sufferings of the potato-famine, and Father Mathew died, worn out by his labours, 8th December 1856. See Harriet Martineau's *Biographical Sketches*, and Lives by J. F. Maguire (1863), F. J. Matthew (1890), and Katherine Tynan (1908).

Mathews, CHARLES, comedian, was born in London, 28th June 1776, and educated at Merchant Taylors'. His father was a bookseller, and intended his son to follow the same 'serious calling'; but his early inclination for the stage overcame parental counsel, and he made his first appearance as an amateur—in the part of Richmond—at the Richmond theatre in 1793, and as a professional comedian in the Theatre Royal, Dublin, the following year. He then served an apprenticeship in the famous York company under Tate Wilkinson, and made his first appearance in London on 15th May 1803 at the Haymarket, then managed by George Colman. Next year he played at Drury Lane, and he afterwards acted at Covent Garden and the

Lyceum; but he was not satisfied with the class of part given to him, and in 1818 he took up the profession of 'entertainer' and made an immense success with his 'At Home' and other entertainments. In this he passed the remainder of his life, appearing frequently in the provinces and visiting America twice. He died at Plymouth on 28th June 1835. Mathews was a true comedian, with extraordinary powers of impersonation, entering into the very mind of the persons he imitated. He was not merely a 'mimic'—one who reproduces oddities and peculiarities: he *was* the person he represented. See his *Memoirs* by Mrs Mathews (4 vols. 1838-39).—His son, CHARLES JAMES (born 26th December 1803; died 24th June 1878), was a delightful light comedian, with no depth of feeling, but with charming grace and delicacy. In 1838 he married the famous Madame Vestris. See his *Life, chiefly Autobiographical*, edited by Charles Dickens (2 vols. 1879).

Mathias Corvinus. See MATTHIAS.

Mathurá. See MUTTRA.

Matico (*Piper angustifolium*), a shrub of the Piperaceæ, a native of Peru, remarkable for the styptic property of its leaves which are used for stanching wounds, and for other medicinal qualities.

Matilda (1102-67), 'the Empress Maud,' was the only daughter of Henry I. (q.v.) of England. She was married in 1114 to the Emperor Henry V., and after his death in 1128 to Geoffrey of Anjou, by whom she became mother of Henry, afterwards Henry II. (q.v.) of England. There was civil war between her and Stephen (q.v.) from 1139 to 1147.

Matilda, Countess of Tuscany, well known in history through her constant support of Pope Gregory VII. in his long struggle with the Empire, was a daughter of Boniface, Count of Tuscany, and of Beatrice of Lorraine, and was born in 1046. She married first Godfrey (surnamed the Hunchback), Duke of Lorraine, from whom she lived apart in Italy, and afterwards, when over forty years of age, the boy Guelf of Bavaria. Both marriages were mere alliances of policy. In 1077 she made a gift of all her vast possessions to the church, a bequest that caused a long contest. It was at her castle of Canossa that Henry IV. did his celebrated penance to Pope Gregory. Four years later she alone stood by the pope when Henry poured his troops into Italy; she supported him with money when he was besieged in Rome; and after his death at Salerno boldly carried on the war against the emperor. 'The great Countess' died in 1115. See *Life* by Nora Duff (1909).

Matins. See BREVIARY.

Matisse, HENRI, post-impressionist painter, was born in 1869 in the north of France. Influenced at first by Impressionism and then by Gauguin, he developed from an almost academic draughtsman into the chief of the Fauves (see PAINTING). His paintings—landscapes, figures, still-life—are notable for a sureness and simplicity of drawing, and for an arbitrary distortion of natural form, partly based on the study of negro art. Historically he is important as a pioneer of the doctrine that mere actuality is unimportant in pictorial representation; he marks a stage on the way, indeed, to the abstract non-representative art of the Cubists. He may also be regarded as the introducer of 'shock tactics' into art. His 'Head of a Woman' is a representative work.

Matlocks, THE, a Derbyshire urban district, 17 miles N. by W. of Derby, comprising Matlock, Matlock Bath, Cromford, and Tansley, which extend for about 3 miles along the romantic valley of the Derwent. Matlock is noted for its hydro-path and hydropathics. Matlock Bath has hot

springs of 68° F., the waters of which are largely charged with carbonic acid, and were first used for curative purposes in 1698. In the neighbourhood are the High Tor (400 feet), the Heights of Abraham (650 feet), and the Masson (1110 feet), and a number of large stalactite caverns with 'petrifying' wells. There are manufactures of cotton, paper, and spar ornaments, and bleaching, dyeing, woollen and hosiery works. Pop. 10,500.

Matoppo Hills, the watershed between the Limpopo and the Zambezi in which the Matabele tableland (itself rising to 4000 feet) culminates. Bulawayo is on their slopes, and among them Cecil Rhodes and Sir Starr Jameson were buried.

Matrah, a northern suburb of Muscat (q.v.).

Matriarchate. See FAMILY.

Matsumoto, a town of Honshu, Japan, 130 miles NW. of Tokyo, manufactures silks, baskets, and preserved fruits; pop. 40,000.

Matsushima, a pine-clad archipelago (over 800 islets) in Sendai Bay, E. coast of Honshu, is one of the three natural wonders of Japan.

Matsuyama, a town in the western part of Shikoku, Japan, 5 miles from its port, Mitsu, has a large feudal castle; pop. 50,000.

Matsuyce, a town in an inlet of the Japan Sea, 140 miles W. by N. of Kyôto, has large manufactures of paper; pop. 35,000.

Matsys, or MASSYS, QUENTIN, Flemish painter, born at Louvain about 1466, was said to have been a blacksmith who turned artist. He settled in Antwerp in 1491, was admitted a member of the painters' guild of St Luke in that city, and died there in 1530 or 1531. He was a link between the Van Eycks and the later Dutch school. His pictures are mostly religious, treated in a reverent spirit but with decided touches of realism, and are remarkable for their glow of colour, their absence of light and shade, and their exquisite finish, especially in minor details. An altarpiece for the cathedral of Antwerp—the 'Burial of Christ' flanked by the 'Martyrdom of John the Baptist' and the 'Martyrdom of John the Evangelist'—is his masterpiece. Such genre-pieces as 'The Money-changers,' 'The Gaoler,' and others, exhibit his realistic tendencies. Matsys also takes high rank as a portrait-painter. A beautiful wrought-iron well-covering at Antwerp is attributed to him.

Matter is that which moves from place to place, and which, when accessible, is amenable to our guidance and arrangement by an act of will interpreted and made effective by our nerve and muscle system. Matter reacts against muscular or other force, and by this reaction or resistance its presence is primarily known or inferred. It is the vehicle of kinetic energy whenever this is conveyed without change or alternation of form.

The term 'matter' by no means covers everything in the material universe, for neither sound, light, heat, electricity, nor ether, is matter, and yet these things are physical, and may be called 'material' in the sense of belonging to the material universe, and as antithetic to 'mental' and 'spiritual.'

The most fundamental property of matter is *inertia*, also called massiveness and *mass*, whereby it reacts against any force in direct proportion to the acceleration which it is made to undergo. Acceleration may be a simple increase of speed, or it may be the negative kind more commonly called retardation, or it may be a change in the direction of the velocity or a curvature of path. In all cases the resultant force which produces the effect is measured by the product of mass into acceleration, a fact which is called Newton's Second Law of Motion, and is the most fundamental

truth in mechanics. Of late years the electrical theory of matter, and the doctrine of Relativity (q.v.), have concurrently shown that inertia is not absolutely constant, as had been thought, but depends to a slight extent on speed; so that if matter moves at an excessive speed through the ether its apparent inertia is increased. The full consequences of this notable fact have not yet been worked out.

The common mode of measuring mass or inertia is by utilising the secondary property which matter possesses—that of mutual gravitative attraction between its parts. Every piece of matter attracts every other with a force which is extremely small between masses of ordinary humanly-manageable size, but which becomes important, and is known as *weight*, when one of the masses is enormous like the earth.

From the fact that every kind of matter if dropped to earth, in the absence of a resisting medium, falls at one and the same rate, Newton proved (most accurately by experiments on pendulums) that weight and mass are proportional; though the reason for this apparently exact correspondence is at present unknown, or only a matter of speculation. Nor has any satisfactory explanation been as yet given for the hourly encountered phenomenon of gravitational attraction itself. It is believed to extend throughout the universe, and it is believed that nothing can disturb or intercept it. Matter is supposed to be essentially indestructible. Certainly experience shows that whatever is done to a piece of matter, whether it be heated, or cooled, or dissolved, or evaporated, or corroded, or crushed, or burnt, or, in popular language, 'destroyed' in any way, it still weighs, as far as can be tested, precisely the same, and therefore presumably consists always of precisely the same fundamental substance. It may have combined with extra material, or it may have shed fractions of itself which cannot be collected, but what the doctrine of indestructibility asserts is that if all accretions were removed and every original fragment collected, the weight would be unchanged. This is indeed a special case of the meaning of *existence*, for anything of which such conservation can be predicated must have a real substantial or fundamental existence. Energy is in the same category in this respect, and these two things, matter and energy, are probably the only things in the material world of which such an assertion can be thoroughly made. Certainly no one asserts it of any particular *form* of energy, such as sound or heat; nor of any particular form of matter, such as uranium or radium; but of energy as a whole, and of matter as a whole, conservation is believed as an article of scientific faith. It is of course impossible to prove such things beyond the limits of refined experimental accuracy; but as the outcome of many experiments and much experience, these and other fundamental axioms or dogmas are confidently held by those who have made these phenomena a special study and therefore have a right to judge. But see concluding paragraphs of this article.

States of Matter.—Any particular kind of matter is determined by the chemical constitution of its atoms and molecules; but when in bulk it can make a different appeal to the senses, and to physical tests, according to the way in which the molecules are crowded together or are separate.

In the solid state, the molecules are joined or crystallised together so that no locomotion of parts is possible without dislocation or breaking, or without a resilient effort at recoil into some stable and less strained condition. This is called elasticity of shape, or *rigidity*.

In the liquid state no shape is fixed, the parts

are readily mobile, being restrained only by *viscosity*—a kind of friction which is proportional to speed, and which therefore becomes insignificant when the parts slide over each other slowly enough. Accordingly, a liquid adapts itself to the shape of the containing vessel. But the particles still cohere together, and therefore the liquid occupies a definite space or volume, and has a free or bounding upper surface. A liquid resists compression in an elastic manner, and this property is known as volume elasticity, or metrical incompressibility; a property which solids also intrinsically possess.

In the third or gaseous state the cohesion is greatly reduced, and locomotion of the parts is not only easy but is molecularly vigorous, and accordingly the gas or vapour adapts itself not only to the shape but also to the size of the containing vessel, and completely fills it. The amount of pressure which a given mass of gas exerts on the walls diminishes as the space occupied by it at a given temperature enlarges. When the diminution of pressure is exactly proportional to the increase of volume ($\frac{dp}{p} = -\frac{dv}{v}$) the liquid condition is completely departed from, and the gas is said to be 'perfect.' It is then said to obey Boyle's Law. So also when the expansion or contraction or distortion of a solid is exactly proportional to the strain which causes it, the substance is said to obey Hooke's Law, or to be perfectly elastic.

The volume elasticity of a perfect gas is not an intrinsic property characteristic of the material, but is simply equal to the pressure upon it; except when the compression is sudden, when by reason of the generation of heat the volume elasticity is greater than the pressure, by a factor which is an important constant, characteristic of the substance—characteristic, in fact, of the number of degrees of freedom which the molecule of the substance possesses. For a monatomic molecule the factor is, both theoretically and practically, $\frac{2}{3}$; for a diatomic molecule it is $\frac{5}{2}$; for a tri- or polyatomic molecule the factor is $\frac{3}{2}$; these numbers being reduced by any so-called 'imperfection' of the gas or cohesive force between its molecules. This factor is technically known as the ratio of the two specific heats, also as the ratio of the adiabatic to the isothermal elasticity; and it is measured experimentally by determining the velocity of sound in the gas, or, what is the same thing, the wave-length corresponding to a note of given pitch. In this way, such gases as argon and helium have been shown to be monatomic, whereas most familiar gases have two atoms in their molecule. An imperfect gas is often styled a vapour, and there is a gradation of properties from solid to liquid, investigated by Andrews of Belfast and Van der Waals of Holland, and expressible in various generalised forms of Boyle's Law. See MOLECULE.

The well-known fact that water can occur in all three states, as ice, water, and steam, is only typical of what is true of almost every substance. Certainly every substance can be solidified, but the conditions required by liquidity involve a rather delicate adjustment, since the freezing and boiling points of some substances are very close together; or the boiling-point may even be the lower of the two, in which case the liquid state is impossible. Again, there is a critical temperature for every substance, above which it cannot exist in the liquid state; or, rather, above which the liquid and gaseous states merge into one another so as to be indistinguishable. Most permanent gases are in this predicament, and cannot be liquefied by the extremest pressure unless they are at the same time cooled below the critical point. The critical

point for water is very high, approximating to a red heat, but water can be brought to it under sufficiently immense pressure.

Some solids would be decomposed or charred or otherwise chemically altered before they were hot enough to evaporate in bulk; though it is probable that every substance evaporates slightly, in the sense that a few molecules are constantly escaping from it; and this presumably accounts for the *smell* of nearly all substances. The escape of a few million molecules per second would hardly be noticeable to the most delicate weighing until after the lapse of hundreds of years.

The existence of the gaseous state, with its very special features, has enabled us to obtain great insight into the structure of matter. For experiment has assured us that a gas is not a continuous substance, but an assemblage of an enormous number of perfectly distinct and independent particles, each of which moves freely till it collides with another, and thus, some eight thousand million times per second, has its motion completely changed. The number of such separate particles in a single cubic inch of air contains twenty-one figures—i.e. is expressed in hundreds of trillions. Yet they are very far from filling that space. Their total bulk probably amounts to less than the five-hundredth part of it.

In vacuum tubes under electric discharge what Crookes described as a fourth or ultra-gaseous state of matter is experienced, a state which is of great interest. But J. J. Thomson proved that the particles flying with immense velocity in such tubes are not atoms of ordinary matter, but are corpuscles of incomparably smaller size. They are believed to be what Maxwell had already spoken of as atoms of electricity, and what Dr Johnstone Stoney had prophetically denominated Electrons (q.v.). There is every reason to believe that they are disintegrated from atoms of matter; they are found to be identical, whatever form of matter is their source; and there is some reason to suspect that they may re-group themselves, under conditions unknown, to re-form atoms again; in which case the various numbers and groupings would be expected to be capable of accounting for the various kinds of element, and with further discovery may be hoped to account for some of their chemical and physical properties. Their number in the respective atoms of the series of chemical elements has now been counted by Moseley, and less directly by Rutherford. The number ranges from 1 in hydrogen to 92 in uranium. The temporary element radium has 88. Several much more temporary elements are known, and it is uncertain if any atomic grouping is absolutely permanent. One element can change into another when one or more of its constituent electrons are expelled.

There is little or no doubt now that each atom of matter is composed of opposite electric charges; and a great deal has been discovered about the number and arrangement of these charges to form the different chemical atoms. This is too elaborate a subject to deal with here. Books, such as Sir Oliver Lodge's *Atoms and Rays*, may be consulted.

The electrical constitution of matter is only emphasised here in order to issue a caution about the conservation of matter, spoken of above. It seems possible that occasionally, perhaps only at very high temperatures, the positive and negative ingredients or constituents of an atom may meet and neutralise each other, thereby generating radiation or waves in the ether. If that ever happens, matter as such disappears; so that we might say, energy is conserved but not matter. According to the theory of relativity, indeed, matter is one of the forms of energy, which may conceivably be transmuted into other forms. It would not be

suitable here to enter into details about such apparently revolutionary ideas, but it is well to bear the possibility in mind. On this view matter may ultimately be resolvable not only into electric charges, as it is now, but into a special kind of intrinsic motion in the ether of space.

Mere speculation, of course, is of use in science only in so far as it originates or directs inquiry, so that we must be content simply to express the idea that the ether may be the one material substance in the universe (*urstoff*), gross matter being simply differentiated portions of it—denser or less dense than the rest, perhaps mere cavities or bubbles. For the extreme form of the electro-magnetic theory—that matter ultimately consists of particles of electricity—see Sir J. J. Thomson's *Corpuscular Theory of Matter* (1907), Sir Ernest Rutherford's *Radioactive Substances* (1913), and other works.

Matterhorn, called by the French MONT CERVIN, and by the Italians MONTE SILVIO, a peak of the Alps between the Swiss canton of Valais and the Italian compartment of Piedmont, rises to the altitude of 14,705 feet. The actual peak was first scaled by the Englishmen Lord Francis Douglas, Hudson, Hadow, and Whymper, with three guides, in July 1865, when the three first-named were lost. See Whymper's *Matterhorn* (1880) and *Zermatt* (1897), and Guido Rey's *Il Monte Cervino* (1904; trans. as *The Matterhorn*, 1907).

Matthew, one of the apostles and the reputed author of the first gospel. Little is known about him apart from the few references in the gospels. He was originally a revenue officer at Capernaum (Matt. ix. 9), but was called by Jesus 'at the customs house' to become his disciple. In Mark and Luke his name is given as Levi, but there is no reason for doubting the identification of the two names, as in each case the man is described as 'the son of Alphaeus,' and represented as engaged in the same business. Double names frequently occur in the New Testament—e.g. John Mark, Barnabas Justus, 'Saul, who is also called Paul.' On the day of his call Matthew gave what was probably a farewell banquet to his friends, at which Jesus was present. His name appears in all the lists of 'the twelve,' and occupies either the seventh or eighth position. Tradition represents him as an evangelist, but no reliance can be placed upon the details which are given of his work in apocryphal literature. Nor can we attach any importance to the statement that he suffered martyrdom, in view of the explicit denial in the writings of Clement of Alexandria.

The earliest writer to connect Matthew with the first gospel is Papias, who says: 'Matthew composed the Oracles in the Hebrew dialect, and each one interpreted them as he was able.' The tradition that Matthew wrote in Hebrew or Aramaic is afterwards repeated by Irenæus, Pantænus, Origen, Eusebius, Jerome, and many others. Modern criticism, however, challenges this position. The Gospel of Matthew is not as it stands a translation from the Hebrew. Papias's description of Matthew's work as 'the Oracles' or 'Logia' does not seem appropriate to our gospel, though instances have been adduced where the word is loosely applied to books which are mainly narrative. On the whole, the majority of modern scholars adopt the theory that what Matthew wrote was not our present gospel, but the Logia source which has been embodied in it.

Our gospel is obviously based upon sources (see GOSPELS), and makes free use both of Mark and the Logia source known as Q. It has, however, well-marked characteristics of its own. There is

ample evidence that it was originally addressed to the Jewish people. The great stress which is laid upon the argument from prophecy in the opening chapters is a clear indication that the author was attempting to commend Christianity to his Jewish friends. The argument from prophecy was the sheet-anchor of early apologetics, and the Gospel of Matthew affords us some of the best illustrations as to the manner in which the method was applied. The writer always, too, speaks from the Jewish standpoint. He nearly always uses the phrase 'kingdom of heaven,' for instance, in place of Luke's 'kingdom of God.' And it is only in Matthew that the favourable attitude of Jesus to the Jewish law is mentioned (v. 17), and it is only Matthew who records the saying of Jesus in the commission to the twelve, 'Go not into any way of the Gentiles, . . . but go rather to the lost sheep of the house of Israel.' The date of the gospel is difficult to determine, because the data are insufficient and insecure. Many scholars think that the eschatological discourses point to a date earlier than the destruction of Jerusalem in 70 A.D. In speaking of the fate which is to befall the city Matthew uses the phrase of Daniel, 'the abomination of desolation,' and adds the note, 'Let him that readeth understand.' If the destruction of Jerusalem had already occurred, it is probable that this phrase would have been modified by the event, as it has been modified in Luke. This argument, however, is not final, because it is just possible that the author of Matthew may have repeated the version of the prophecy of Jesus as it had come down to him, and did not feel at liberty to alter it at all. The arrangement of the gospel is artificial when compared with that of the other synoptics. Matthew arranges his material in blocks. Thus we have groups of miracles, sayings, parables, &c.; and there is no attempt to write a chronological narrative.

The best modern commentaries are those of Plummer, M'Neile, and Allen in English; and Wellhausen, Zahn, Holtzmann, Gressman, and J. Weiss in German.

Matthew of Westminster, long supposed to be the author of the meritorious *Flores Historiarum*. Sir F. Madden considered his existence as more than doubtful, the work being merely a special abridgment of the larger work of Matthew Paris, made under that writer's supervision down to 1249; brought down at St Albans to 1259, at which year Paris's chronicle ends; thereafter continued there down to 1265; next brought down to 1325 at Westminster, in part by John Bever, *alias* John of London. Sir T. D. Hardy, however, thinks it based on the original writer who preceded Wendover as historian at St Albans, whom he identifies as one Walter of St Albans, precentor and librarian in the latter half of the 12th century. Copies of his chronicle would become disseminated, and that at Westminster, by its borrowings from the works of Wendover and Matthew Paris, might well have been taken for a mere abridgment of these. Luard finally demolished the hypothetical author in his edition of the *Flores* (Rolls Series, 1890). A translation by Yonge was published in 1853.

Matthew Paris. See PARIS.

Matthias Corvinus, king of Hungary, the second son of John Hunyady (q.v.), was born at Klausenburg probably in 1440. His father having died, his elder brother was slain and himself imprisoned by order of Ladislaus Posthumus, king of Hungary and Bohemia. After the death of this king Matthias was elected by the magnates to the vacant throne (1458). But it cost him a six years' hard struggle against Turks, Bohemians, the Emperor Frederick III., and disaffected mag-

nates before he could venture to have himself crowned at Stuhlweissenburg. He drove the Turks back across the frontiers of his kingdom, and made himself master of Bosnia (1462), and of Moldavia and Wallachia (1467), before he granted them a truce. This breathing-space Matthias employed in making war upon Podiebrad, king of Bohemia, his own father-in-law, whose crown had been offered to him by the pope. Podiebrad died in 1470, but the war was continued against his successor, Ladislaus of Poland. In the midst of the war the magnates rebelled, because their king disregarded their political rights and influence, and offered his throne to Casimir, brother of Ladislaus. But Matthias managed to appease them, and in 1478 he concluded peace with Ladislaus, obtaining Moravia, Silesia, and Lusatia. Out of this war grew another with Frederick III., in which Matthias besieged and captured Vienna (1485). This he made his capital, and two years later he took possession of a large part of Austria proper. Since 1469 the Turks had renewed their terrible invasions of Hungary; but at length in 1479 they met with just chastisement, at Kenyermezö, at the hands of Stephen Bathori of Transylvania. But Matthias, who died at Vienna on 6th April 1490, was more than an ambitious conqueror. He greatly encouraged arts and letters: he founded the university of Buda, built an observatory, summoned scholars and artists to his court, adorned his capital with the works of renowned sculptors, employed a staff of literary men in Italy to copy valuable manuscripts, and so founded a magnificent library. This was scattered when the Turks captured Budapest in 1526. The surviving books were restored by the sultan in 1877. Besides all this the finances were brought into a flourishing condition, industry and commerce were promoted by wise legislation, and justice was administered strictly to peasant and noble alike. But his rule was arbitrary and his taxes heavy; he wasted much money in pompous display; and he overrode the rights of the magnates.

Matto Grosso ('dense forest'), an inland state of Brazil, bordering on Bolivia; it is second to Amazonas alone, both in size and sparsity of population. Area, 532,000 sq. m.; population, 247,000, nearly all Indians and blacks. Within this vast territory several great rivers rise, including the Madeira and the Paraguay; but in most parts there is a scarcity of water during the dry season. The vegetation is generally scanty, grass, bush, and low trees covering the sandstone plateau; high trees and rich vegetation are confined to the river valleys. The gold and diamonds which formerly constituted the wealth of Matto Grosso have been exhausted, and agriculture (insufficient for the wants of the state) and cattle-raising, with the gathering of medicinal plants by the Indians, are now the principal industries; but manganese is mined. The capital is Cuyabá (q.v.). The former capital, Matto Grosso, on the Guaporé, decayed with the gold-mining industry.

Mattoon, a city of Illinois, 160 miles S. by W. of Chicago. It contains railway-shops, flour-mills, and grain-elevators, and manufactures castings and drain tiles. Pop. 13,500.

Maturin, CHARLES ROBERT, dramatist and romancer, was born in 1782, waged warfare with poverty as curate of St Peter's, Dublin, and died there, 30th October 1824, after making his name at least notorious by a series of extravagant novels that outdid Mrs Radcliffe. These were *The Fatal Revenge*, *The Wild Irish Boy*, *The Milesian Chief*; and, later, *Women*, *Melmoth* (most famous and most hyperbolic of them all), and *The Albigenes*. His tragedy, *Bertram*, had a success at Drury Lane in 1816; its successors, *Manuel* and *Fredolpho*, were promptly damned.

Maubeuge, a fortified town in the French department of Nord, 4 miles from the Belgian frontier, was in German hands during the Great War; pop. 21,000.

Mauch Chunk, a mining-town of Pennsylvania, capital of Carbon county, is situated among picturesque hills on the Lehigh River, 70 miles NNW. of Philadelphia. There is a switch-back railway, 9 miles long, from the town to Summit Hill—famous for its ‘burning mines,’ smouldering since 1858. Pop. 4000.

Mauchline, a town of Ayrshire, 12 miles ENE. of Ayr, and 10 SSE. of Kilmarnock. It has long been noted for its wooden snuff-boxes and similar nicknacks. There is a monument (1830) to five martyred Covenanters; and 1 mile N. is Moss-giel, Burns’s farm from 1784 till 1788; whilst in the village itself are ‘Poosie Nancy’s,’ the scene of his *Jolly Beggars*, and Mauchline kirk, of his *Holy Fair*. Pop. 1500.

Maud. See MATILDA.

Maude, SIR FREDERICK STANLEY (1864–1917), British soldier, educated at Eton and Sandhurst, served in the Sudan and South Africa, was military secretary to the governor-general of Canada (1901–4), and later was employed at the War Office. In the Great War he commanded a brigade in France, took part in the Gallipoli evacuation, and becoming commander-in-chief in Mesopotamia, soon turned failure into complete success, culminating in the taking of Bagdad, where he died of cholera. See WAR (GREAT), and Life by Callwell (1920).

Maudsley, HENRY, a prominent student of mental pathology, was born near Giggleswick in the West Riding of Yorkshire, 5th February 1835, and was educated at Giggleswick grammar-school and University College, London. He graduated M.D. at the university of London in 1857, was for a time physician to the Manchester Royal Lunatic Asylum, but returned to London in 1862 to be a consulting physician. From 1869 to 1879 he filled the chair of Medical Jurisprudence at University College. He published, besides minor works, *The Physiology and Pathology of the Mind* (1867), *Responsibility in Mental Disease* (1872), *Body and Will* (1883), *Natural Causes and Supernatural Seemings* (1886); and, still materialist and teleologist, *Life in Mind and Conduct* (1903), and *Organic to Human* (1916). He died 23d January 1918.

Maugham, WILLIAM SOMERSET, English novelist and playwright, born at Paris in 1874, was educated at Heidelberg, and became a physician and surgeon at St Thomas’s Hospital, London. Since his first novel, *Liza of Lambeth* (1897), he has used the scalpel on the human mind. The better known of his novels include *The Making of a Saint* (1898), *The Moon and Sixpence* (1919), and *The Painted Veil* (1925), a powerful portrayal of conditions in China. It is his plays, however, which have brought him most fame. Among the chief are *Lady Frederick* (1909); *The Tenth Man* (1910); *The Circle* (1921), by many considered his best; *East of Suez* (1923), a melodramatic presentation of the old problem of East and West; *Our Betters* (1923); *The Camel’s Back* (1924); and *Rain* (1925), a powerful if sordid drama. A trail of tragic experience, apt to become monotonous, runs through all Maugham’s work, and irony is perhaps his most marked characteristic, although humanity cannot be denied to his creations. Some of his plays are cynical and light.

Maulmain, or MOULMEIN, a town in the division of Tenasserim, Burma, near the mouth of the Salwin River. It is backed by a fine range of hills, on whose heights flash the gilded spires of innumerable pagodas; and there, too, are built

many pretty residences, commanding a fine view of the town, river, and adjacent country, which for picturesque beauty and varied scenery has few equals. There are numerous public buildings, churches, chapels, and missionary establishments, several charitable and educational institutions, barracks, a hospital, and jail. The population is about 61,000, consisting, besides Burmese, of Hindus, Malays, Europeans, Anglo-Indians, Chinese, Armenians, and Jews. The principal exports are teakwood and rice; the imports consist of general merchandise, chiefly piece-goods, hardware, provisions, and sundries. See BURMA.

Mauna Loa, a great volcano in Hawaii (q.v.).

Mauder, SAMUEL, compiler, was born about 1785, and died 30th April 1849. He was a brother-in-law of William Pinnock, assisted him in the preparation of his catechisms, and amongst other works which he compiled are *Biographical Treasury*, *Scientific and Literary Treasury*, *Treasury of Knowledge*, *Treasury of History*, &c. These books have been frequently revised and reissued.

Maundeville. See MANDEVILLE.

Maundy-Thursday, the Thursday of Holy Week (q.v.). The name *Dies mandati* is derived from the ancient custom of washing the feet of the poor on this day, and singing at the same time the anthem *Mandatum novum*, which is taken from John, xiii. 34. This rite, called *mandatum* or *lavapedum*, is of great antiquity, both in the Eastern and Western churches. In more modern times it came to be accompanied by a distribution of ‘doles,’ placed in small baskets, thence called ‘maunds.’ In the royal usage of the maund in England, the number of doles distributed is reckoned by the years of the monarch, and their value is 1d. for each year of the sovereign’s life. James II. was the last English sovereign who performed this ceremony in person; but the Austrian emperor, Francis Joseph, continued the custom from 1849 till 1888, washing every year the feet of twelve old men. In Madrid the ceremony is retained, the feet of twelve old men and twelve old women being touched with a sponge and towel by the sovereign, who afterwards serves them at table; and in 1889 the feet of twelve boys were washed in the Roman Catholic pro-cathedral at Kensington by one of the bishops, each boy also receiving a piece of money. During the middle ages the maund was held in all monasteries and great houses; and in the Household Book of the Earl of Northumberland, which begins in 1512, there are entries of ‘al maner of things yerly yevin by my lorde of his Maundy and my laidis and his lordshippis childeren.’ See Skeat’s edition of *The Vision of Piers the Plowman* (vol. i. p. 488, l. 140, note).

Maupassant, GUY DE, a clever French writer, was born 5th August 1850, at the castle of Miromesnil in Normandy, and, after carrying a musket through the Franco-German war, was initiated by Gustave Flaubert into the craft of letters. He attached himself to the younger branch of the naturalistic school, and wrote himself in by a story contributed to the *Soirées de Médan* (1880). He next produced a play, *Histoire du Vieux Temps*, and a striking volume of lyrics published under the title *Des Vers* (1880). But he won his real reputation as a novelist and storyteller, with *La Maison Tellier* (1881), *Les Sœurs Rondoli* (1884), *Contes du Jour* (1885), *Contes et Nouvelles* (1885), *Monsieur Parent* (1885), *Bel-Ami* (1885), *La petite Roque* (1886), *Pierre et Jean* (1888), and *Fort comme la Mort* (1889). He became insane in 1892, and died in an asylum, 6th July 1893.

Maupertuis, PIERRE LOUIS MOREAU DE, mathematician, was born at St Malo on 17th

July 1698, and after five years in the army devoted himself to science. His able advocacy of Newton's physical theory, in opposition to that of Descartes, gained him admittance to the Royal Society of London in 1728. In 1736-37 he was placed at the head of the Academicians whom Louis XV. sent to Lapland, to obtain the exact measurement of a degree of longitude, whilst the same thing was being done in Peru by La Condamine. This operation Maupertuis described in *De la Figure de la Terre* (Paris, 1738). In 1740 he went to Berlin, on the invitation of Frederick II., who made him president of the Academy. Having accompanied the Prussian army to the field, he was taken prisoner at Mollwitz by the Austrians in 1741. He returned to Berlin in 1744; but his morbid *amour-propre* and tyrannical disposition excited general dislike. Besides being engaged in a bitter quarrel with König as to the merits of Leibniz, he incurred the enmity of Voltaire, who satirised him in *Micromégas* and *Diatribes du Docteur Akakia*, whereby Maupertuis was driven away to Basel to recoup his health, and to enjoy the society of the Bernouillis, but he died there, 27th July 1759. Maupertuis was a mathematician of good ability, but owed his celebrity as much to the idiosyncrasies of his manners and disposition as to his merit. His *Works*, 4 vols., appeared at Paris in 1752, and at Lyons in 1768. See *Life* by La Beaumelle (1856) and Lesueur (1897).

Maurepas, JEAN FRÉDÉRIC PHELYPEAUX, COMTE DE (1701-81), a French statesman, born at Paris. He was brought up for public life, and was early entrusted with office, but contrived to displease the all-powerful Pompadour, and was banished from court in 1749. He was recalled and made first minister at the accession of Louis XVI. (1774), and, by helping the American colonists in their war for independence, he succeeded in his policy of humiliating England; but his was not the hand to hold the helm in the face of fast-gathering storms. Yet he brought into the ministry men far greater and wiser than himself—Turgot, Malesherbes, and Necker. His secretary, Sallé, edited his *Mémoires*.

Mauretania, Maurétanie. See MAURITANIA.

Maurice, PRINCE OF ORANGE and COUNT OF NASSAU, one of the most skilful generals of his age, was the son of William the Silent, Prince of Orange, and was born at Dillenburg, 13th November 1567. After his father's assassination in 1584, the provinces of Holland and Zealand, and afterwards Utrecht and the others, elected him their stadtholder. A great portion of the Netherlands was still in the hands of the Spaniards; but, under the admirable leadership of Maurice, the Dutch, aided by an English contingent under the Earl of Leicester and Sir Philip Sidney, rapidly wrested cities and fortresses from their enemies. In 1590 Breda, and in 1591 Zutphen, Deventer, Nimeguen, and other places fell into their hands, in 1593 Geertruidenberg, and in 1594 Groningen. In 1597 he defeated the Spaniards at Turnhout in Brabant, and in 1600 won a splendid victory at Nieuwpoort. Then for more than three years he baffled all the power of Spain by his defence of Ostend. Finally, in 1609, Spain was compelled to acknowledge the United Provinces as a free republic. But from this time keen dissension grew up between the Orange party, who favoured the Gomarists, and the Remonstrants or Arminians, who found their chief supporters in aristocratic republicans like Olden Barneveldt (q.v.; see also ARMINIUS). The former emerged victors from the struggle, and Maurice at once (1621) renewed the war with Spain. He died, unmarried, at The Hague, 23d

April 1625. See Groen van Prinsterer, *Maurice et Barneveldt* (Utrecht, 1875).

Maurice, JOHN FREDERICK DENISON, one of the most influential thinkers and social reformers of his age, was the son of a Unitarian minister, and was born at Normanston, near Lowestoft, 29th August 1805. In 1814 the family removed to Frenchay, near Bristol; and in 1823 he went up to Trinity College, Cambridge, thence migrating to Trinity Hall. His reputation at the university for scholarship stood high, but, being at this time a dissenter, he left Cambridge in 1827 without taking a degree, and commenced a literary career in London. He wrote a novel, *Eustace Conway*, and for a time edited the *Athenæum*, then recently started. His spirit had, however, been profoundly stirred and influenced by Coleridge, and he resolved to take orders in the Church of England. He proceeded to Oxford, where he took the degree of M.A., and was ordained a priest in 1834. He became chaplain to Guy's Hospital in 1837; in 1840 professor of Literature at King's College, London, where he was professor of Theology from 1846 till 1853. In 1846 he was appointed chaplain of Lincoln's Inn, and left Guy's Hospital. He continued chaplain of Lincoln's Inn until 1860, when he accepted the incumbency of Vere Street Chapel, which he held until his election as professor of Moral Philosophy at Cambridge in 1866. He died in London on 1st April 1872, and was buried at Highgate. The publication in 1853 of his *Theological Essays*, in which he dealt with the difficulties which hinder the acceptance of faith in Christ, lost him the professorship of Theology in King's College. The controversy turned on the doctrines of the atonement and eternal life. The atonement he declared to be not a terrible necessity but a glorious gospel, not of pardon for sin but deliverance from sin (see ATONEMENT); while Christ's definition of life eternal he maintained was opposed to the popular doctrine, which he regarded as a mixture of paganism and Christianity. The views set forth in this and other works were mainly these: that Christ was not the founder of 'a religion,' but king of all men, ruling now where he least seems to rule; that Christ's church does not consist of a few privileged persons, but is the body which represents 'the marriage of the Lamb,' that marriage being the incarnation, or uniting of the Godhead with manhood; that the 'fall of Adam' is not the centre of theology, but an incident in the early education of the race, important only as representing the weakness of man apart from Christ, in whom he lives and moves and has his being; that the curse of Adam was the condemnation of the false position of the man apart from God, resting on his own strength; that Christ came preaching 'the kingdom of heaven,' that is, the actual reign of righteousness in the world, the revelation of which is not contained in a closed book, but is always going on, and looks not backward to the restoration of an Eden of tropical fruits and easy culture, but forward to the cultivation by work and rest of all man's faculties unto the measure of the stature of the fullness of Christ; that faith consists in trust in this King of men, and belief in the power of right and the impotence, despite its seeming strength, of evil, not in the acceptance of formulæ: that creeds, the Bible, the church, are valuable just in so far as they set forth Christ the King as the object of the faith of man; as substitutes for that faith they are only mischievous. His principal books are his *Moral and Metaphysical Philosophy*, *Religions of the World*, *Prophets and Kings of the Old Testament*, *Patriarchs and Lawgivers of the Old Testament*, *The Kingdom of Christ*, *The Doctrine of Sacrifice*, *Theological Essays*, *Lectures on the*

Ecclesiastical History of the First and Second Centuries, Gospel of St John, The Conscience, and Social Morality. Maurice strenuously controverted Mansel's views on our knowledge of God, and denounced as false any political economy founded on selfishness and not on the Cross as the ruling power of the universe. He was the mainspring of the movement known as Christian Socialism, and the president of the society for promoting working-men's associations; and was also the founder and first principal of the Working-man's College, and the founder and the guiding spirit of the Queen's College for Women, in both of which he taught. He vehemently repudiated the position of a party-leader, and his influence consequently extended throughout all parties in the church. He denounced the whole party-system as tending to divide Christ's body, both in church and state. See the *Life* (1884), based mainly on his letters, by his son, Major-general Sir J. F. Maurice (1841-1912), a distinguished soldier and lecturer and author on military history, including the history of the South African War.

Maurice. See BYZANTINE EMPIRE; CHARLES V.; RUPERT; and SAXE.

Maurier. See DU MAURIER.

Maurists, a reformed congregation of Benedictines, originally established in Lorraine, but from 1618 onwards named after the 6th-century St Maur, and established at the abbey of St-Maur-sur-Loire, 14 miles NW. of Saumur. Originally noted for their austerity, they were afterwards especially known for their services to learning. The headquarters of the order was subsequently in three houses near Paris, especially St-Germain-des-Prés. The congregation was dissolved with other monastic orders in 1792, and the splendid conventual buildings at St Maur destroyed during the revolutionary troubles. Amongst the learned fathers of St Maur were such scholars as Mabillon, Montfaucon, D'Achéry, Martène, Rivet, Tassisi, Bouquet, Ruinart, Lami; and amongst the works published, besides admirable editions of the fathers, the *Art de Vérifier les Dates* (1750), a new edition of Du Cange's *Glossarium, De Re Diplomatica, Acta Sanctorum S. Benedicti* (9 vols. 1668-1702), *Annales Ordinis S. Benedicti* (6 vols. 1703-39), *Gallia Christiana, Veterum Scriptorum Amplissima Collectio, Histoire Littéraire de France*, &c.

Mauritania, or MAURETANIA, the ancient name of Morocco and western Algeria, was derived from its inhabitants, the Mauri or Maurusii (see MOORS). It reached on the south to the Atlas Mountains, and was originally separated from Numidia by the river Mulucha, now the Muluya, though later it extended as far east as the Ampsaga. In ancient times it yielded great quantities of corn and valuable timber. See MOROCCO. The modern Maurétanie, a French colony since 1921, lies farther south, between Morocco and Senegal. Area, 347,400 sq. m.; pop. 262,000, mostly nomad Moors.

Mauritius, or ISLE OF FRANCE, an island in the Indian Ocean, belonging to Great Britain, and situated 550 miles E. of Madagascar. Area, 720 sq. m. It is of volcanic origin and elliptical in shape. A girdle of reefs, broken only by passages opposite the mouths of the small streams, renders it somewhat difficult of approach. The contour rises rapidly into a tableland that shoots up into ridges 500 to 2700 feet in height. Of individual peaks, Pouce (2650 feet) resembles the human thumb, Pieter Botte (2676), a sharp cone, supports a gigantic crag on its summit, and Rivière Noire (2711) is the culminating point of the island. Lavas abound, and volcanic lakes, as Grand Bassin, are not uncommon. During the French occupation (1715-1810) Mauritius, or, as they

called it, Île de France, was well wooded. Its picturesque beauty forms the appropriate background of Bernardin de St Pierre's idyl, *Paul and Virginia*, and is well described in Besant and Rice's novel, *My Little Girl*. But during the 19th century the forests were cut down to make room for sugar-cane plantations. Consequently but little of the native flora remains. The more conspicuous trees and plants are the ebony-tree, coconut and other palms, bamboo, benzoin, ironwood, aloe, traveller's tree, and numerous tropical fruits, besides food plants, such as sugar, vanilla, coffee, cocoa, maize, rice, yams, manioc, &c. The existing fauna consists almost entirely of imported domestic animals. The extinct fauna embraced the interesting Dodo (q.v.), the rail called Aphanapteryx, and a short-winged heron. Fossil tortoises of great size have been discovered. The birds resemble those of Madagascar; and the neighbouring seas swarm with fish. Owing to the deforesting of the island the rainfall is uncertain. Though pleasant enough in the cool months, the climate, except in the elevated plains of the interior, is very hot during the rainy season (December to April or May), and terrific cyclones are common, though less common, it is believed, since the woods have been felled. In 1854 cholera carried off 17,000 people, and thirteen years later 30,000 perished of a malignant fever. The upper classes, very intelligent, cultured, and well educated, are mostly descended from the old French colonists, except that the government officials, with a few others, are English. There is a large number of half-castes, and a considerable body of Negroes, Malagasy, Singhalese, Malays, Chinese, &c. But the greater part of the population consists of Indian coolies, who work the sugar-fields. Pop. (1881) 359,874; (1921) 376,680, of whom 265,884 were Indians. The people of European origin are mostly Roman Catholics (some 122,000), though there are also about 1000 Protestants; the Indians are mostly Hindus. The chief towns are Port Louis (q.v.), the capital, on the north-west coast, partly ruined by the destructive cyclone of April 1892; Curepipe, to which the government and merchants of the capital retire in the hot season; and Mahébourg. From Port Louis railways run round the northern half of the island, across to the east, and by way of Curepipe to the south and south-east (Mahébourg). The one great crop and export of the island is sugar. Aloe fibres (known in commerce as Mauritius hemp) and coconut oil are also exported. Cotton goods, iron and steel manufactures, soap, machinery, &c., are imported. The crown colony of Mauritius, with its dependencies Rodriguez (q.v.), Diego Garcia (q.v.), and several minor islands—total area, 90 sq. m.; pop. 8400—is administered by a governor, aided by an executive council; the Seychelles were made a separate colony in 1903. There is also a Council of Government, consisting of the governor and twenty-seven members, of whom ten are elected, nine are nominated by the governor, and eight are *ex officio*. Port Louis is fortified. Education is free, but not compulsory. Besides primary schools, there is the Royal College for secondary education, as well as other secondary schools. There is a Roman Catholic bishop of Port Louis, and a Protestant bishop of Mauritius. The European discovery of the island was made by the Portuguese between 1506 and 1528, tradition says by Mascarenhas (whence it and the neighbouring islands are called the Mascarenes); at that time it was uninhabited. The Portuguese having abandoned it after ninety years' possession, it was seized by the Dutch in 1598, who named it after their Prince Maurice (q.v.); but they in their turn abandoned it in 1710. It was the French governor Mahé de Labourdonnais (1735-46) who established the sugar-growing

industry, and laid the foundation of its prosperity. During the Napoleonic wars the privateers of Mauritius worked mischief on British shipping, and the island was occupied by Britain in 1810, and in 1814 was definitely acquired by her by the Treaty of Paris. Theodore Hook was treasurer in 1812-18. Under the British slavery was abolished in 1835, and in 1885 the first of various measures of representative government was introduced. At the time of the occupation Britain agreed to the retention of the existing laws, customs, religion, and Mauritius in consequence continued largely French in language and habits; after the Great War, however, an agitation by a section of the Europeans of French descent for the retrocession of the island to France met with no more than limited support.

See works by Grant (1801), Flemyng (1862), Ryan (1864), Boyle, J. G. Baker, G. Clark, Keller, Macmillan (1914), and Hart (1921); Bruce in *Scot. Geog. Mag.*, Feb. 1908; S. B. de Burgh-Edwardes, *History of Mauritius* (1922).

Maurocordatos, or MAVROCORDATO, a Fanariote family, distinguished for ability and political influence, and descended from Greek merchants of Chios and Constantinople.—ALEXANDER MAUROCORDATOS (circa 1637-1709), doctor of philosophy and of medicine of Bologna, became dragoman or interpreter to the Porte in 1681, rendered valuable service in negotiations with Austria, and drew up the treaty of Carlovitz (1699), becoming for a time one of a triumvirate in whose hands all power in the Ottoman empire rested.—His son, NICHOLAS (1670-1730), was the first Greek who was hospodar of Moldavia and Wallachia.—CONSTANTINE, son of Nicholas, became hospodar of Wallachia in 1730, and abolished serfdom in that country.—His brother's grandson, ALEXANDER MAUROCORDATOS, born at Constantinople on 15th February 1791, took an active part in the Greek struggle for liberty, and prepared the declaration of independence and the plan of a provisional government, being himself elected president of the executive body. In 1822 he undertook an expedition to Epirus, which ended in his defeat at Peta; but he saved the Peloponnesus by his resolute defence of Missolonghi (1822-23). In the subsequent strife of factions he continued to labour earnestly in the cause of Greek independence and union, but incurred unpopularity through his English sympathies and his opposition to the 'Russian' party. After the accession of King Otho he was at different times cabinet-minister and ambassador of Greece at various courts. At the outbreak of the Crimean War he was placed once more at the head of the government, but soon resigned. He died at Ægina, 18th August 1865.

Maurras, CHARLES, French writer, was born in 1863 at Martigues, and educated at the Catholic College of Aix. Coming to Paris he found work in journalism, literary criticism and politics being his themes. Intellectually he had been powerfully influenced by Comte and the classics, and in 'order' claimed to find the ideal in art and in government. In criticism he stood opposed to romanticism, and in the *Gazette de France* and other journals made a classical renaissance his aim. In politics, a nationalist first and last, he assailed the democratic ideas of his time, and in the interests of decentralisation, in the *Action Française* (a monthly reorganised by him in 1899 and changed into a daily in 1908), the *Figaro*, and other prints, championed a return to the hereditary monarchy. Among representative works are *Jean Moréas* (1891); *Trois Idées politiques: Chateaubriand, Michelet, Sainte-Beuve* (1898); *L'Enquête sur la Monarchie* (1900); *Anthinea* (1901), an account of a trip to Greece,

Italy, Corsica; *L'Avenir de l'Intelligence* (1905); *Le Dilemme de Marc Sangnier* (1906), an essay on religious democracy; *Kiel et Tanger* (1910); *Athènes antique* (1918). Maurras is recognised as one of the foremost French prose-writers of his day. His essays in poetry, as *Inscriptions* (1921) and *La Langue Intérieure* (1925), are of little merit. There are works on him in French by Descoqs (1913), Truc (1917), Ségard (1919), Thibaudet (1920).

Maury, JEAN SIFFREIN, French orator and prelate, was born on 26th June 1746 at Valréas (dept. Vaucluse), and his studies completed at Avignon, he went to Paris. Eloquent *éloges* on the dauphin, Charles V. of France, St Louis, St Vincent de Paul, and others, gained him the abbacy of Frinade, and in 1784 admission to the Academy. In 1786 he was made prior of Lihons-en-Santerre, and in 1789 was sent by the neighbouring clergy to the States-general, where as an orator he rivalled Mirabeau. At the dissolution of the Constituent Assembly he withdrew from public life, and even from France. The pope, admiring his devotion to Louis XVI., made him Archbishop of Nicæa in *partibus*, and cardinal in 1794; but in 1804 Maury made his submission to Napoleon, who in return appointed him Archbishop of Paris (1810). This step cost Maury the favour of the pope; that of the Bourbons he had of course already lost, and three years after their restoration he died in disgrace, 11th May 1817. Maury wrote *Essai sur l'Éloquence de la Chaire* (2 vols. 1810), 'one of the best books in the language'; his *Œuvres Choisies* were published in 5 vols. in 1827. See Lives by his nephew, L. S. Maury (1827), Poujoulat (1835), and Ricard (1887); also Sainte-Beuve, *Causeries du Lundi*, vol. iv.

Maury, MATTHEW FONTAINE, hydrographer, was born near Fredericksburg, Virginia, 14th January 1806. In 1825 he entered the United States navy, and during a voyage round the world commenced his well-known *Navigation* (1834). Lamed for life in 1839, he was appointed superintendent of the Hydrographical Office at Washington (1842), and of the observatory (1844). Here he wrote his *Physical Geography of the Sea* (1856), and his works on the Gulf Stream, Ocean Currents, and Great Circle Sailing. On the outbreak of the Civil War he joined the Confederate navy, and became head of land defences. Afterwards he occupied the chair of Physics in the Virginia Military Institute at Lexington, where he died 1st February 1873. There is a Life (1888) by D. F. Maury Corbin, his daughter.

Mausoleum, a sepulchral monument of large size containing a chamber in which urns or coffins are deposited. The name is derived from the tomb erected in 353 B.C. at Halicarnassus (q.v.) to Mausolus, satrap of Caria, by his widow (and sister), Artemisia. It was esteemed one of the seven wonders of the world. Although apparently in good condition as late as the 12th century, it fell into decay during the following two centuries. The ruins were ransacked for building materials by the Knights of St John in the 16th century. The site was rediscovered in 1857 by Newton, who was instrumental in getting the remains carried to the British Museum (q.v.). The mausoleum consisted of a basement 65 feet high, on which stood an Ionic colonnade 23½ feet high, surmounted by a pyramid, rising in steps to a similar height, and on the apex of that stood a colossal group, about 14 feet in height, of Mausolus and his wife in a *quadriga*; these statues are supposed to have been the work of the celebrated Scopas. Later instances of large and magnificent mausoleums are Metella's tomb, Hadrian's (Castle of San Angelo), and that of

Augustus, all at Rome, the mausoleum of Frederick-William III. and Queen Louisa at Charlottenburg, that of the House of Hanover at Herrenhausen, of the Prince Consort and Queen Victoria at Frogmore in Windsor Park, of Napoleon III. at Farnborough, of A. T. Stewart at Garden City (q.v.), not to speak of Lick Observatory (q.v.) and other American monumental erections. See **BURIAL**.

Mauvaises Terres, or **BAD LANDS**, extensive waste lands of the western United States consisting of soft horizontal strata deeply eroded into fantastic architectural and other forms; at a little distance they appear like fields of ruins. The name was first applied to a Tertiary (Miocene) area in the region of the Black Hills in South Dakota along the White River, but there are similar lands in Colorado, Arizona, New Mexico, Texas, and elsewhere.

Mauve, **ANTON** (1838-88), Dutch landscape painter, born at Zaandam, was chiefly self-taught. With Israëls and Jakob Maris he is in the front rank of modern Dutch artists. He painted in both oil and water colours. 'The Sand Cart,' 'The Flock of Sheep,' 'The Flock Returning,' 'On the Heath,' and 'Evening' are among his best pictures.

Maw-seed, a name by which poppy-seed is sold as food for cage-birds when moulting.

Maxim, **SIR HIRAM STEVENS** (1840-1916), an inventive civil, mechanical, and electrical engineer, born in Maine, settled in London in 1883. He is best known as the inventor of the Maxim-gun (see **MACHINE-GUNS**), but had over one hundred patents for other inventions, the 'maximite' smokeless powder being an important one. Latterly he devoted himself to aeronautics. See *My Life* (1915), and a Life by Mottelay (1920).

Maximilian I., German emperor, the son of Frederick III., was born at Wiener-Neustadt, 22d March 1859. By his marriage with Mary, heiress of Charles the Bold, he acquired Burgundy and Flanders. But this involved him in war with Louis XI of France, and after the early death of his wife (1482) he was forced to give Artois and Burgundy to Louis. In 1486 he was elected king of the Romans. In 1490 he drove out the Hungarians, who, under Matthias Corvinus, had seized (1487) great part of the Austrian territories on the Danube; and at Villach in 1492 he routed the Turks, who had been raiding in Carinthia, Carniola, and Styria. Thereafter he set about revenging himself on Charles VIII. of France, who, on promise of papal dispensation and having rejected Maximilian's daughter, his betrothed since 1482, in 1491 married Anne of Brittany, to whom in 1490 Maximilian, with an eye to extending his dominions, had himself been wedded by procuration; but little support was given to the quarrel, and in 1493 the strife was composed in the peace of Senlis, Maximilian, however, obtaining Artois and Franche-Comté. On the death of his father in 1493 Maximilian became emperor. He subsequently married Bianca Sforza, daughter of the Duke of Milan, and turned his ambition towards Italy; but after years of war, he was compelled (1515) to give up Milan to France and Verona to the Venetians. Then in 1499 the Swiss completely separated themselves from the German empire. The hereditary dominions of his house, however, were increased by the peaceful acquisition of Tyrol; the marriage of his son Philip with the Infanta Joanna united the houses of Spain and Hapsburg; whilst the marriage in 1521 of his grandson Ferdinand with the daughter of Ladislaus of Hungary and Bohemia brought both these kingdoms to Austria. Two years after his accession the new emperor put an end to the intestine

feuds of his nobles by proclaiming at Worms the Eternal Peace. He also improved the administration of justice by establishing the Imperial Tribunal and the Imperial Aulic Council, and by admirable police regulations. The empire was divided into six (afterwards ten) circles, each ruled by a separate governor. Maximilian greatly encouraged the arts and learning, especially favoured the universities of Vienna and Ingolstadt, and caused to be written *Theuerdank* in verse and *Weisskunig* in prose, of both of which he himself is the hero, and of both of which he was probably in part author. He died at Wels, in Upper Austria, 12th January 1519. Besides being excellently schooled in mental and artistic accomplishments, Maximilian was well versed in all bodily exercises and in popular games; he had, too, a kingly presence, a chivalrous disposition, a genial manner, and has been described as the last representative of mediæval chivalry. See *Lives* by Klüpfel (1864) and 'Christopher Hare' (1913), Seton-Watson's essay (1902), Ulmann (1884-91), and a history of his reign by Hegewisch (1782).

Maximilian, **EMPEROR OF MEXICO**. Ferdinand Maximilian Joseph, Archduke of Austria, was born on 6th July 1832, and was the son of the Archduke Francis-Charles, and the younger brother of Francis-Joseph. He became an admiral of the Austrian navy, and in 1857-59 he was popular as governor of the Lombardo-Venetian territory. In 1863, at the instance of France, whose interference in Mexican affairs (at first in company with England and Spain) had ended in the military occupation of the country, he was offered the crown of Mexico by a French-nominated Mexican Assembly of Notables. After deliberation he solemnly accepted it; and in June 1864 he entered Mexico. For a time all went well; but he vainly tried to reconcile the Mexican parties. Juárez (q.v.) again raised the standard of independence; and soon after (1866) Louis Napoleon had to contemplate the withdrawal of his troops. The Empress Charlotte, a daughter of Leopold I. of Belgium, went to Europe to enlist support for her husband; but in vain, and her reason gave way with her failure. The French were most anxious that Maximilian should leave with their troops; but he felt bound as a man of honour to remain and share the fate of his followers. At the head of 8000 men he made a brave defence of Querétaro against a Liberal army under Escobedo. In May 1867 he was betrayed and tried by court-martial, and on 19th June he was shot. His death was directly due to his edict of 3d October 1865, that all Mexicans taken in arms against the empire should be shot without trial. His writings were published under the title of *Aus Meinem Leben* (7 vols. 1867). See **MEXICO**; and P. F. Martin, *Maximilian in Mexico* (1914).

Max-Müller, **FRIEDRICH**, philologist, was born at Dessau, 6th December 1823. His father, Wilhelm Müller (1794-1827), distinguished not only as a scholar, but also as one of the first German lyric poets, was librarian of the ducal library, but died prematurely. Max-Müller received the elements of his education at Dessau, and then went to Leipzig, where he studied Greek and Latin under Hermann and Haupt, and took his degree in 1843. He began the study of Sanskrit under Professor H. Brockhaus, and soon chose it as his special pursuit. The first fruits of his labours appeared in a translation of the *Hitopadesa* (Leip. 1844). In 1844 he went to Berlin to study under Bopp and Schelling, and consult the Sanskrit MSS. to be found there. In Paris, whither he repaired in 1845, he began, at the instigation of Burnouf, to prepare for an edition of the *Rig-Veda*, the 14th-

century commentary of Śāyanācārya thereupon to be included. With this view he came to England, June 1846, to examine the MSS. in the East India House and the Bodleian Library; and the East India Company commissioned him (1847) to edit the Rig-Veda at their expense (6 vols. 1849-74; new ed. 1890). In 1850 he was appointed deputy Taylorian professor of Modern Languages at Oxford; in 1854 he succeeded to the professorship; in 1858 he was elected a fellow of All Souls; and in 1866 was made professor of Comparative Philology. He published treatises on a variety of philological topics, which did more than the labours of any other single scholar to awaken in England a taste for the science of language in its modern sense. Inheriting the poetic imagination and fire of his father, Max-Müller had at command such a felicity of illustration that subjects dry under ordinary treatment became in his hands attractive. He published a translation into German of Kālidāsa's *Megha-dūta* (1847); *The Languages of the Seat of War in the East* (1854); *Comparative Mythology* (1856); *History of Sanskrit Literature* (1859); *Lectures on the Science of Language* (1861-63); *Introduction to the Science of Religion* (1873). Other works were *Chips from a German Workshop* (4 vols. 1868-75); the Hibbert Lectures on *The Origin and Growth of Religion* (1878); *Selected Essays* (1881); *Biographical Essays* (1883); *Natural, Physical, Anthropological, and Psychical Religion* (Glasgow Gifford Lectures, 1888-92; published 1889-93); and *Science of Mythology* (2 vols. 1897). A novel written in German, *Deutsche Liebe* (1857), went through many editions. He edited the important series of *The Sacred Books of the East*. He died at Oxford, 28th October 1900. *Auld Lang Syne* (1898-99) and *My Autobiography* (1901) are autobiographical fragments; his widow edited his *Life and Letters* (2 vols. 1902).

Maxwell, JAMES CLERK, one of the greatest of modern natural philosophers, was born at Edinburgh 13th June 1831. He was educated in boyhood at the Edinburgh Academy. Before he was fifteen his first published scientific paper was read for him by Professor Forbes to the Royal Society of Edinburgh. He spent three years at the university of Edinburgh, and during this period he wrote two valuable papers, 'On the Theory of Rolling Curves,' and 'On the Equilibrium of Elastic Solids.' He went to Cambridge in 1850, in 1854 was second wrangler, and was declared equal with the senior wrangler in the higher ordeal of the Smith's prize. In 1856 he became professor of Natural Philosophy in Marischal College, Aberdeen, and in 1860 of Physics and Astronomy in King's College, London. He had been successively scholar and fellow of Trinity, and was elected an honorary fellow of Trinity when he finally became in 1871 first professor of Experimental Physics in the university of Cambridge. He died 5th November 1879.

The great work of his life is his treatise on *Electricity and Magnetism* (2 vols. 1873). His great object was to construct a theory of electricity in which 'action at a distance' should have no place; and his success was wonderful. For his electro-magnetic theory of light, see the latter part of the article **ELECTRICITY**, the last paragraph of **MAGNETISM**, and the articles **LIGHT** and **REFRACTION**; and for its practical application, **WIRELESS TELEGRAPHY**, **WIRELESS TELEPHONY**. Another subject to which he devoted much attention was the perception of colour and the cause of colour-blindness. He was the first to make colour-sensation the subject of actual measurement. He obtained the Adams prize for his splendid discussion of the dynamical conditions of stability of the ring-system of Saturn. But he was perhaps best

known to the public by his investigations on the kinetic theory of gases. His Bradford 'Discourse on Molecules' is a classic in science. Besides a great number of papers on various subjects, mathematical, optical, dynamical, he published an extraordinary text-book of the *Theory of Heat* and an exceedingly suggestive little treatise on *Matter and Motion*. In 1879 he edited, with copious and very valuable original notes, *The Electrical Researches of the Hon. Henry Cavendish*. He took a prominent part in the construction of the British Association Unit of Electrical Resistance, and in writing the Association's admirable reports on the subject; and he discovered that viscous fluids, while yielding to stress, possess double refraction. He was excessively ingenious in illustration, especially by means of diagrams, and possessed a singular power of epigrammatic versification. Some of his last and very best scientific work adorns and enriches the ninth edition of the *Encyclopædia Britannica*. His *Scientific Papers* were edited by W. D. Niven (2 vols. Camb. 1890); and his *Life* was written by Lewis Campbell and William Garnett (1882).

Maxwell, MRS JOHN. See BRADDON.

Maxwell, SIR WILLIAM STIRLING- (1818-78), was born at Kenmure House, near Glasgow. Graduating from Trinity College, Cambridge, he travelled in Italy and Spain, and wrote *Annals of the Artists of Spain* (3 vols. 1848), a sumptuous *Don John of Austria* (1883), and works on the Emperor Charles V., on Vesalius (privately issued), and on Velázquez (1885). Having succeeded (1866) to the baronetcy and estates of his uncle, Sir John Maxwell of Pollok, he added the name of Maxwell to his own. His second wife (1877) was the Hon. Mrs Norton (q.v.). He sat in parliament as a Conservative (1852-68, 1874-78). A new edition of his Works was published in 6 vols. in 1891.

May (Lat. *Maius*), the fifth month (31 days) of the year in the Julian and Gregorian calendar, the third in the old Roman. The etymology of the word is uncertain, but is usually connected with the name of the goddess Maia, the mother of Mercury, and a deity of growth and of increase. From primitive times the revival of vegetation, which in certain countries marks Nature at this period, has been celebrated with various ceremonies. Thus the first of May has from time immemorial been a gala day in Britain, although, like most of the festivals of the calendar, it has suffered from the hand of time. It is no doubt a survival of the Floralia of the Romans, who in their turn, it has been suggested, derived their festival from India. The anniversary is still kept up by the Italians under the title of 'Calendi di Maggio,' young people sallying forth at daybreak to collect boughs to decorate the house-doors of their relatives and friends. A remnant of the May festival survives in *Beltane* (q.v.). In England, as we learn from Chaucer and Shakespeare and other writers, it was customary during the middle ages for all, both high and low—even the court itself—to go out on the first May morning at an early hour 'to fetch the flowers fresh.' Hawthorn (q.v.) branches were also gathered; these were brought home about sunrise, with accompaniments of horn and tabor and all possible signs of joy and merriment. The people then proceeded to decorate the doors and windows of their houses with the spoils. By a natural transition of ideas they gave the hawthorn bloom the name of the 'May'; they called the ceremony 'bringing home the May'; they spoke of the expedition to the woods as 'going a-Maying.' The fairest maid of the village was crowned with flowers as the 'Queen of the May,' and placed in a little bower or arbour, where she sat in state receiving the homage and admiration

of the youthful revellers who danced and sang around her. Another conspicuous feature of these festive proceedings was the erection in every town and village of a fixed pole—called the Maypole—as high as the mast of a vessel, on which each May morning were suspended wreaths of flowers, and round which the people danced in rings pretty nearly the whole day. The earliest representation of an English Maypole is that on a window of the time of Henry VIII. or earlier, at Betley, in Staffordshire; it is reproduced in the *Variorum Shakespeare*. A severe blow was given to these merry customs by the Puritans, who caused Maypoles to be uprooted, and a stop put to all their jollities. They were, however, revived after the Restoration, and held their ground for a long time; but they have now almost disappeared. In France and Germany, too, Maypoles were common, and in some places are still to be seen, and festive sports are even yet observed. See Chambers's *Book of Days*. With Catholics, since 1815, the month of May has been specially celebrated as the Virgin's month; and in Scotland, from some time at least before Mary's marriage to Bothwell (1567), as long before with the Romans, it has been deemed an unlucky month to marry in. International demonstrations of workmen in favour of a compulsory eight hours' working day took place in Europe and America on 1st May 1890, and since then the first of May has come to be generally recognised as a labour day, on which labour and socialist demonstrations are held.

May, ISLE OF, an islet of Fife at the mouth of the Firth of Forth. It has a lighthouse, a ruined 13th-century priory, and traces of holy wells of the time when the island was a favourite place of pilgrimage.

May, PHIL (1864–1903), caricaturist, was born at Wortley, near Leeds. Orphaned at nine, he had been foundry time-keeper, colour-grinder for a scene-painter, drawer of shilling portraits of actors, actor, &c., before coming, when about seventeen, to London, where he suffered extreme want until finding employment as a designer to a theatrical costumier, and work on the *St Stephen's Review* as poster artist and cartoonist. In 1884 he went to Australia, where he worked on the *Sydney Bulletin*, but in 1892 returned to London to establish his reputation with his *Annual* and his contributions to *Punch*—in 1896 he became a member of the permanent staff—the *Graphic*, &c. He excelled in depicting East London types, and an extraordinary economy of line was a characteristic feature of his work.

May, THOMAS (1595–1650), dramatist and historiographer, was educated at Cambridge, and became a member of Gray's Inn and a courtier. He produced several dramas (*Antigone*, *Cleopatra*, *Agrippina*, &c.) and comedies, poems, and translations of the Georgics and of Lucan's *Pharsalia*. During the Civil War he was made secretary and historiographer to the Parliament, and produced a *History of the Parliament of England, 1640–1643* (1647; several times republished), and a *Breviary* of the same history (1650).

May, SIR THOMAS ERSKINE, Baron Farnborough, born in 1815, was educated at Bedford School, became assistant librarian of the House of Commons in 1831, clerk-assistant in 1856, and clerk of the House in 1871. He was called to the bar in 1838, was made in 1860 Companion, in 1866 Knight Commander, of the Bath, and shortly after his retirement from office in 1886 was raised to the peerage as Baron Farnborough, but died on 18th May of that year. His most important works are *A Treatise on the Law, Privileges, Proceedings, and Usage of Parliament* (1844), which, acknowledged

as the parliamentary text-book, had gone through six editions before his death; *Constitutional History of England since the Accession of George III., 1760–1860* (1861–63; ed. F. Holland, 1912), a continuation of Hallam; and *Democracy in Europe: a History* (2 vols. 1877), a work characterised by great learning and impartiality.

Mayas, an American Indian people inhabiting Yucatán (q.v.), Chiapas, and other Mexican states, as well as parts of Guatemala, Honduras, and British Honduras. The ruins of Uxmal, Chichen, Mayapan, and other cities in Mexico, and especially Copán (q.v.) in Honduras, richly carved temples and other vast edifices, testify to their high civilisation in ancient times (from perhaps the 1st century B.C. onwards), as do also their underground reservoirs for water in an ill-watered land, their hieroglyphic writing, distinct from that of the Aztecs, and the astronomical lore illustrated by their calendar. See books by Maudslay (1889–1902), Joyce (1916), Gann (1918), and Morley (1920).

Maybole, a town of Ayrshire, $3\frac{1}{2}$ miles inland, and 9 by rail S. by W. of Ayr. In feudal times the capital of Carrick, and a burgh of barony since 1516, it is an old-world place, which once boasted twenty-eight baronial mansions, several of which still remain; besides these, it has a town-hall and a fine Roman Catholic church. Shoemaking is the staple industry. The famous abbey of Crossraguel (q.v.) is in the vicinity. Pop. 4400.

Mayence. See MAINZ.

Mayenne (Lat. *Meduana*), a French department formed out of the old provinces of Maine and Anjou, now containing the arrondissements of Laval, Château-Gontier, and Mayenne, has an area of 1996 sq. m. and a pop. of (1872) 350,637; (1921) 262,447. The valleys of the Mayenne, Vilaine, and Sarthe are fairly fertile, and yield wheat, barley, flax, potatoes, hemp, and fruit (especially apples for cider). Cattle-breeding, coal and slate mining, and cotton spinning and weaving are the other chief industries. Chief town, Laval.—The river Mayenne, after a course of 127 miles in a southerly direction, joins the Sarthe at Angers to form the Maine, a tributary of the Loire. It is navigable up to Laval.—The town of Mayenne, on the river Mayenne, 78 miles by rail S. by W. of Caen, has a picturesque ruined castle (taken by the English in 1424), steep narrow streets, and manufactures of calico and linen. Pop. 10,000.

Mayer, JULIUS ROBERT VON, physicist, was born at Heilbronn, 25th November 1814, studied medicine at Tübingen, Munich, and Paris, began life as a ship's surgeon, and settled in his native town to practise his profession in 1841. Whilst at Batavia in 1840 his attention was first attracted to the studies he afterwards pursued in every interval of leisure. In 1842 he published in Liebig's *Annalen* a preliminary statement of the mechanical theory of heat, in which he clearly determined the numerical relation between heat and work. Three years later he restated his views with admirable clearness and with a great wealth of illustration, and at the same time gave a forecast of his theory of the meteoric origin of the sun's heat, elaborated in 1848. Contemporaneously with Mayer the mechanical theory of heat was worked out independently by Joule (q.v.) in England. Nevertheless a controversy arose as to the priority of discovery. The Royal Society gave him the Copley medal in 1871, and he was ennobled by Württemberg two years before his death, on 20th March 1878.

See his papers collected as *Mechanik der Wärme* (3d ed. 1893), and his letters (1889); also Gross, *Robert Meyer und Hermann von Helmholtz* (1898); and monographs in German by Dühring (1879), Weyrauch (1890), and Friedländer (1905).

Mayfair, the unofficial designation of a fashionable residential district of the West End of London (q.v.) between Bond Street and Park Lane, named from a somewhat riotous fair held there in May as early as the time of Charles II., but suppressed at the end of the 18th century.

Mayflower, May-fly, May Laws. See PILGRIM FATHERS, EPHEMERA, FALK.

Mayhem. See ASSAULT.

Mayhew, AUGUSTUS (1826-75), wrote in conjunction with his brother Henry several notable works of humorous fiction, the best of which are named in the article below. In addition to this, the better-known part of his work, he wrote several stories popular at the time—*Paved with Gold* (1857), *The Finest Girl in Bloomsbury* (1861), *Faces for Fortunes* (1865), &c.

Mayhew, HENRY, born in London in November 1812, ran away from Westminster School under a sense of unjust treatment, was sent on a voyage to Calcutta, and on returning was articled to his father, a solicitor. Mayhew's first adventure in literature was the starting, in conjunction with Gilbert à Beckett, of *The Cerberus*, the production of which was stopped by à Beckett's father. The two youths in disguise left their homes, and with but fifteen shillings between them walked to Edinburgh, hoping to make fortunes there as actors and authors at the theatre of which Mayhew's brother Edward was lessee; this failed, for they were at once sent back. In 1831 they started *Figaro in London*, and the year following *The Thief*, which was the prototype of the 'Bits' journals of to-day. In 1841 Mayhew produced *The Wandering Minstrel*, a farce, and shortly after joined with his brother Augustus in one of the most successful of literary partnerships, during which (as 'the Brothers Mayhew') they produced some remarkably clever works of fiction, the best of which are *The Good Genius that turned Everything to Gold* (1847), *The Greatest Plague of Life* (1847), *The Image of His Father* (1848), *Whom to Marry* (1848), *The Magic of Kindness* (1849), *Living for Appearances* (1855). One of the originators and first editor (jointly with Mark Lemon) of *Punch*, Mayhew was from early in the forties a voluminous writer on many subjects—as on *The Peasant Boy Philosopher* (1854), *The Wonders of Science* (1855), *Shops and Companies of London* (1865), *London Characters* (1874), and the *Criminal Prisons of London*. The work by which he will perhaps be best remembered is his *London Labour and the London Poor* (1851, &c.). Mayhew, who had married in 1844 the elder daughter of Douglas Jerrold, died 25th July 1887.

Mayhew, HORACE (1816-72), brother of the two foregoing, also made some mark in literature, more especially of a humorous and ephemeral kind. He was a constant contributor to *Punch*, of which he was at one time sub-editor.

Maynooth, a village of County Kildare, Ireland, 15 miles NW. of Dublin, is of historical interest as the seat of the Geraldines of whose castle striking ruins still remain, and as the scene of more than one struggle with the English power, especially in the reign of Henry VIII. (the 'Rebellion of Silken Thomas'), and in the war of the Confederates (1641-50). But its chief modern interest arises from its Roman Catholic college, established (1795) by an act of the Irish parliament to meet a necessity created by the destruction, through the French Revolution, of the places of education in France upon which the Irish Catholic clergy, excluded by the penal laws from the opportunity of domestic education, had been driven to rely. Politically its foundation was principally due to the work of Burke and of Grattan. The annual vote

was continued, not without opposition, by the imperial parliament after the Union. In 1845 Peel carried a bill for an increased endowment. The building erected under the original endowment is a plain quadrangle. The new college is a very striking Gothic quadrangle by Pugin, containing professors' and students' apartments, lecture-halls, and a singularly fine library and refectory.

Under the Act of 1845 the college was to receive 500 students, all destined for the priesthood. The patronage of the 500 studentships was divided in the ratio of population among the bishops of the several sees of Ireland.

In 1869, by the Irish Church Act, the Maynooth endowment was withdrawn—a capital sum, fourteen times its amount, being granted to the trustees for the discharge of existing interests. The college was maintained on the same footing, the visitatorial powers created under the act of parliament being exercised by visitors appointed by the trustees. In 1909 Maynooth became an affiliated college of the National University, almost on the footing of a constituent college, but it is not represented on the senate. The college possesses some landed and funded property, the result of donations and bequests. The chapel, originally included in the design supplied for the college by Pugin in 1846, was (with the exception of a tower and spire 275 feet high) completed in 1890. Designed by J. J. McCarthy in the Decorated Gothic style, it consists of a great nave, choir, and sanctuary, ending in a five-sided apse, from which radiate five chapels. The entire length is 220 feet, the width 40 feet, the height from floor to groined ceiling 70 feet. The sides of the chapel are flanked by cloisters which exteriorly present the appearance of aisles. The interior is richly fitted with choir-stalls of finely-carved oak, mosaic pavements of varied devices, altars of Carrara marble, rich painted glass, and a sweetly-toned organ. A great part of the college was burned in 1878, but was soon restored.

See *Maynooth: a Centenary History*, by the Most Rev. Father Healy (1895).

Mayo, a maritime county of the province of Connaught, Irish Free State, is bounded on the N. and W. by the Atlantic Ocean, E. by Sligo and Roscommon, and S. by Galway. The greatest length north and south is 68 miles, the greatest breadth, 57 miles. Area, 2157 sq. m., of which a large percentage is bog or barren, though there are some very fertile regions; of the agricultural land only a relatively small proportion is under tillage, the remainder being in pasture. Pop. (1841) 388,887; (1861) 254,769; (1881) 245,212; (1901) 199,166; (1911) 192,177, almost all Roman Catholics. Agriculture is the leading industry; cattle, sheep, pigs, and poultry are raised, and oats and potatoes are the principal crops. There is also some manufacture of coarse woollen and linen cloths. The eastern half of the county is more or less a plain, the western half mountainous, the highest points being Mulrea (2688 feet), Nephin (2530), and Croagh Patrick (2370). Ironstone abounds, but owing to want of fuel is not worked; and there are several valuable slate-quarries. The chief towns are Castlebar (3700), the county town; Westport (3700); Ballina (4700), formerly partly in County Sligo; and Ballinrobe (1600). The coastline of Mayo is about 250 miles, and is greatly indented, Killala, Blacksod, and Clew Bays, Killary Harbour, and Broad Haven being on this coast, which abounds in picturesque scenery. Off Mayo, too, lie the islands Achill, the largest island off Ireland, Clare, and many others. Loughs Mask and Corrib lie on the southern border, and Loughs Conn, Castlebar, Cullen, Carragh, Corramore within the county. A valuable salmon-fishery exists in the river Moy, and Lough Mask is the home of the

'gillaroo' trout. The Irish language was in 1911 spoken by 1500 persons who did not know English, and by 87,000 who did. Nine members are returned to Dáil Eireann, four for North, five for South Mayo.

Mayo formed part of the extensive territory granted by King John to Hubert de Burgh; but William, the third earl, seizing Galway and Mayo, threw off the English allegiance and adopted the 'customs of the Irish,' together with the Celtic name of Mac-William. The district was not subdued until 1586. The antiquities of Mayo are chiefly ecclesiastical, there being many ruins of monasteries. There are round towers at Killala, Turlough, Meelick, and Balla, an imperfect one at Aughagower, and at Cong the remains of a splendid 12th-century abbey. The celebrated 'Cross of Cong,' now in the Royal Irish Academy's museum, was made at Roscommon in 1120.

Mayo, RICHARD SOUTHWELL BOURKE, EARL OF, Indian statesman, was born in Dublin on 21st February 1822, and educated at Trinity College, Dublin. He entered the House of Commons as a Conservative in 1847, and was appointed Chief-secretary of Ireland in 1852, 1858, and 1866. In 1869 he succeeded Lord Lawrence as Viceroy of India. His administration was notable. He maintained friendly relations with the neighbouring states, treated the feudatory princes and the native people with impartial but temperate justice, put the finances of the country on a sound basis, and effected improvements in gaol discipline, in irrigation works, and in providing educational facilities for the native Mohammedan population. Whilst inspecting the penal settlement at Port Blair on the Andaman Islands, on 8th February 1872, he was fatally stabbed by a convict. See a Life by Sir W. W. Hunter (2 vols. 1875).

Mayonnaise, a thick cold sauce for salads, cold meat, poultry, fish, vegetables, &c., made of the yolk of eggs, salad-oil, and vinegar, with a little salt, cayenne pepper, and meat-jelly; it is sometimes coloured red with powdered lobster coral, or green with spinach or parsley. The etymology of the term is uncertain, and *Bayonnaise* (from Bayonne, the alleged place of invention) and *Mahonnaise* (from Port Malou, Minorca, captured in 1756 by the Duke of Richelieu, 1696-1788, grand-nephew of the cardinal, and the alleged inventor) are both claimed as the correct forms of the word.

Mayor (Fr. *maire*, Lat. *major*; see MAJOR), originally a steward, bailiff, or overseer, thence the chief-magistrate of a city or corporate town in England or Ireland. The mayor is the head of the local judicature, and the executive officer of the municipality; he is elected by the council from the aldermen or councillors, and holds office for a year only. His duties include those of returning officer in all boroughs except those cities and towns which, being counties of themselves, have sheriffs of their own. The first Mayor of London was appointed in 1189, the first Mayor of Dublin in 1409. The mayors of London, York, and Dublin, and now also of Liverpool, Manchester, Leeds, Sheffield, Birmingham, Bristol, Cardiff, Bradford, Newcastle, Belfast, Cork, Norwich, and Hull are called 'Lord Mayor.' The Lord Mayor of London (q.v.)—since 1354 'Right Honourable'—is the representative of royalty in the civil government of the city, is in the position of the lord-lieutenant of a county, and on the demise of a sovereign is summoned to attend the Privy-council. To sustain the hospitality of the city he receives an allowance of £10,000 a year, with the use of the Mansion House (q.v.), furniture, carriages, &c. He is chosen annually by the aldermen from two aldermen nominated by the Common Hall (see LONDON),

being commonly the senior alderman who has not already 'passed the chair.' Although the office is still one of dignity, it is only in the eyes of foreigners that the Lord Mayor of London is one of the most important public functionaries of the realm. The Mayor of Dublin was first styled Lord Mayor by Charles II. in 1665. The title of Mayor is used to denote the chief officer of a city in the United States and the British colonies. In France the Maire is first officer of a town, commune, or district. For the corresponding office in Scotland see PROVOST; and for the Mayor of the Palace, see PEPIN.

Mayotte, one of the Comoro Isles (q.v.).

Maysville, capital of Mason county, Kentucky, on the Ohio River, 69 miles by rail N.E. of Lexington. It is the river-port of a rich territory, and manufactures tobacco, flour, ploughs, cotton, shoes, &c. Pop. 6000.

Mayweed, or STINKING CAMOMILE. See CAMOMILE.

Mazamet, a town in the French department of Tarn, on the Arnette, 43 miles ESE. of Toulouse, has extensive woollen manufactures; pop. 14,000.

Mazanderan, a province of northern Persia, fringing the Caspian Sea for some 200 miles and lying between the provinces of Ghilan and Astrabad, consists of a belt of low marshy coast-land, 10 to 20 miles wide, backed by the well-wooded northern slopes of the Elburz. The climate is very changeable, in summer both rainy and unhealthy, but on the uplands fairly salubrious. Owing to the fertility of the soil, which is watered by numerous small rivers, the Persians call the province the 'Garden of Iran.' Rice, wheat, and other cereals, cotton, mulberry-trees, and a variety of fruits are produced. Horses, asses, and camels are extensively bred. Area, 10,400 sq. m.; pop. estimated at from 150,000 to 300,000. The capital is Sari, though Barfurush (see BALFURUSH) is the seat of the trade with Russia. Iron ores and mineral oils are very abundant.

Mazara del Vallo, a walled cathedral city of Sicily, 25 miles S. of Trapani, in a fertile plain on the seashore. It exports grain, olive-oil, fruit, &c. Pop. 22,000.

Mazarin, JULES (*Giulio Mazarini*), cardinal and chief-minister of France during the minority of Louis XIV., was born 14th July 1602 at Piscina in the Abruzzi. He studied under the Jesuits at Rome, and later at Alcalá in Spain, where he relieved the tedium of study with love-making. He next entered the military service of the pope, but his ability for diplomacy was early recognised. Having accompanied a papal legate to the court of France, he became known about 1628 to Richelieu, who divined his promise and engaged him to maintain French interests in Italy, which he did while still employed by the pope as vice-legate to Avignon (1632) and nuncio to the French court (1634-36). In 1639 he openly entered the service of Louis XIII. and was naturalised a Frenchman; and two years later he received a cardinal's hat through the influence of Richelieu, who before his death (4th December 1642) recommended Mazarin to the king as his successor. His position was one of great difficulty amid the intrigues and jealousies of the time, and the first necessity was that he should make himself indispensable to the queen, who became regent on her husband's death in May 1643. But Mazarin was one of the most supple courtiers that ever bowed the knee before a throne, and moreover he knew how to touch a woman's heart by his romantic devotion. So he kept his place as minister, and it is certain, from his famous *carnets* and many of

the Brühl letters, that the queen gave him her love, if it cannot with certainty be proved that there was a private marriage between them; that this was perfectly possible has been shown by the historian Chéruel, who discovered that the cardinal had never taken more than the minor orders, of which a man could easily divest himself. Mazarin possessed admirable faculty for affairs and so much personal charm that he ruled with greater smoothness than Richelieu, although with almost as unlimited a sway. The parlement of Paris seeing itself threatened in its political rights embarked on a course of determined opposition; but Mazarin caused the leaders of the opposition to be arrested (August 1648), upon which the disturbances of the Fronde (q.v.) began. The court retired to St Germain, but at length triumphed by the aid of Condé, and the truce of Ruel, while it removed the obnoxious taxes, left Mazarin and his subordinates in office. The hatred against him, however, blazed out anew in the provinces, when at his instigation the queen-regent arrested Condé, Conti, and Longueville in January 1650. Mazarin triumphed at Réthel, but soon had to succumb to the strength of the combination against him and retire to exile at Brühl. Meantime the press teemed with pamphlets and satires against him—the famous *Mazarinades*, few of which, however, attained the dignity of literature. The cardinal now perceived the fatal consequences of his policy of isolating himself and the queen from every party in the state, and bent all his masterly powers of intrigue to form a new royal party. Turenne was gained over, and his military genius proved more than adequate as a counterpoise to the opposition of Condé. After one year's absence Mazarin returned to court in January 1652, but eight months later again retired to Sedan to admit of a reconciliation with the *parlement* of Paris. At length in February 1653 he returned in triumph to Paris, and thereafter his power remained secure, while he quickly regained all his popularity. Under his rule the influence of France abroad was greatly increased. He gained the alliance of Cromwell at the price of Dunkirk; secured the preponderance of French influence in southern Germany by the treaty of Westphalia (1648), and the league of the Rhine, formed in 1659; and by the treaty of the Pyrenees (November 7, 1659), and the marriage of Louis XIV. with the Infanta Maria Theresa, brought the succession to the throne of Spain within the range of French ambition. Mazarin died at Vincennes, 9th March 1661, leaving an immense fortune, variously stated at from 18 to 40 million livres. His magnificent library, which had long been placed freely at the disposal of the public, was bequeathed to the Collège Mazarin. His name survives characteristically in the 'Mazarin Bible,' one of the most priceless treasures of Bibliomania (q.v.).

His celebrated nieces whom he brought from Italy to the French court present all the possible contrasts of character and destiny. The eldest of the seven, the virtuous Laura Mancini, married the Duc de Mercœur, son of Henry IV. and Gabrielle, and died young. Anne-Marie Martinozzi, her cousin, married the Prince de Conti, an austere and gloomy hunchback, and also died young. Laura Martinozzi mounted a throne by marrying the Duke of Modena, and became mother of the second wife of James II. of England. Olympe Mancini, who became Comtesse de Soissons, was a woman formed for great crimes, whose true place would have been in the palace of the Cæsars or the Vatican of the Borgias. She plunged deep into a series of discreditable intrigues, and found herself obliged to flee from France to escape the punishment of a poisoner. After fitting awhile

like an evil genius over the face of Europe, she died poor and obscure at Brussels. Hortense Mancini, the most beautiful of the seven, and her uncle's favourite, inherited his fortune, and was sought in marriage by the Duke of Savoy, the Prince of Portugal, and the King of England. The cardinal married her to the Duc de la Meilleraie, who took the name and arms of Mazarin. He was a gloomy bigot, who mutilated with the fury of a Byzantine iconoclast the magnificent antique statues which Mazarin had collected with all an Italian's love for art, shut up his wife, and treated her with a jealous severity which afforded in the morality of the time ample justification for her misconduct. She found at once a refuge from his pursuit in England, and a characteristic recreation in an intrigue with Charles II. Marie-Anne Mancini became Duchesse de Bouillon, and was the generous patroness of Lafontaine and other men of letters. Her reputation was not spotless, but her wit brought her off triumphant from an examination for sorcery before the *Chambre Ardente* which her sister could not face. Marie Mancini, the least beautiful of the seven, was beloved by Louis XIV., who would have married her but for the self-denying opposition of his great minister. She found shelter but not consolation in the arms of Prince Colonna, one of the jealous husbands of old Italian story. She fled from his severity to Provence, to Flanders, and to Spain, but was at length secured and subdued.

See the *Mémoires* of such contemporaries as De Retz, Madame Motteville, La Rochefoucauld, Turenne, Grammont, and Bazin's *Hist. de France sous Louis XIII. et sous le Card. Mazarin* (4 vols. 1846); but especially Chéruel's *Hist. de France pendant la Minorité de Louis XIV.* (4 vols. 1879-80), his *Hist. de France sous le Ministère de Mazarin* (3 vols. 1881-82), and his edition of the *Lettres* (6 vols. 1879-91); also Moreau's *Bibliographie des Mazarinades* (1850-51), and the *Choix de Mazarinades* (1853); Cousin's *Jeunesse de Mazarin* (1865), Rencée's *Les Nieces de Mazarin* (1856), Masson's *Mazarin* (1886), Hassall's *Mazarin* (1903), and Noel Williams's *Five Fair Sisters* (1906).

Mazarrón, or ALMAZARRÓN, a town of Spain in a lead and iron mining district of Murcia, 18 miles W. of Cartagena, and joined by rail (3 miles) to its port (Porta Azoia) on the Mediterranean. There are metallurgical works, and soap and flour mills. Pop. 18,000.

Mazas, a famous prison in Paris, built in 1845-50 (to replace that of *La Force*), but demolished in 1900, in which was made the first trial of solitary confinement in France. It stood on the Boulevard Mazas (now Boulevard Diderot).

Mazatlán, a fortified seaport of Mexico, on the Mazatlán, at the mouth of the Gulf of California. It has a nautical school, and a meteorological and a wireless station. There are saw-mills and foundries, and manufactures of cotton, rope, &c. Its trade, both import and export, is important, and among exports are hides, gold and silver, archil, and mother-of-pearl. Pop. 25,000.

Maze. See LABYRINTH.

Mazeppa, IVAN STEPANOVICH, hetman of the Cossacks, was born in 1644, descended of a poor but noble family of Podolia. He became a page at the court of John Casimir, king of Poland. A Polish nobleman, having surprised him in an intrigue with his wife, caused him to be stripped naked, and bound upon his own horse, which, let loose, carried him, senseless from exhaustion, to its native wilds of the Ukraine. A more credible story is that his horse bore him back, torn and bleeding, to his own home. Mazeppa now joined the Cossacks, became secretary to their hetman, Samoilovich, and in 1687 was elected his successor. He won the confidence of Peter the Great, who loaded him with honours and made him Prince

of the Ukraine; but, on the curtailment of the freedom of the Cossacks by Russia, Mazeppa conceived the idea of throwing off the sovereignty of the tsar, and for this purpose entered into negotiations with Charles XII. of Sweden. His treason was revealed to Peter the Great, who long refused to credit it, but after Pultowa (q.v.) ordered his effigy to be hanged upon the gallows, and his capital, Baturin, to be razed to the ground. Mazeppa's hopes perished in 1709 in the disaster of Pultowa, and he fled with Charles to Bender, where he died miserably the same year. His story is the subject of poems, novels, plays, opera, symphonic poem, and paintings, by Byron, Bulgarin, Gottschall, Tchaikowsky, Liszt, Vernet, &c., and of a masterly history by Kostomarov (1882).

Mazurka, a lively Polish round dance, the music of which is generally in $\frac{3}{4}$ time. The peculiarity of the rhythm, which has a pleasing effect, is what characterises the music of the Mazurka. It is danced by four or eight couples.

Mazzarino, a town of Sicily, 15 miles SE. of Caltanissetta. Its trade is agricultural. Pop. 20,000.

Mazzini, GIUSEPPE, was born at Genoa, 22d June 1805. A clever, precocious boy, he began to study at the university of his native town when only thirteen, and before he was nineteen was practising as an advocate. In April 1821 his heart was deeply stirred through seeing refugees from the unsuccessful rising in Piedmont (see ITALY), and from that moment he conceived the idea of the liberation of his country. At first he assailed the domination of the classical school of literature, and its 'monarchical' tyranny of rule and prescription. But the earnestness of his nature soon pushed him on to make 'the first great sacrifice of his life,' by renouncing 'the career of literature for the more direct path of political action.' In 1829 he joined the Carbonari (q.v.), although he mistrusted their aims, their methods, and the character of their organisation. He was betrayed in July 1830 to the Sardinian police, and imprisoned in Savona. In his prison cell he matured those thoughts which became the ruling principles of his life and work, and shortly after his release, early in the following year, organised at Marseilles the Young Italy Association. The first and last duty of its members was to labour to create a free, independent, and united nation of Italians. The great mass of the people were to be educated to understand their rights, and taught to obtain them, if need were, through insurrection. But Italy must first be freed from the yoke of the foreigner. Nothing but a republic could serve her political needs in the future. Once Italy were regenerated, she 'was destined to arise the initiatrix of a new life, and of a new and powerful unity to all the nations of Europe'—the selfsame rôle that Heine and Young Germany assigned to regenerated Germany. The ultimate goal was the governance of the world by the moral law of progress, through the effective agencies of association, man with man and nation with nation. 'The labour to be undertaken was not merely political, but above all a moral work; not negative, but religious.' It was essentially the practice of a faith, the living of a creed, a religion. It was in this spirit that Mazzini laboured to his life's end—unwaveringly, disinterestedly, through the bitterest humiliations of exile, and at the cost of the greatest personal sacrifices.

Shortly after Charles Albert ascended the throne of Piedmont (April 1831) Mazzini addressed to him a manly appeal, urging him to put himself at the head of the struggle for Italian independence, and to grant needful concessions to his people's cry for liberty. His answer was a sentence of perpetual banishment, Metternich having forced the new

king to take a commission in the dragoonades of reaction. Further, in August 1832 the French authorities expelled him from the country. But he outwitted them, and hid awhile at Marseilles. From this time he led for more than twenty years 'a life of voluntary imprisonment within the four walls of a little room.' But no confinement could quell his spirit or restrain his activity. Henceforward he was the most untiring political agitator in Europe, the man most dreaded by its absolute governments; with Lassalle he was one of the most conspicuously successful of the century. He wrote incessantly, in a strain of such fervid eloquence, and with such an intensity of conviction, that his words kindled in the hearts of those that read them the enthusiasm to do and dare all things. Though by nature frank, open, and bold, no man perhaps learned to understand better the tortuous arts of secret conspiracy. He was driven to adopt this underground method of warfare by the power and vigilance and unscrupulous character of the enemies he contended against, and the close and united front they presented to every revolutionary assault. In 1834 he organised an invasion of Savoy, which failed ignominiously, chiefly through the lukewarmness, if not treachery, of the soldier placed at its head. The next two years Mazzini spent in Switzerland, incessantly active, extending his organisation throughout Italy, instigating his countrymen to insurrection, and scattering broadcast through Europe the bursting seeds of republican revolt. In the year of the Savoy fiasco he drew up, at Bern, for Young Europe—i.e. Young Italy, Young Germany, and Young Poland united—the *Pact of Fraternity*, a code of abstract doctrines dictating to humanity a faith and rules of life. Being in the last days of 1836 banished from Switzerland, he found a refuge in London. Although for some years (1841-48) he struggled hard against poverty, he nevertheless contrived to help his poorer, ignorant countrymen, the organ-boys of London, by gathering them round him in night-classes and teaching them and civilising them. In 1844 he charged the English government with opening his letters, and communicating their contents to the rulers in Italy, and made good his accusation. This raised a great storm of indignation throughout the country, and drew from Carlyle a spirited testimonial to Mazzini in *The Times*. Sir James Graham, the Home Secretary, even felt constrained to apologise in the House of Commons for having publicly repeated the calumnies of his enemies.

On the outbreak of the Lombard revolt in 1848 Mazzini hastened to throw himself into the thick of the struggle. The king of Sardinia sought to win him over by the promise to make him first minister in the new Piedmontese-Lombard state, and to grant him as large a share as he might desire in the framing of a constitution for it. But Mazzini's aims were not of personal ambition, and he would be no party to the aggrandisement of the dynasty of Savoy at the expense, or to the detriment, of a united Italy. After Milan capitulated, he tried with Garibaldi to keep the war alive in the valleys of the Alps; but, when he saw that all was over in Lombardy, he made his way to Tuscany. Leghorn received him with wild enthusiasm on 8th February 1849, the day before the republic was proclaimed at Rome, and elected him her deputy to the republican assembly in the papal city. On 29th March Mazzini, Saffi, and Armellini were appointed a triumvirate with dictatorial powers; they chose as their motto 'God and the People.' But on 25th April the French arrived before the city to reinstate the pope, and after a tough struggle were admitted within the walls. The republic fell, and the triumvirs indignantly resigned on the last day of June.

Mazzini made his way back to London. Not however to rest: he planned the attempted risings at Mantua (1852), Milan (1853), Genoa (1857), and Leghorn (1857). Meanwhile in London he had founded, along with Kossuth and Ledru-Rollin, the European Association, and with them issued in September 1855 its republican manifesto. The Society of the Friends of Italy was organised about this time in England. In 1859 Mazzini condemned the alliance Piedmont had made with Napoleon III.; and the cession of Savoy and Nice to France not only justified his prophetic warning, but filled him (and Garibaldi) with the patriot's sorrowful indignation. He supported Garibaldi in his expedition against Sicily and Naples with all his influence and all his resources; and when Piedmont stepped in to reap the fruits of the soldier's heroic exertions, and even scattered his followers and took him prisoner at Aspromonte (1862), Mazzini broke finally with the monarchical party. The king replied to his fulminant by again passing sentence of death upon him—the third time. But this did not deter him from stigmatising the Convention of September (see ITALY) as a base compromise. In 1866–67 Messina in protest elected him its deputy to the Italian parliament four times in succession. Two years later he was again expelled from Switzerland, and in the following year (1870) was arrested at sea, whilst on his way to Sicily, and carried prisoner to Gaeta. After being detained two months he was set at liberty. He settled at Lugano, but died at Pisa, 10th March 1872, and was buried in his native city, mourned by the entire nation he had done so much to create.

Although from one point of view a utopian idealist and political dreamer, the apostle of the new democratic evangel, and from another point of view a restless demagogue, a dark conspirator, and disturber of the peace of Europe, Mazzini must be acknowledged by both parties alike to have been a man of immense energy and resource, and of great organising power, who unquestionably had the full courage of his convictions, and was consistent and thoroughly sincere and disinterested in his aims. His temperament and the constitution of his mind made him feel impatience and scorn of the moderates, the calm, cautious watchers and waiters for opportunities. He was averse to nibbling advantage after advantage, and had no sympathy for the compromises and half-measures of statesmen and diplomatists. His was the spirit that burns the bridges behind it, stakes all on one critical throw, and puts forth all its energy to bring about a decisive and final result. Cavour was of an opposite temperament: he was essentially the cautious, calculating statesman. Hence the fundamental antagonism between the two men. Cavour was a man of aristocratic birth and training, and the levelling doctrines of the new republicanism were in the highest degree repugnant to him. No wonder then that he disliked Mazzini, the ardent apostle of equality, fraternity, and humanity, the uncompromising enthusiast of action. And no wonder too that Mazzini failed to sympathise with the methods of Cavour: he saw in them no ruling principle beyond advantaging the House of Savoy, no desire to labour for the people, no plan, no promise for their progress, and nothing like faith in their future. Nevertheless, on more than one critical occasion he abstained from embarrassing the Sardinian government, even when he did not approve of its proceedings. His own ability to govern is best evidenced in his successful organisation of the difficult forces of secret insurrection; his brief tenure of office at Rome was beset by so many untoward conditions as effectually to preclude him from showing his real mettle. Mazzini has been called the prophet of

Italian unity, Garibaldi its knight-errant, and Cavour the riveter of the bolts that finally united the *dissecta membra* of the nation. Perhaps it would be more correct to say that Mazzini prepared the soil, sowed the seed, and fostered the growing plant, that Garibaldi did the work of gathering in the ripe fruit, but that Cavour gained the final advantage of the harvest.

All Mazzini's writings are desultory in character, some few literary and critical, but most political, germane to the questions of the hour. His longest productions are *On the Duties of Man*, an excellent primer of ethics, and *Thoughts upon Democracy in Europe*, a discussion of the prominent schools of economics and socialism of the time. Apart from his eloquence, the features of his writing that most forcibly arrest attention are his manly, outspoken tone, his candid fairness—except sometimes when he is speaking of the moderates—his sterling love of justice and of freedom, but above all things else his keen and accurate insight into the historical tendencies of modern Europe.

The best source for Mazzini's life and works is the collected edition of his *Scritti, Editi ed Inediti*, 16 vols., the first eight (1861–74) prepared by himself, the last eight (1877–89) by Aurelio Saffi, his brother-in-law at Rome. The English *Life and Writings of Mazzini* (6 vols. 1864–70; new ed. 1890–91) is formed of selections from the *Scritti*. See also the memoir by E. A. Venturi (2d ed. 1877); Clarke, *Selected Essays of Mazzini* (1887); the Life by Bolton King (1903); and works by Luzio (Milan, 1905), Rodman (1922), Hinkley (1924).

Mead, a fermented liquor made from honey. The honey is mixed with water and fermented. Cottagers sometimes use the honey which remains in the combs after the usual processes of dropping and squeezing for making mead, which is a thin and very brisk, but at the same time luscious beverage. Mead has been in use from very ancient times, and was known equally to the polished nations of southern Europe and the barbarous tribes of more northern regions. The Greek name is *Hydromeli*.

Meade, GEORGE GORDON, American general, was born, 31st December 1815, at Cadiz, where his father was a merchant and United States navy agent till 1816. He graduated at West Point Military Academy in 1835, served against the Seminoles, but in 1836 resigned from the army and adopted the profession of civil engineer. In 1842 he was reappointed to the army, and fought in the Mexican War, but was mostly employed on survey duty and in the construction of lighthouses, until, on the outbreak of the Civil War, he obtained a brigade of volunteers. During the peninsular campaign he was severely wounded. He distinguished himself at Antietam and at Fredericksburg, and in 1863 was placed in command of the Army of the Potomac, superseding Hooker (q.v.) on the night of 27th June. A week later he had defeated Lee at Gettysburg and had prevented him carrying the war into the country north of the Potomac. Meade became brigadier-general in the regular army on 3d July, and major-general in 1864. After the war he commanded various military departments until his death at Philadelphia, 6th November 1872. There is an equestrian statue of him (1887) in Fairmount Park there. See work by Penny-packer (New York, 1901).

Meadow Saffron. See COLCHICUM.

Meadows-Taylor. See TAYLOR.

Meadville, capital of Crawford county, Pennsylvania, on French Creek, 113 miles by rail N. of Pittsburgh. It manufactures woollens, machinery, agricultural implements, &c., has oil-refineries, sawmills, ironworks, and large railway-shops, and is the seat of Allegheny College (Methodist,

founded 1815), and of a Unitarian theological school. Pop. 15,000.

Meagher, THOMAS FRANCIS, Irish patriot and American soldier, was born in Waterford, 3d August 1823, son of a wealthy merchant. He was educated at the Jesuit college of Clongowes Wood in Kildare and at Stonyhurst, and early devoted himself to the patriotic cause as a prominent and fearless member of the Young Ireland party. In 1848 he was convicted of high-treason and sentenced to death, but was sent for life to Van Diemen's Land instead. He made his escape in 1852, studied law in the United States, but on the outbreak of the Civil War volunteered into the national army. In 1861 he organised the 'Irish brigade' for the Federals, and distinguished himself by his courage in the seven days' battles around Richmond, at the second battle of Bull Run, at Fredericksburg, and at Antietam. After the war he became secretary of Montana territory, and, while taking measures as temporary governor to keep the hostile Indians in check, fell from the deck of a steamboat into the Missouri, near Fort Benton and was drowned, 1st July 1867.

Meal. See BREAD.

Meal-tub Plot, a conspiracy fabricated in 1679 by Thomas Dangerfield to gain credit as an informer equal to that of Titus Oates and Bedloe. The son of a Roundhead farmer, he was born about 1650 at Waltham in Essex, and he had first started with the baseless assertion that the Presbyterians were conspiring to destroy the government and set up a republic. When this was discovered to be a lie he was flung into Newgate, whereupon he rounded at once upon the Roman Catholics, declaring that the pretended Presbyterian plot was only a cover for their own design upon the king's life, and that the papers would be found concealed at the bottom of a meal-tub in the house of one Mrs Cellier, who, together with Lady Powis, was actually tried and acquitted for the plot. Dangerfield himself was whipped and pilloried in June 1685, and on his way back from Tyburn was killed by a blow in the eye from the cane of a barrister, Robert Frances, who was executed for the murder.

Meal-worm, the larva of a small black beetle, *Tenebrio molitor*, allied to the common Blaps (q.v.). Both adults and larvæ are too common about bakeries, granaries, and stores, for the eggs are laid in meal, flour, and similar food-stuffs, on which the emerging larvæ feed voraciously. The adult resembles Blaps, and is about half an inch long; the larva is decidedly longer, thin and round, yellowish in colour. An American species, *T. obscurus*, has also become common in Britain. The preventive is thorough cleanliness. The meal-worms are often used as food for cage-birds.

Mealy Bug (*Coccus adonidum* or *Dactylopius longispinus*; see COCCUS), an insect naturalised in our hothouses, and very commonly found on such plants as Stephanotis and Camellia, orchids and pine-apples. The young appear like small reddish-brown moving specks on the leaves and small branches, to which they afterwards affix themselves by the beak. As they grow older they become darker in colour, and are covered over with a white powdery-looking substance. After fertilisation, which usually takes place in spring, the female, remaining in the position described, lays her eggs between her body and the surface of the plant, after which her body shrivels up until it forms a covering for the mass of eggs, rendered more effectual by the large amount of cottony material formed over it. The young can be seen developing in scores in the midst of this material, from which they afterwards free themselves, and run about on the plant. The Mealy Bug is disliked by gardeners

chiefly on account of the amount of dirt that collects round it on the leaves and branches, and the injury it does to the flowers and fruit. Lightly syringing the plants with soft soap and quassia solutions with a little paraffin oil in addition is generally sufficient to check the ravages of this little pest, especially if put on before the larvæ acquire their mealy coats. On valuable plants the solution should be painted on with brushes. Tobacco smoke proves useful in the early stages.

Mean, in Mathematics, is a term interpolated between two terms of a series, and consequently intermediate in magnitude. The Geometrical Mean (q.v.) of two numbers is always less than their Arithmetical Mean (q.v.) and greater than their Harmonic Mean, and the geometric mean is itself a geometric mean between the two others.

Meanee. See MEEANEE.

Mearns. See KINCARDINESHIRE.

Measles (known also as RUBEOLA and MORBILLI) is one of the group of infectious diseases termed *Exanthemata* (q.v.), because they are accompanied by a characteristic eruption which appears upon the surface of the body. It is communicable from person to person, chiefly in the early stage when it is indistinguishable from an ordinary cold; and it seldom occurs more than once in the same individual. Its period of incubation—i.e. the time that elapses between exposure to the contagion and the first appearance of the febrile symptoms which precede the eruption—is usually about a fortnight; then come lassitude and shivering, which are soon followed by heat of skin, increased rapidity of the pulse, loss of appetite, and thirst. The respiratory mucous membrane is also affected, and the symptoms are very much the same as those of a severe cold in the head, accompanied by a dry cough, a slight sore throat, redness and watering of the eyes, and sometimes tightness of the chest.

The eruption which is characteristic of the disease usually appears upon the fourth day from the commencement of the febrile symptoms and the catarrh—seldom earlier, but occasionally later. It is a rash, consisting at first of red papules of various sizes, which, as they multiply, coalesce into crescentic patches. It is two or three days in coming out, beginning on the face and neck, and gradually travelling downwards. The rash fades in the same order as it appears; and, as it begins to decline three days after its appearance, its whole duration is about a week. The red colour gives way to a somewhat yellowish tint, and the cuticle often desquamates slightly.

Measles is distinguished from Scarlet Fever (q.v.) or scarlatina (1) by the presence at the outset of catarrhal symptoms, which do not occur in the latter disease, at any rate prior to the eruption; (2) by the absence of the characteristic throat-affection, which always accompanies well-marked cases of scarlet fever; (3) by the character of the rash, which in measles is said to present somewhat the tint of the raspberry, and in scarlet fever that of a boiled lobster; which in measles appears in crescentic patches, and in scarlet fever is universally diffused over the parts affected; which in measles usually appears on the fourth day, and in scarlet fever on the second day of the disease.

In ordinary uncomplicated measles the prognosis is almost always favourable. The chief danger is from inflammation of the bronchial tubes spreading to the lungs; and in weakly children it may leave chronic pulmonary mischief behind it. No age is exempt from the disease, but it is much more common in childhood than subsequently. The reason probably is that most persons have it in

early life, and are thus protected from an attack at a later period.

In mild forms of the disease nothing more is requisite than to keep the patient on a low diet, attend to the state of the bowels, and prevent exposure to cold, which is best accomplished by keeping him in bed with the ordinary warmth to which he is accustomed in health. While the eyes are red and irritable, it is desirable that he should be shaded from the light. If the chest-symptoms become urgent, they must be treated according to their nature. Bronchitis (q.v.), sometimes extending into Pneumonia (q.v.), is most to be feared. If the eruption disappear prematurely, it may sometimes be brought back by placing the patient in a warm bath. In such cases stimulants are often required, but must, of course, only be given by the advice of the physician. The patient must be carefully protected from exposure to cold for a week or two after the disease has apparently disappeared, as the lungs and mucous coat of the bowels are for some time very susceptible to inflammatory attacks. In some cases considerable debility remains for a long time after the attack; and the hearing is very liable to injury from inflammation of the middle ear, often accompanied by perforation of the drum and a purulent discharge.

German Measles is a name somewhat loosely used of a disease, or possibly several diseases, resembling measles, but milder and less prolonged. The incubation period is about three weeks, there is swelling of the glands as well as a rash which appears on the second day and lasts about a week.

Measures. See WEIGHTS AND MEASURES.

Meat, DISEASED, may not be sold under heavy penalties. The Public Health Acts, 1875, &c., regulate the powers of medical officers and inspectors of nuisances to examine game, flesh, milk, &c., and to have it destroyed, if unfit for human food, by order of a justice. See BOTULISM, PTOMAINES, PYÆMIA, TAPEWORM, TRICHINA, &c.

Meath, a maritime county of Leinster, Irish Free State, bounded on the east by the Irish Sea for 10 miles and by the counties of Dublin and Louth; area, 906 sq. m., of which only a small proportion is waste, bog, &c. Maximum measurements, north to south, 40 miles, east to west, 47 miles. Pop. (1841) 183,116; (1861) 110,373; (1881) 87,469; (1901) 67,497; (1911) 65,091, of whom 60,000 were Roman Catholics. The soil is a rich loam, and extremely fertile; but the extent under crops (chiefly oats and potatoes) is much exceeded by the area devoted to pasture. The surface is for the most part undulating, being the eastern part of the great limestone plain of Ireland. The chief rivers are the Boyne and Blackwater; the Royal Canal passes along the southern border of the county. The principal towns are Trim, Navan, and Kells. A little linen and coarse woollen is manufactured. Anciently Meath, which included West Meath, Longford, and parts of the adjoining counties, formed one of the kingdoms into which Ireland was divided, the royal seat being Tara (q.v.), where ancient earthworks still remain. After the English invasion it was occupied by Strongbow, and was erected into a county palatine by Henry II., who conferred it on Hugh de Lacy. In the end of the reign of Henry VIII. it was separated into East and West Meath. Celtic remains abound along the Boyne and Blackwater. John's Castle at Trim is one of the most extensive monuments of English rule in Ireland. There are a round tower and sculptured crosses at Kells, a round tower at Donoughmore, and monastic ruins survive at Bective, Clonard, Duleek. Meath returns three members to Dáil Éireann.

Meaux, a French town in Seine-et-Marne, on a height above the river Marne, 28 miles ENE. of Paris. In its noble Gothic cathedral (12th to 16th century, but still unfinished) is the grave of Bossuet (q.v.), bishop for twenty-three years. There is a large trade with Paris in corn, flour, cream-cheeses, &c. Meaux was besieged by the serfs of the Jacquerie (1358), and captured from the League (1594). During the Great War it was slightly damaged by shell-fire, and in September 1914 fell just within the extreme limit of the German advance on Paris. Pop. 14,000.

Mecca (also anciently called *Becca*), the Makoraba of Ptolemy, is one of the oldest cities of Arabia and the capital of the Hejaz, and as a holy city and focus of pilgrimage it may be called the metropolis of Islam. It is situated in 21° 30' N. lat. and 40° 8' E. long., 245 miles S. of Medina and 65 E. of Jiddah, its port on the Red Sea, in a narrow barren valley, surrounded by bare hills penetrated by two passes, and so secluded from observation that it is not visible until closely approached. The barrenness of the soil compelled the inhabitants to go outside for provisions, and the command of the principal caravan roads, both from north to south and from the coast to the highlands, gave the Meccans unusual facilities for commerce, and thus from a very early period the city was a notable trading centre. But the chief cause of the prosperity was its reputation as a holy place, possessing sacred objects, which well repaid a pilgrimage; though whether the original attraction was the Black Stone or fetish of the Kaaba, or the medicinal spring Zemzem, is a matter of dispute. The city itself, which is mainly modern owing to the frequent devastations caused by the winter torrents from the hills around, is about 1½ miles long and from ½ to ¾ of a mile wide, and is divided into the upper and lower city. Along and beyond it runs the celebrated sacred course, a broad road extending from Safa to Marwa, which is run over by all pilgrims, and also forms a frequented bazaar. The streets are broad and airy, but unpaved and filthy, and the houses, climbing the hills on either side, are of stone, and well built, sometimes three or four stories high, with flat roofs and overhanging lattice-windows. The interiors are well kept, since the greater part of Mecca is devoted to the annual pilgrimage, which is the main support of a multitude of lodging-house keepers, guides, and the other attendants of a fashionable sanctuary. There are charitable lodgings for the poorer pilgrims, and also public baths, and a hospital. Sanitation, if long neglected, is improving, and there is plenty of water. Provisions, meat, fruit, &c., are readily procured from neighbouring parts of Arabia. The population, which is notorious for its vice and corruption of every sort, is given as 70,000; but these are normally reinforced by at least some 200,000 pilgrims a year. The latter, however, are not numerous enough to satisfy the natives, who fleece them without remorse, and are too idle to supplement their extortions by any industry more vigorous than the manufacture of sacred relics. The Great Mosque of Mecca stands in the broadest part of the valley, and consists of a large quadrangle, capable of holding 35,000 persons, surrounded by arcades or cloisters, with pillars of marble and granite, &c., and entered by nineteen gates surmounted by seven minarets. In the centre is the Kaaba (i.e. cube), which was the temple of Mecca ages before the time of Mohammed, and then attracted pagan pilgrims just as now it draws thousands of Moslems. It has been twice rebuilt in historical times (most recently in 1627), but the old form has been preserved. It is about 40 feet long, 33 feet wide, and 50 feet high. When

Mohammed converted the heathen shrine into a Mohammedan focus the original notion of an idol temple with a miraculous fetish was abandoned, and the legend was invented that the Kaaba was built by Abraham on the occasion of the outcasting of Ishmael. The celebrated Black Stone is apparently a meteorite, about 9 inches long, built into the south-east corner at the proper height for kissing. There is also a 'Southern Stone,' of only inferior sanctity. The pilgrim circumambulates the Kaaba seven times, kisses the Black and touches the Southern Stone, and also goes round the Hijr or semicircular enclosure containing the so-called graves of Hagar and Ishmael. The Kaaba has always been richly decorated, and externally has long been annually re-covered (leaving only apertures for the two stones) with handsome brocaded hangings—the Kiswa, popularly known

Stone, and kept it for twenty-two years. Mecca afterwards fell under the influence of whatever dynasty—Fatimite, Ayyūbite, or Mameluke—happened to rule in Egypt; and thus it came into the possession of the Ottoman sultans, whose power, however, was nominal, whilst the real governor was the sherif, or reputed head of the descendants of the Prophet, who long held the chief authority in the Hejaz. The Sherif Husein ibn Ali in 1916 made himself independent king of the Hejaz, but in 1924 was forced to abdicate, and was succeeded by Ali, his eldest son, under whom, in October 1924, Mecca was captured by the sultan of Nejd. Few non-Mohammedans have entered Mecca; Ludovico di Varthema, an Italian, did so in 1503, and Joseph Pitts, an Englishman, about 1680; Burekhardt (in 1814–15) and Burton (in 1853) have left the best accounts.

Pilgrims round the Kaaba. (From a private Photograph.)

as the 'Holy Carpet'—brought with much state by the Egyptian Hajj (q.v.) at the same time as the traditional Mahmal, an empty covered litter emblematic of Egyptian sovereignty. The other chief decorations are the silver-gilt door, seldom opened, the marble inlay and silver-gilt plating and silk hangings of the interior, which contains little of interest. Hard by, and also within the court, is the celebrated well of Zemzem, a deep shaft covered by a cupola; the tepid water of which may once have been mineral, and is still regarded as miraculous, although the largest item in its present analysis consists of sewage matter. This important attraction for pilgrims was long lost, but was rediscovered by Mohammed's grandfather. Another object of veneration is 'Abraham's Stand,' the stone of which, with the imprint of his foot, is concealed from view. Outside the Great Mosque are no sacred or antiquarian buildings of importance, though several houses are pointed out by the guides as dwellings of persons famous in the early days of Islam. In the time before Mohammed Mecca was under the control of the Kosaites, and then of the Koreish, from whom the Prophet reconquered it in 627, five years after his Flight or Hegira (q.v.) therefrom. It long remained under the rule of the khalifs, who spent large sums in its adornment. In 930 it was sacked by the Karmathians, who carried off the Black

Stadt Mekka* (1857–59); Burton, *Pilgrimage* (1855; new ed. 1898); Burekhardt, *Travels in Arabia* (1829); Wavell, *A Modern Pilgrim in Mecca* (new ed. 1918).

Mechanics is the science which treats of the nature of forces and of their action on bodies, either directly or by the agency of machinery. See **FORCE**, **ENERGY**, **DYNAMICS**. The action of forces on bodies may be in the form of pressure or pull or of impulse, and may or may not produce motion. When the forces are so balanced as to preserve the body affected by them in a state of equilibrium, their actions are investigated in that branch of mechanics called **Statics** (q.v.); when

motion is produced, they are considered under the head of **Kinetics** (see **DYNAMICS**). See also the articles on **Kinematics**, **Hydrostatics**, and **Hydrodynamics**.

Machines are instruments interposed between the moving power and the resistance, with a view of changing the direction of the force, or of modifying its amount. Machines are of various degrees of complexity; but the simple parts, or elements of which they are composed, are reducible to a very few. These elementary machines are called the **Mechanical Powers**, and are usually reckoned as six in number, three being primary—viz. the *lever*, *inclined plane*, and *pulley*; and three secondary, or derived from the others—viz. the *wheel-and-axle* (derived from the lever), the *wedge*, and the *screw* (both derived from the inclined plane). What is special to each machine will be found under its name.

Mechanics' Institutes, voluntary unchartered associations of mechanics or working-men for the purpose of providing themselves, at small individual cost, with instruction in elementary and technical branches of knowledge, by means of a library, reading-rooms, classes, and lectures. The germ of the **Mechanics' Institute** was a class for journeymen mechanics formed by Dr Birkbeck (q.v.) at Glasgow in 1800; but the first **Mechanics' Institute**, properly so called, was

organised also by Birkbeck in London in 1824. The original aim was to teach mechanics the principles of their respective trades. Subsequently the basis was enlarged, and the giving of a general education aimed at. The institutes were wholly or in great part self-managed. Out of them have grown, through the introduction of means of recreation, the Working-men's Social Clubs and Educational Institutes.

Mechanism. See LIFE.

Mechtarists, a congregation of Armenian Christians who entered into communion with the Church of Rome, when Clement XI. was pope, in 1712. They derive their name from Mechtar (i.e. the Comforter) da Petro (1676-1749), who in 1701 founded at Constantinople a religious society for raising the intellectual and spiritual condition of his countrymen, and for diffusing a knowledge of the old Armenian language and literature. Two years later, however, their Uniati propaganda led to their removal to the Morea, and thence, on the conquest of that portion of Greece by the Turks in 1715, to Venice, which in 1717 granted them the island of San Lazzaro. Their most useful occupation is printing the classic writings of Armenian literature, as well as valuable editions of Armenian translations of works by Ephraem Syrus, Philo, Eusebius, and other writers, of which the Greek and Syriac originals have been lost. At San Lazzaro they possess a large and valuable library of oriental works, and at Vienna (since 1810) an academy, with a printing-office, &c., to which non-Armenians are admitted. See Langlois, *Le Couvent Arménien de Saint-Lazare de Venise* (1863).

Mechlin. See MALINES.

Mecklenburg, the common name of two states, formerly grand-duchies, of Germany, distinguished as MECKLENBURG-SCHWERIN and MECKLENBURG-STRELITZ, and situated between the Baltic on the N. and Brandenburg on the S., whilst Pomerania lies on the E. and Sleswick-Holstein and Lübeck on the W. Mecklenburg-Schwerin is a compact territory, abutting on the Baltic for 65 miles, its area being 5197 sq. m. (much less than Yorkshire). Mecklenburg-Strelitz (1144 sq. m.) consists of two detached portions—the former grand-duchy of Strelitz, SE. of Mecklenburg-Schwerin, and the former principality of Ratzeburg, wedged in between Schwerin and Lübeck. The region forms part of the great North German plain, but is crossed by a low ridge of hills from the south-east to the north-west, the water-parting between numerous small rivers that drain to the Elbe and to the Baltic. Along the line of this ridge there are more than 500 lakes, some of fairly large size. Canals, too, connect many of the lakes and navigable rivers, especially towards the Elbe. Except for sandy tracts and turf moors the soil is fertile; agriculture is the chief occupation. The merino sheep are the finest in Germany. There is some iron-founding, making of agricultural implements and tiles, manufacturing of beet-root sugar, distilling, brewing, and tanning. Amber is obtained on the coast and from some of the lakes, and peat is dug. The chief ports are Wismar and Rostock (Warnemünde), both in Schwerin. The population of Schwerin in 1890 was 578,342; in 1900, 607,770; in 1919, 657,330: of Strelitz in 1890, 97,978; in 1900, 102,602; in 1919, 106,394. The rural population are almost entirely Germanised Slavs, the former nobility and the town-dwellers for the most part of Lower Saxon stock. The popular dialect is Platt-Deutsch or Low German; the religious confession Lutheran. Rostock (q.v.), the largest town in Schwerin, has a university. The capital of Schwerin is Schwerin; of Strelitz, Neustrelitz. Society in Mecklenburg was till the revolution (1918) still

organised on a feudal basis, and in the early part of the 19th century was not so advanced as England in the 13th century; serfdom was abolished only in 1824. At the head of each grand-duchy stood a grand-duke; but both grand-duchies were represented in one and the same national assembly, which met every autumn at Sternberg and Malchin alternately. This body embraced all landowners (about 680), who also represented the peasantry and agricultural labourers, and representatives of forty-nine towns. The principality of Ratzeburg, and the towns of Wismar and Neustrelitz, had each an independent administration. A permanent college of nine members, representing the assembly, sat all the year round at Rostock. The executive was in the hands of four ministers in Schwerin, and one minister in Strelitz. No financial statements were published in either grand-duchy. In Schwerin, however, there were three separate budgets, one controlled by the grand-duke, one, very small, controlled by the estates, and one by both parties in common. As republics the two states have each a diet, elected by a general equal direct vote, with proportional representation. The evils under which the country workmen suffered in the middle of the 19th century, and of which Fritz Reuter, the great Platt-Deutsch writer, gives a painful description in his poem *Kein Hüsung*, have been greatly mitigated. The restraints imposed upon marriage by the landowners led to a relatively high proportion of illegitimate children. Reuter's works give admirable pictures of the semi-patriarchal, semi-feudal life of his native country.

In the 6th century Slavic races settled in the districts now called Mecklenburg, which had just been left vacant by the Vandals. From the 9th to the 12th century the German emperors and the Saxon dukes attempted at different times to convert the inhabitants to Christianity. The country was only definitely incorporated in the German empire in 1170. It was divided over and over again, from 1229 onwards for more than five hundred years, amongst different branches of the descendants of the original Slavic princes. Of these dukes (dukes after 1348) the only one deserving special mention is Albert III., who, called to ascend the throne of Sweden in 1363, was kept a prisoner for many years by Margaret, queen of Denmark, Norway, and Sweden. The Thirty Years' War ruined the independent peasant proprietors. Wallenstein casting covetous eyes upon the duchies, they were sold (1628) to him by the emperor, but were restored to their dukes in 1635. The two lines of Mecklenburg-Schwerin and Mecklenburg-Strelitz date only from 1701; in 1755 they agreed that the line which survived longest should inherit the territories of the other, and when both became extinct Prussia should be heir. The title of grand-duke was assumed by both reigning dukes in 1815. The year 1848 brought disturbances and tumults in Mecklenburg; a representative assembly was called together, and other reforms initiated; but the reaction of 1850 and following years restored things to their original condition. The two states were again agitated by reform questions in 1871-78. The grand-dukes promised a constitution in 1907. On the death of the grand-duke of Mecklenburg-Strelitz in February 1918, the grand-duke of Mecklenburg-Schwerin claimed the succession. In November, however, both states became republics.

Meconium (Gr. *mēkōn*, 'a poppy'), the inspissated juice of the poppy. *Meconic Acid* is an acid present in Opium (q.v.) to the extent of about 4 per cent. in combination with the alkaloids.—Meconium is also the name given to the matter first discharged from the bowels of a new-born infant.

Meconopsis, a genus of Papaveraceæ, represented in Britain by the yellow-flowered Welsh poppy, *M. cambrica*.

Medal (the same word as *metal*, through a Low Latin *medalla*), a piece of metal in the form of a coin, not issued or circulated as money, but struck to preserve the portrait of some eminent person or the memory of some illustrious action or event. Large medals are termed medallions; and works rectangular in form are known as plaques or plaquettes, according to their size. The study of medals, which forms a branch of the science of numismatics, is interesting in an historical and antiquarian point of view, and important as illustrating the contemporary state of art. Like coins, medals are made in gold, silver, and copper, and some also consist of lead and alloys of other base metals. As they are generally produced in very limited numbers compared with coins, other methods of preparing them than by striking are available; and while all classical medals, and the bulk of those of modern times, are made in the same way as contemporary coinage, many of the most

a scale of one-half the original size the obverse and reverse of one of the most famous medals of Pisano. It celebrates the visit of the Eastern emperor, John VIII. Palæologus, to the Council of Florence in 1439; the legend on the obverse being in Greek, and the reverse inscription, *Opus Pisani Pictoris*, being also repeated in Greek. Generally speaking, it may be said that all mediæval medals, previous to the 16th century, were made by casting in the *cire perdue* process; and it was not till the beginning of the 16th century that medals struck from engraved dies, like coins, were issued, the first so produced being the medal of Pope Julius II., by Francia, struck about 1506. The larger medals of the 16th century, however, continued to be cast. The most elaborate and beautiful of the struck medals of the 16th century were the work of Benvenuto Cellini; and it may be remarked that with the introduction of dies for medal-striking the work passed into the hands of gem-engravers and jewellers, whose methods and excellences lie in quite a different direction from those of the 15th-century artist-medallists.

Next to Italy, Germany was the country in which the medallie art flourished in mediæval times, Nürnberg having been a centre from which many important works were issued. Of the German school, Albrecht Dürer was the most famous of the early exponents. In Holland a remarkable series of *jettons* or medalets were issued in the 16th and the early part of the 17th century which give a record of the important events of which that country was then the theatre. In the 16th century the most important medals of French origin were

Fig. 1.

Fig. 2.

important and valuable of the mediæval medals were cast by the *cire perdue* process (see FOUNDING). Important medals have also been made by *striking-up* or *repoussé* work (see REPOUSSÉ), and highly esteemed works are also made simply by engraving. The earliest medals are medallions of ancient Rome, existing examples of which are principally in bronze, though some are in silver and in gold. They vary in size, being mostly about $1\frac{1}{2}$ inch in diameter, but in weight they are so diverse as to exclude the notion that they were ever circulated as money. Medallions, prior to the time of Hadrian, are rare and of great value, one of the most beautiful and most famous being a gold medallion of Cæsar Augustus; from Hadrian to the close of the empire they are comparatively numerous. In some of them a ring or rim of lighter-coloured metal (brass or orichalcum) surrounds the centre of bronze, and the inscription extends over both metals.

From the fall of the Roman empire till the end of the 14th century there is a blank in the production of medals. The revival of the medallie art was one of the first fruits of the Renaissance movement, and practically its earliest, as for all times its greatest exponent was Vittore Pisano (c. 1380-1456), the painter of Verona. His medallions, generally marked *Opus Pisani Pictoris*, and those of his numerous followers, including Matteo de Pasti, Guacialotti, Sperandio, Sangallo, and many others, are distinguished by their vividness of sculptural portraiture, and their singular breadth and simplicity of treatment. Figures 1 and 2 show to

produced by Jacques Primavera and Germain Pilon, and in the succeeding century Briot and Dupré were the great medallie portrayers of contemporary personages and events. English medals begin only with Henry VIII., and from Edward VI. onwards there is an unbroken succession of coronation medals. The earlier medals are cast in a very inferior manner, and are certainly not the work of native artists; indeed, it is not till the period of Elizabeth that we find native talent developed in the direction of medal-working, and even thereafter it was largely to Dutch, French, and Italian artists that the principal English medals were due. The Scottish coronation medal of Charles I. by Briot is the first medal struck in Britain with a legend (*Ex Auro ut in Scotia reperitur*) on the edge. The medals of the Commonwealth and Charles II. are principally by Rawlins and the brothers Simon, and under Charles II. the three brothers Rottier did important medallie work in England. In the 18th century J. A. Dassier, a native of Geneva, executed a series of medals of English monarchs from the time of William I., and other important works were the production of Croker, Richard Yeo, and Thomas Pingo. Of 19th-century English medals the best are due to the Italian Pistrucci and to Thomas and William Wyon and their successors.

Official medals at the present day are principally issued to the fighting services. To these ribbons distinctive in colour are attached. The first war medal given in England was the 'Ark in flood medal' bestowed by Queen Elizabeth in 1588 on

naval heroes. The first English military medal was granted by Charles I. in 1643, and in 1650 an oval medal was executed by order of parliament for distribution amongst Cromwell's officers and soldiers engaged in the battle of Dunbar. Medals have been distributed to the troops in every victorious engagement and campaign since 1793 till the present time, but previous to the reign of Queen Victoria the Waterloo medal was the only one of this series struck. It was issued by order of the Prince Regent in 1816, and conferred on every officer and soldier present at the battle. The medal is of silver, with the head of the Prince Regent on the obverse, and on the reverse a figure of Victory seated on a pedestal, inscribed 'Waterloo,' with, beneath, the date June 18, 1815, and above, 'Wellington.' The Peninsular medal, for military services between 1793 and 1814, was issued only by the Queen in 1847, and conferred upon every surviving officer and private present at any battle or siege during these years. It carries no fewer than twenty-eight clasps for as many separate engagements, the first of which is Egypt, 1801. Long-service and good-conduct naval and military medals of silver were instituted in 1830 and 1831. The Victoria Cross (q.v.) was instituted in 1856. During the Great War various new medals for distinguished service in the naval and military forces were instituted, as also the first medals for such service in the air force; the 'Victory Medal' was a commemorative medal common to the Allies, and additional to the ordinary British War Medal, 1914-18. Similar medals for military, naval, and air force services are issued by foreign powers.

Medea, in Greek legend, a famous sorceress, the daughter of Æetes, king of Colchis, and of the Oceanid Idyia, or of Hecate. When Jason, the leader of the Argonauts, came to Colchis in search of the Golden Fleece, she fell in love with the young hero, helped him to obtain the Fleece, and fled with him. She prevented her father from pursuing by killing her brother Absyrtus and strewing the sea with his limbs. She avenged her husband upon the aged Pelias by persuading his daughters to cut him in pieces and boil him in order to make him young again. Being deserted by Jason for Glauce or Creusa, daughter of Creon, king of Corinth, she revenged her wrongs by sending to her rival a poisoned robe or diadem which destroyed both her and her father. Medea then slew the children she had borne to Jason, and fled to Athens in a chariot drawn by dragons, which she obtained from Helios. There she was received by Ægeus, to whom she bore Medos; but, afterwards being compelled to flee from Athens, she took Medos to Aria, the inhabitants of which were thenceforth called Medes. She finally became immortal, and the spouse of Achilles in the Elysian Fields. The story of Medea was a favourite theme of the tragedians, but only the masterpiece of Euripides has come down to us. It was treated by Corneille and Grillparzer in drama, and by Cherubini in opera.

Medellín, (1) a small town of Spain, the birth-place of Cortes, on the Guadiana, 52 miles E. of Badajoz.—(2) The second city of Colombia, capital of the department of Antioquia, lies in a lovely mountain-valley, 4850 feet above the sea, and 150 miles NW. of Bogotá. It is a handsome town, with a cathedral, university, college, school of mines, &c. It is the chief industrial (cotton, woollen, tobacco, panama hats, crockery) and coffee centre of the country, and trade in gold and silver is important. Pop. 80,000.

Medford, a city of Middlesex county, Massachusetts, on the Mystic river and lakes, 5 miles N. by W. of Boston, has several historic buildings and a Universalist college; pop. 39,000.

Media, in ancient times, corresponded to the north-west of modern Persia. The Medes were an Aryan people like the Persians; their state religion was Zoroastrianism, and the Magi (q.v.) its priests. They were at first a bold and war-like race, very skilful with the bow, and noted horsemen. The Median tribes, who seem to have been in part subject to the king of Assyria, began towards 700 B.C. to be cemented together under a chief named Deioces (Dajaukku), who chose as his capital Ecbatana (q.v.), identified with the modern Hamadan. Their power grew stronger under his son Phraortes, who subdued the Persians, but perished in war with the Assyrians. Cyaxares, the son of Phraortes, renewed the war against Assyria, but it was interrupted by an invasion of Media by the Scythians. Having treacherously murdered their chiefs, he expelled their warriors. Then, in alliance with Nabopolassar, king of Babylon, he overthrew the Assyrian empire by capturing Nineveh about 607 B.C. Having annexed the northern provinces of the Assyrian empire, he began a war against Lydia; but the eclipse of 28th May 585, the same which had been foretold by Thales, terrified both parties into peace. Cyaxares was succeeded by his son Astyages. Against him the Persians, under their prince Cyrus, revolted about 550 B.C., and, being joined by a portion of the Median army under a chief named Harpagus, they took Ecbatana and deposed the Median king. From this time the two nations are spoken of as one people. Ecbatana became the summer residence of the Persian kings. After the death of Alexander the Great (323 B.C.), the north-western portion (Atropatene) of Media became a separate kingdom, which existed till the time of Augustus. The other portion, under the name of Great Media, formed a part of the Syrian monarchy. In 147 B.C. Mitridates I. took Great Media from the king of Syria, and annexed it to the Parthian empire. About 36 B.C. it had a king of its own, named Artavasdes, against whom and his ally, Phraates IV. of Parthia, Mark Antony engaged in a disastrous campaign. Under the Sassanian dynasty the whole of Media was united to Persia (q.v.).

Medical Jurisprudence, also called Forensic Medicine, is the branch of medicine which brings medical science to bear on legal questions, in determining criminal and civil responsibility. It has regard mainly either to civil rights or to injuries to the person. See BLOOD-STAINS, POISONING, &c.

Medici, a distinguished Florentine family which attained to sovereign power in the 15th century,

owed its earliest distinction to the success with which its members pursued various branches of commerce, and the liberality which they showed in devoting their wealth to the public good. Their well-known arms, representing six balls (from whence their war-cry of 'Palle'), were popularly but without reason believed to represent pills, as their name to show that they had been originally apothecaries. In 1465 Louis XI. of France honoured the Medici by conferring on them the right to wear the French fleur-de-lis on one of the balls. From the beginning of the 13th century the Medici took part in the government of their native republic, and from the period (1378) when Salvstro de' Medici was elected gonfaloniere the family rose rapidly in greatness. It was, however, Giovanni (born 1360) who amassed the immense fortune, and by his generosity and affability gained the position of influence hitherto unparalleled in the republic, to which his sons Cosimo and Lorenzo succeeded. With Cosimo (1389-1464), surnamed *Il Vecchio* ('the Ancient') and '*Pater Patriæ*,' began the glorious epoch of the family; while from his brother Lorenzo was descended the collateral branch of the Medici which in the 16th century obtained absolute rule over Tuscany.

Cosimo's life, except during the brief period when the Albizzi and other rival families succeeded in successfully opposing the Medici influence in the government and exiling him from Florence, was one uninterrupted course of prosperity. He was successful in his political alliances, and procured for Florence security abroad and peace from civil dissensions within her walls. He employed his great wealth in encouraging art and literature. He made Florence the most brilliant centre of the revival of classic learning which distinguishes the 15th century, he enriched her with splendid buildings, and gave unrivalled treasures to the great libraries which he founded. Although his all-powerful influence was not explicitly recognised in the state, and the form of government remained republican, Cosimo in reality was entirely master of the town, and filled the public offices with his partisans. He was succeeded by his son Pietro I., surnamed *Il Gottoso* ('Gouty'), who, feeble in health and in character, was assisted in the government by the precocious talents of his son Lorenzo (1448-92), afterwards famous in history as Lorenzo il Magnifico.

On his father's death (1469) Lorenzo and his brother Giuliano were recognised as '*principi dello stato*.' The growing power of the Medici had roused much envy amongst other great Florentine families; and in 1478 these malcontents, headed by the Pazzi and in league with the pope, Sixtus IV. (*Della Rovere*), who saw in the Medici a powerful obstacle to his schemes of temporal aggrandisement, formed a plot to overthrow their power, known as the conspiracy of the Pazzi. Only Giuliano was victim of the assassins who were to have killed both brothers during service in the cathedral, and the popularity of Lorenzo was increased by the courage and judgment shown by him in this crisis. Lorenzo was a worthy descendant of his famous grandfather, just in his government, magnanimous to his enemies, and not only a munificent patron of art and literature, but himself a man of wide culture and a distinguished lyric poet. To enlarge on the institutions, universities, and schools founded by him, and on the famous names of painters, sculptors, architects, philosophers, and poets who surrounded him would be to write the history of the Renaissance. He was one of the most zealous promoters of the art of printing, and established under Cennini a printing-press in Florence. Although he used his power in the state well, yet he sapped the existing forms

of government; and, in seeking only the advancement of his family to more absolute power, he left Florence at his death weakened and ready to be the prey of her enemies during the troublous times which began with the 16th century.

Lorenzo left three sons, Pietro, Giuliano, and Giovanni. His eldest son, Pietro II. (born 1471), possessed neither capacity nor prudence, and showed himself treacherous alike to friend and foe. He allied himself with the king of Naples against Lodovico Sforza of Milan, and the latter in 1492 called to his aid Charles VIII. of France and his army (see ITALY). Pietro, terrified at the advance of the powerful invader, hastened to meet the French troops on their entrance into the Florentine dominions, and surrendered to them Pisa and Leghorn. The magistrates and people, incensed at his cowardice and treachery, drove him from Florence and declared the Medici traitors and rebels, and deposed them from participation in the government. Pietro was drowned (1503) in the Garigliano, near Gaeta, having joined the French army in their attempted conquest of the kingdom of Naples. All efforts of the Medici to regain their power in Florence were vain until in 1512 the pope, Julius II., consented to send the Spanish army to invade Tuscany. Prato, near Florence, was taken and sacked, and the Florentines, helpless and terrified, drove out their gonfaloniere, Piero Soderini, and recalled the Medici, headed by Giuliano II. (born 1478). In 1513 the elevation of Giovanni de' Medici to the papal chair under the name of Leo X. (q.v.) completed the restoration of the family to all their former splendour and reduced Florence to a papal dependency. Giuliano II. at the pope's desire surrendered the government to Lorenzo II., son of his elder brother Pietro II. Giuliano, created Duke of Nemours on his marriage with a relative of Francis I. of France, died in 1516. The young Lorenzo II., born 1492, and the last legitimate male descendant of Cosimo '*Pater Patriæ*,' on whom the pope had also conferred the duchy of Urbino, was feeble, arrogant, and licentious. He died in 1519 leaving only one legitimate child, a daughter, Catharine (q.v.), afterwards wife of Henry II. of France, who played a conspicuous rôle as regent during her son's minority. An illegitimate son, Alexander, born 1510, was afterwards duke.

The power now passed into the hands of the Cardinal Giulio de' Medici, a natural son of the elder Giuliano, assassinated in the conspiracy of the Pazzi; and Giulio was created pope in 1523 under the name of Clement VII. During the invasion of Italy by the Emperor Charles V. in 1527, and the consequent weakening of the papal power, Florence rebelled against the regents imposed on her by the pope, and expelled them along with the young Prince Alexander. The pope and emperor, however, soon made peace, and their united forces were directed against Florence, which, during the famous siege lasting ten months, made her last desperate and unsuccessful stand for liberty. After the surrender of the town, August 1530, Alexander de' Medici was proclaimed hereditary Duke of Florence. His reign was one of unparalleled license and tyranny. He was assassinated in 1537 by his cousin Lorenzino, a descendant of the collateral branch which had its origin in Lorenzo, brother of Cosimo '*Pater Patriæ*.' To this younger branch belonged also the next ruler of Florence, Cosimo I. (born 1519). He was son of the famous captain of free-lances, Giovanni delle Bande Nere ('of the Black Bands'). Cosimo, sometimes called the Great, possessed the astuteness of character, the love of art and literature, but not the frank and generous spirit of his greater predecessors. He was cruel and relentless in his enmities, but a just ruler. He

extended his territories, and in 1570 was created Grand-duke of Tuscany, and crowned by Pope Pius V. He died in 1574, and was succeeded by his son Francesco I. (born 1541). This duke possessed few of his father's abilities and many of his faults. He became a tool in the hands of his mistress, the unscrupulous Bianca Cappello, whom he married in 1578. The almost simultaneous death of Francesco and Bianca (October 1587) raised suspicions that they had been poisoned by the duke's brother and heir, the Cardinal Ferdinando. For Francesco's daughter, second wife of Henry IV. of France, see MARIE DE' MEDICI. Ferdinando I. and his son Cosimo II. were popular, and contributed to the prosperity of their country. But at the beginning of the 17th century the race rapidly degenerated; and, after several of its representatives had suffered themselves to become mere puppets in the hands of Austria or Spain, the family became extinct in 1737 at the death of its last male representative, Gian Gastone, the seventh grand-duke. His only sister, the Electress Palatine, the last of all the Medici, died in 1743.

See works cited at FLORENCE, Roscoe's works on Lorenzo and Leo X., and books by Reumont (trans. 1876), Armstrong (1896), Horsburgh (1908), Janet Ross (1910), and G. F. Young (1909).

Medicine. The healing art is found existing among the rudest savages of the present day, and in point of time is coeval with the earliest prehistoric peoples. Lucretius imagines for us the first attempts of early man to heal the injuries received in contest with wild beasts; and the 'Father of Medicine,' Hippocrates, has among his shorter works a treatise on *Ancient Medicine*. Prehistoric skulls are found showing signs of having been trephined with an instrument of flint, and Egyptian bodies from the time of the 5th dynasty still bear the splints with which attempts had been made to treat fatal injuries before death occurred.

In the early history of the highly civilised Euphrates valley regulations were made for the practice of surgery, and the amounts of fees were fixed on the stele of Hammurabi, king of Babylon, over 2000 years B.C.; also, many baked cuneiform tablets have been discovered bearing prescriptions and directions for the management of illness. Into this early medicine much ritual and invocation enters, so that the remedies are both material and theurgic. Egypt, at the time of the 18th dynasty (c. 1500 B.C.), possessed a well-developed system of medical practice. Here, again, medical methods were much involved with religious ritual, and apparently the practitioners of the art were much bound by conservative tradition. The Ebers Papyrus of this period is called the *Book of the Preparation of Medicines for all the Corporeal Parts of Individuals*. In this can be recognised such drugs as salts of lead, lime, soda, peppermint, cedar-wood oil, turpentine, gentian, opium, linseed, castor-oil, mustard, yeast; though many are unidentifiable. Among instruments and applications mentioned are the knife, the cautery, forceps, massage, plasters, poulices, enemata, inhalations, douches, and fumigation. From appearances found in mummies and in bodies buried in the sand, the important fact is clear that the processes of disease were much the same three thousand years ago as they are to-day. The names and portraits of practitioners holding high positions even at this early epoch have come down to us—e.g. Auta, Imhotep, Neneksekmet. The Israelites were in medical matters followers of the Egyptians, and, as with the latter, cleanliness and ritual form two dominant notes of their practice.

The sacred books of the Indians, which show the practices of many centuries B.C. (*Rigveda* and *Atharvaveda*), contain spells against the

demons of disease. Later, during the Brahmanical period extending up to 1000 A.D., medicine attained a high degree of rationalism and skill. The three leading names are those of Charaka, Susruta, and Vagbhata, whose lives are generally placed in the 1st, 5th, and 7th centuries respectively of the Christian era. The vital processes are supposed in Indian physiology to be actuated by air, bile, and phlegm, and health is regarded as due to a proper relationship of these. The materia medica of India was particularly rich in drugs, of which many have been imported into Western medicine. A great number of surgical instruments were employed, apparently with considerable skill, and the Indian surgeons were specially adept at cataract operations and reparative surgery by skin-grafting, methods which also found their way through the Arabs into Western surgery. Dietetics and bodily cleanliness played an important part in treatment, and much attention was given to antidotes for poisons, such as snake-bite, and to aphrodisiacs. It is hard to say how much the medicine of India owes to that of Greece. Many significant parallels exist between the two, and while it is probably not correct to assume, as many authorities do, that Indian medicine was derived indirectly from the schools of Greece, there was probably, even before the time of Alexander the Great, much mutual influence through the intercourse between Greece and India by way of Persia.

Chinese medicine, on the other hand, was formal, and its literature showed no advance with time. A large number of drugs were employed, such as rhubarb, aconite, opium, sulphur, and mercury, as well as many disgusting substances like the excrement of animals. There was little operative procedure beyond the application of burning cones or moxæ to the skin, and acupuncture with fine needles of gold or silver. Japanese medicine was originally derived from that of China, but with the remarkable assimilative power of this people, they quickly adopted Western medicine from the time at which they first were brought into contact with it in the 16th century.

Western medicine took its origin in Greece at the time when that country was at its highest intellectual development. Even in the *Iliad* of Homer (1000 B.C.) the medical man is said to be 'worth many others both to cut out arrows and to apply soothing remedies'; and again, in the *Odyssey*, the healer of the people is described as a welcome guest equally with the godlike minstrel and the builder of ships. The chief tutelary deity of the healing art among the Greeks was Apollo, but later his son, Asklepios (or Æsculapius), and Hygieia, daughter of the latter, received especial veneration, and many shrines of Asklepios were scattered throughout the Grecian world. Asklepios is generally represented bearing a staff round which a serpent, held sacred to him, twines; and his temples formed resorts for the sick, who, after sacrifices and other religious observances, practised the rite of 'incubation' or 'temple-sleep,' in the expectation that the method of their cure would be revealed in a dream. Before the 5th century B.C. the healing art was in the hands of three types of person. Firstly, there were the philosophers, usually identified with some special school, such as Thales of Miletus, Pythagoras of Krotona, Empedocles of Agrigentum. These made in many cases considerable contributions to both the theory and the practice of medicine. Secondly, the priests and priestesses in the temples of Asklepios, mentioned above, carried out a form of faith or mental healing, which was in great repute, though it is humorously satirised in the *Plutus* of Aristophanes. The large number of people intent on pleasure or healing, who frequented, for example, the shrine

of Asklepios at Epidauros, may be judged from the fact that outside the temple precincts stood an open-air theatre which held 12,000 persons, and a stadium which could accommodate 20,000 spectators. The third type of healer comprised the regular practitioners, who were bound together into Asklepiad guilds. The secrets of the medical art were conserved among the members of certain families with the pupils whom they admitted, and were handed down jealously from father to son. Instruction in the art began in boyhood; and before he was admitted to practice, the votary bound himself by the celebrated 'Hippocratic oath.' The practitioner, attended by his pupils, saw patients either at their homes or in his consulting-room (*iatreion*), which was provided with instruments, bandages, splints, medicines, and various pieces of apparatus required for such purposes as the reduction of dislocated joints. Some of the more celebrated physicians travelled from place to place as consultants, and many of the towns employed salaried medical officers at the state's expense.

Hippocrates (460-370 B.C.) is the most celebrated of these early Greek practitioners. Springing from an Asklepiad family in the island of Cos, he lived in Athens, a contemporary of Plato, Thucydides, and Pericles, and rendered valuable services to that city in connection with epidemics. In the general body of medical literature of his time a large number of treatises are attributed to him, the Aphorisms and the treatises on Fractures and Dislocations and on the Sacred Disease (Epilepsy) being the most celebrated. The striking features of his works are their rationalism, with an entire absence of the earlier mysticism and superstition; and the high position that he assigns to observation, with but little recourse to theorising. He notes carefully the history of his cases, the symptoms they present, and records many simple signs drawn from examination of the urine, the complexion, temperature, respiration, percussion, and auscultation by laying the ear on the patient's chest. Prognosis, or the foretelling of the course of the disease, assumed great importance in his eyes, and was intimately connected with his theory of critical days. Another theory which had been introduced by Pythagoras, that the humours or fluids of the body were the determining factors in disease, received great attention from Hippocrates, and long dominated medicine. Simple forms of diet held one of the chief places in treatment, ptisan or barley-water, honey in water, and diluted wine being the favourite forms of nourishment. Externally, cold affusions, the bath, massage, and, for wounds, boiled water or wine, are recommended. The drugs employed by Hippocrates were not many in number, but include some of Egyptian and even of Indian origin.

Following Hippocrates, the most noted names are those of Aristotle and Theophrastus, the former of whom made many discoveries in the structure and functions of the bodies of animals, the latter doing much the same for plants. According to the historian Pausanias, it was from Aristotle that his pupil Alexander the Great derived his great interest in medicine. The school of medicine at Alexandria was the most celebrated of the ancient world. Though it passed away leaving little record, many of its teachers, especially anatomists and surgeons, are mentioned by Celsus and Galen. Herophilus and Erasistratus, famous both as practitioners and as discoverers in anatomy, were its most celebrated representatives. About the beginning of the Christian era, the development of certain 'medical sects' is noteworthy. The *Dogmatists* were those followers of Hippocrates who made a theoretic system out of his doctrine of the humours

and qualities of substances. The *Empirics* went to the opposite extreme, and not only rejected reasoning and every form of theory as to the nature of disease, but denied that medicine could be founded upon the sciences of anatomy and physiology, trusting only clinical observation and their own experience in treatment. The *Methodists* formed a sect holding the belief derived from Asklepiades of Bithynia, that all disease is due to an improper arrangement of the particles and pores of the tissues; later modified by his pupil Themison to the idea of too great rigidity or too great laxity; treatment therefore became a matter of great simplicity, intended to restore the tissues to their proper soft or tonic state, as the case might be. An important adherent of this sect was Soranus of Ephesus, who wrote a text-book on obstetrics, preserved in a Latin translation. The *Pneumatists*, as a sect, held to a system dependent on the theory that all disease is due to some defect of the vital air; and the *Eclectics*, while closely allied to the latter, assumed the right to choose in any given circumstances the methods of treatment which seemed best to the individual. Rufus of Ephesus and Aretæus of Cappadocia, belonging to this sect, have left medical writings. The names of some of these sects have persisted to the present day, as applied to modern tendencies in medical theory.

At Rome in republican days medicine was little pursued, or rather a slight practical knowledge of medicine, conducted by herbs and simple surgical procedures, formed part of the general knowledge of every patrician. This is exemplified in the *De Re Rustica* of M. P. Cato. One patrician, A. C. Celsus, has left in his *De Medicina* a picture of medicine at the commencement of the empire as formed by Greek influences, which ranks with the works of Hippocrates and Galen as one of the chief monuments of classic medicine. In the first two of his eight books are given rules for diet and hygiene, the general causes, symptoms and prognosis of diseases, and a discussion of different forms of treatment. The third and fourth books deal with the treatment of general and local diseases, including insanity; books V. to VIII. deal with surgical matters, and include concise and clear descriptions of operations for hernia, lithotomy, couching the lens for cataract, and of the arrest of bleeding by ligation of vessels, treatment of wounds by various mild antiseptics, &c. Various other general Roman writers have dealt with the subjects of hygiene and of drugs—such as Vitruvius, who attributed many diseases, e.g. goitre, to drinking-water; Varro, who believed malaria to be due to infection with minute, invisible animals bred in marshes; and Pliny, who in his *Natural History* describes the properties of many important drugs. Dioscorides, an army surgeon under Nero, towards the end of the 1st century published a most complete and accurate account of all the remedies then in use, and from the clear descriptions that he gives of the plants, &c., almost all his remedies can be readily recognised at the present day. Scribonius Largus, physician to the Emperor Claudius, has left an excellent book of prescriptions.

Under the Roman empire physicians from the schools of Greece flocked to the imperial city, where their services were in great demand. Wealthy patricians employed slaves or freedmen, who had been trained in medicine, to attend their family and dependents. The various theatres, training-places for gladiators, and similar bodies had their special medical attendants. State or municipal medical officers (*archiatri*) were appointed both in Rome and provincial towns to attend the poor and perform other public offices. The army was well provided with medical officers, one for

every cohort, with legionary officers of higher rank. Specialism was pushed to an extreme, for not only was there a division into physicians and surgeons, but Galen mentions also oculists, aurists, dentists, hernia-specialists, lithotomists, gynaecologists, dermatologists, and others. Unfortunately there was no legal supervision of medical practice, and the practitioners belonged to all social grades, some of them presenting the most barefaced charlatanism. It forms a complaint both by Juvenal and Martial that the profession generally was in low repute, carpenters and smiths and undertakers flocking into it, often with only a training of six months.

Claudius Galen (131-200 A.D.) was the greatest figure in ancient medicine, and his works exercised so lasting an influence that they remained the chief authority in medicine to the Renaissance. This was partly due to their inherent worth, and partly because Galen's teleological conception of medical facts and his frequent praise of the Creator's wisdom and design appealed to the fathers of the early church. After a prolonged study of philosophy in his native Pergamos and of medicine at Alexandria, he settled in Rome; subsequently became the friend and physician of the Emperor Marcus Aurelius and numerous other persons in high positions; delivered public lectures, and above all was a man of boundless energy and an indefatigable writer on medical subjects. Galen was a fervent admirer of Hippocrates, whom he copied in the inductions as to treatment to be drawn from clinical signs; he also strove to set diagnosis upon a firm anatomical and physiological basis. His system errs, however, in being too complete: every question is provided with an answer, which gives his opinions a false appearance of infallibility. He divides diseases into three classes: (1) those affecting simple tissues like the muscles, nerves, or connective tissues; (2) those of the organs, such as heart, lungs, liver; and (3) those affecting the body generally, especially the four humours, blood, phlegm, bile, and black bile. When the humours are mixed in proper amount there is a state of health or 'eucrasia,' but as a rule the mixture is not correct, and the result is some form of 'dyscrasia' or special temperament, such as the sanguine, bilious, phlegmatic, melancholic, according to the humour in excess. The causes of disease he classified as (1) exciting, usually some external influence; (2) predisposing, usually some internal condition; and (3) proximate, which constitutes the disease. To illustrate his attitude by a modern example, in pneumonia the exciting cause would be the growth of bacteria in the lung, the predisposing cause the debility, weakness of the mucous membranes, &c., which permit of this, and the proximate cause would be the phenomena of inflammation in the lung which produce the illness. He placed great reliance on the examination of the pulse in diagnosis; and in treatment he elaborated a system of 'indications,' the chief of these being to remove the cause of the disease or prevent its action; secondly, if the symptoms were against nature, to treat these by contraries; otherwise to assist nature's efforts at cure; still other sources of indications were the patient's temperament, the external conditions, and—a curious point much in accord with some modern physicians—the patient's dreams. Drugs act, according to Galen, by their potential 'qualities' of heat, cold, dryness, or moisture, each of these being divided into four degrees; and drugs are to be given in opposition to these qualities as they are manifested in disease. Galen produced some 500 treatises, of which over 100 have come down to us. The chief of these are *On Practical Anatomy*, *On the Use of the Parts of the Body* (physiology), *On the Pulse*, *Compounding and*

Action of Simple Remedies, and *On Therapeutics*. The knowledge handed down by him from the Alexandrian school forms the foundation on which the superstructure of modern medicine is laid.

Since the followers of Galen regarded medicine as having reached an unsurpassable height in his teaching, little advance followed for many centuries after his time. Numerous well-known medical men, however, at Byzantium during the declining years of the empire made selections from the best writers, and of these compilations the most noteworthy are those of Oribasius (4th century), Aetius of Amida (6th century), and Paulus of Aegina (7th century). Whilst the decadent empire was losing all power of initiative, the Arabs, in the time of their flower from the 7th to the 13th century, warmly took up medicine. Much of their activity in this art consisted simply in translating and commenting upon the old Greek medical writers, but they also described some diseases for the first time, such as smallpox and measles (Rhazes), introduced important hygienic measures, founded large charitable hospitals, and brought from the East many new drugs and new clinical and therapeutic procedures. Their large hospitals possessed pharmacopœias or lists of selected drugs, and that of Mesuë of Damascus (11th century) was used by the Royal College of Physicians of London in framing their pharmacopœia during the reign of James I. Among the drugs introduced by these pharmacopœias are senna, rhubarb, camphor, cloves, cassia, musk, nutmeg, cubebs, orange, lemon, sugar, and new methods of preparing drugs are detailed, as, for example, the various volatile oils and alcohol produced by distillation, and the solution of drugs in syrups and tinctures. Among the greatest names of the Eastern Khalifate are those of Rhazes (10th century), Haly Abbas (10th century), and Avicenna (980-1036 A.D.); while in the Western Khalifate, Abulcasis (938-1013 A.D.), the great surgeon of this people, Avenzoar (12th century), and Averroes (12th century) are the most distinguished.

During the early middle ages the medicine of north-western Europe was of a very primitive nature. The earliest extant medical manuscript of an Anglo-Saxon people is the Leech-Book of Bald, dating from the time of Alfred the Great. Although it shows traces of Greek influence, it consists merely of a mass of herbal remedies mingled with prayers and spells supposed to be useful for various disorders. As the church was the repository for learning of all kinds, so the practice of medicine came to be a calling followed by the monks in the numerous religious houses which were provided with physic-gardens where simple remedies were produced, and with small hospitals where the sick were treated. The priests, monks, and readers of the monasteries, however well they might know the theory of medicine, could not follow its practice into every corner of daily life, to the battle-field, &c., and in consequence of this detachment a very low class of itinerant lay practitioners came into being, who both earned the contemptuous criticism of the clerics and brought the healing art at times into great disfavour with the public. Before the 9th century, however, there had been growing up in Italy, not far from Naples, the school of Salerno, where philosophy, law, and medicine were taught. It attracted in the succeeding three centuries great numbers of students in pursuit of learning, and of bishops and nobles in search of health. The school was said to have been founded by four doctors of different nationalities, and among its early teachers were Gariopontus, Platearius, Copho, Constantine the African, and Ægidius of Corbeil. The school was at the height of its fame from 1000 to 1200 A.D., during which time Robert of Normandy, son of the

Conqueror, stayed there for the cure of a wound in his arm. To him the medical fraternity dedicated a Latin poem, the 'Regimen Sanitatis,' on the preservation of health, which was much translated and greatly prized. Here, too, women took a prominent part in the study and practice of medicine, and the names of Trotula, Constanza, Sicelgaita, and Stephanía are celebrated for their medical learning. The most important occurrence at Salerno in regard to medicine was the institution by the Emperor Frederick II. in 1224 of examinations for a license to practise. This edict, with the earlier provision of Roger of Sicily in 1140, was the first attempt in Europe to bring the practice of medicine under state control. Soon after this, however, other schools sprang up and displaced Salerno, which was finally closed by an edict of Napoleon in 1811.

Several movements from the 12th century onwards helped to the restoration of medicine. A great humanitarian development, which owed its beginnings largely to Louis IX. and Pope Innocent III., had as one of its principal results the establishment of large charitable hospitals all over Europe. According to Virchow, by the 14th century probably no town of 5000 inhabitants was without its hospital. Combined with this, the rise of the great universities—Paris (1110), Bologna (1113), Oxford (1167), Montpellier (1181), Cambridge (1209), Padua (1222)—did a great deal to render the thorough study of medicine possible, and to free it from the church. Another influence was the translation in the 13th century of many of the Arabic medical works by such men as Albertus Magnus, Arnald of Villanova, and Michael Scot; and the production in the following century of vigorous, original, though often fanciful, medical works, such as those of Gilbert the Englishman, Bernard de Gordon, John of Gaddesden, and St Hildegard of Bingen. In the 15th century the intellectual Renaissance burst into flower in the Italian cities, and the sunshine of princely and municipal favour produced a corresponding growth in medicine. Latin translations from original Greek works, by physicians who were also scholars (such as Thomas Linacre, 1460–1524, in England), produced an accurate acquaintance with the medical knowledge of the ancient world. At Florence, where the Renaissance movement was very strong, association in the same guild of the physicians with artists like Leonardo da Vinci and Michelangelo, who were capable anatomists, greatly fostered the study of human anatomy. The borrowed Arabist medicine was thus displaced by a return to the original classic sources, but the awakened spirit of criticism tended to sweep away all dogmatism and authority in medicine, just as the Reformation did in the religious sphere. The outbreak of the widespread plague in the 14th century, the sweating-sickness of England, and the appearance of syphilis in the 15th century, demonstrated diseases not treated by the ancients, and threw practical medicine upon its own resources. The introduction of firearms in the 14th century performed a similar office for surgery. Paracelsus (1493–1541), who in Germany is regarded as a reforming Luther in medicine, and who elsewhere passes rather as a charlatan and mystic, was a voice crying in the wilderness against the dominance of ancient authority. A saner influence towards the same end was the publication by Vesalius (1543) of his great text-book on human anatomy, which demonstrated the insufficiency and sometimes incorrectness of the Galenic teaching. Padua, in the late 16th century, displaced Paris and Montpellier, as these had superseded Salerno, in being the great medical school to which students flocked from the whole of Europe. Here Vesalius, Fallopius, Cæsalpinus,

Galileo, and Fabricius were teachers. Under the last-named studied William Harvey (1578–1657), who, in 1628, published his little book on the *Motion of the Heart*; this had the effect of showing the value of painstaking research, of demonstrating essential fallacies in old theories, and of opening up entirely new conceptions regarding the bodily functions. The mechanical principles which he introduced were expanded by the work of Borelli, Baglivi, Pitcairne, and others into the Iatro-mechanical system, which regarded all bodily functions as similar to those of a machine. Sylvius (1614–72) developed the theories of the alchemists and of Van Helmont into the Iatro-chemical system, of which the adherents later did good work for medicine in the gradual discovery of the meaning of breathing by Boyle, Mayow, Priestley, and Lavoisier, and of the processes involved in digestion by De Graaf, Réaumur, Beaumont, and the modern Pavlov. A third system to explain bodily activity was introduced by Stahl in the end of the 17th century, and known as 'animism,' or later as 'vitalism.' According to this, the mind acts directly upon bodily functions, so that an intimate knowledge of anatomy or chemistry is presumed to be unnecessary to the physician; this convenient theory had but a short duration, though it has been recently revived by the Christian scientists and psycho-therapists. In the latter half of the 17th century medicine took a new turn in the work of Thomas Sydenham (1624–89), who, as a reactionary against all systems and theories, reintroduced the Hippocratic practice of careful bedside observation and simple treatment in furtherance of nature's efforts towards a cure. He is also celebrated for having given a clear description of gout, the first accounts of scarlet fever and of chorea, and for popularising the use of the recently introduced Peruvian bark against malaria.

The invention of the microscope about 1590, and its application to the structure of the body by Swammerdam, Malpighi, and Leeuwenhoek from about 1660, added greatly to scientific medicine; by these workers the capillary blood-vessels, the blood corpuscles, spermatozoa, and bacteria were discovered, and the structure and functions of the large internal organs were greatly elucidated; a still further and more important set of discoveries on the structure of hair, nerves, &c., and on the minute changes in disease, was made by Henle, Schwann, Müller, and others of the Berlin school when the microscope was still further perfected two hundred years later.

Among the great names of the 18th century the following are specially noteworthy: Hermann Boerhaave (1668–1738) was the leading practitioner of his time, and attendance at a course of his lectures in Leyden was considered for over a quarter of a century the appropriate finish for a liberal medical education. He was a celebrated consultant, visited by patients from all over Europe, though he originated little in the way of medical discovery. Among the pupils of Boerhaave two men are noteworthy as the founders of great medical schools: Gerhard van Swieten, who, as adviser to Maria Theresa, founded the Vienna school; and Alexander Monro, who, becoming professor of Anatomy in his native Edinburgh, was the chief mover in the development of its medical teaching. Albrecht von Haller (1708–77) was another pupil of Boerhaave, and became distinguished both as a physiologist and as a poet; his chief single contribution to physiology was the demonstration that 'irritability' is the special property of all living tissues; while his *Elements of Human Physiology* (1759) marks the beginning of that subject as a modern science. Another great branch of medical science, pathological anatomy, was founded by Morgagni

(1682-1771), who published the results of his life's labours, when seventy-nine years old, in the work, *On the Seats and Causes of Diseases demonstrated by Anatomy*. In this he, for the first time, in a complete and systematic way, brought together the facts of clinical observation and of post-mortem records; his work made an enormous advance in the precision of clinical medicine, and is well worth reading still. Galvani (1737-98) and Volta (1745-1827), by their discovery of electric phenomena in contracting muscles, laid the foundation for later important researches. Joseph Black (1728-99), by discovering 'fixed air' or carbonic acid (1754), and Lavoisier (1743-94), who discovered the true nature of the exchange of gases in the lungs (1775), at last succeeded in explaining the meaning of respiration; while, on the purely medical side, Auenbrugger (1722-1809), by inventing the method of percussing the chest, and Laennec (1781-1826), by describing carefully the sounds heard on auscultation with the stethoscope (1819), rendered accurate diagnosis of lung diseases possible. Cullen (1712-90) was distinguished as a teacher in the Edinburgh school, and for his *Nosology* (1769), in which he classified diseases in the same systematic way as the botanist arranges plants. Thomas Young (1773-1829) is remembered as an all-round genius, specially celebrated for his researches on the subject of optics. Edward Jenner (1749-1823) introduced the practice of vaccination in 1796, a procedure which has been associated with an enormous reduction of the incidence of smallpox, and which formed the model for the later search of Pasteur and others to find similar protection against other diseases. Distinguished practitioners who extended our knowledge of diseases in the 18th century were, in England, Heberden, Fothergill, Lettsom, Huxham, Parry, Withering, Currie, Sir Hans Sloane, Radcliffe, and Mead; in Germany, Werlhof, Stahl, Hoffmann, and Hufeland; in France, Borden; in Italy, Torti and Lancisi; in Switzerland, Tissot and Tronchin; and in America, Benjamin Rush, Shippin, Morgan, &c. These and others first described many of the diseases and symptoms which are commonplaces of to-day.

A great influence on the development of medicine was also exerted by the increasing efficiency of surgery during this century in the hands of such men as Petit, Desault, Chopart in France; Heister and Richter in Germany; Cheselden, Pott, and the brothers John and William Hunter in England. Sanitary science and state medicine may be said to have begun with the *Complete System of Medical Polity* (1777) by Johann Peter Frank (1745-1821), was developed by Sir George Baker (1722-1809), and Sir John Pringle (1707-82), and attained a high position especially in Germany during the next century. The practice of obstetrics had been considerably developed and described in the works of midwives and of Mauriceau (1637-1709) during the 17th century, and the obstetric forceps were invented by Peter Chamberlen about 1670; in the 18th century Van Deventer published (1701) the celebrated text-book which has earned for him the epithet of 'father of modern midwifery'; and in 1752 William Smellie brought out his well-known *Midwifery*; in the 19th century, with the improvements which followed the introduction of anaesthetics and antiseptics, the subject became practically a branch of surgery. Two 'systems' of the late 18th century should be mentioned. John Brown (1735-88) revived the ancient 'methodism' in the theory that all diseases are either 'asthenic,' requiring depressing treatment, or 'asthenic,' requiring stimulation, opium and alcohol being his favourite remedies; by its simplicity this system obtained for a time a great following. Hahnemann (1755-1843) introduced homeopathy

in Germany, a system depending upon the theories that diseases are curable by drugs which produce similar symptoms in the body, that the effect of drugs is increased by giving them in very minute doses, and that most chronic diseases are due to a suppressed irritation. This system has a large following still, especially in America, and it is interesting to observe that some of its tenets are virtually embodied in the modern treatment by 'vaccines.'

The first and second halves of the 19th century form two very distinct epochs in medicine, as they do also in European politics. The first half of the century saw a steady widening of the knowledge regarding disease. In France, Louis (1787-1872) introduced the statistical method into medicine, which has proved a regular and useful mode of investigation in many ways, as, for example, in Louis's hands it showed the valuelessness of indiscriminate blood-letting; French medicine was amplified later by Charcot, Trousseau, Duchenne, Rayer, and others; Laennec has been already mentioned, and his work on interpreting the physical signs of disease in the chest was extended by the French physicians Corvisart, Andral, Piorry, and the Viennese Skoda. The name of Pinel (1745-1826), of the Salpêtrière Hospital at Paris, is celebrated as that of the physician who introduced humane treatment for the insane, and his *Medico-philosophic Treatise on Mental Alienation* (1801) was followed by works on similar lines by Esquirol, Reil, Tuke, and Conolly, and by the general adoption of rational and gentle treatment for this unfortunate class of sufferer.

In Britain an important school arose for half a century at Dublin, where Graves (1796-1853), Stokes (1804-78), and Corrigan (1802-80), were distinguished followers of the French Laennec, and developed greatly the knowledge regarding diseases of the heart and vessels. In London the early years of the 19th century produced a galaxy of clinical observers; Bright (1789-1858), Addison (1793-1860), Hodgkin (1798-1866), and Parkinson (1755-1824), are commemorated in the names of the diseases which they were the first to describe. In Edinburgh, Bell, Christison, Hughes Bennett, and Laycock maintained the fame of that school. Braid, Elliotson, and Esdaile, who published his *Mesmerism in India* in 1846, investigated the phenomena of hypnotic suggestion and trance, placing what had before been a practice of charlatans upon a sound basis. In France, medicine had a strong bias towards physiology in the earlier half of the 19th century. Magendie was the pioneer of experimental physiology, and introduced the practice of trying drugs experimentally on animals (pharmacology); Flourens (1837), by discovering the centre in the medulla governing respiration, began the system of brain localisation, which has since been greatly amplified by Broca, Fritsch, Hitzig, and Ferrier; Claude Bernard (1813-78) discovered the chief functions of the liver and pancreas, and the principle that the blood-supply is regulated by a nervous mechanism, facts of the greatest importance to practical medicine. Beaumont (1825) in America had been the first to study the movements and digestive power of the stomach *in situ*, experimenting for several years on a Canadian trapper whose stomach by a unique accident had been left open through a gunshot wound; and the subject was still further amplified by the discovery of the digestive ferment by Schwann, of the acid by Prout, and of the various conditions under which secretion takes place by Pavlov and his pupils. Still more recently it has been studied through X-ray examination of opaque meals in the living person, thus affording widely increased scope for both medical

and surgical treatment in this very obscure domain. In Germany, medicine during the 19th century had maintained a much closer connection with physiology and pathology than in England, where the traditional clinical attitude of Sydenham has been followed in a greater degree. Much of German medicine has emanated from Johannes Müller (1801-58), through his pupils Schwann, Henle, Kölliker, Virchow, and Helmholtz. Virchow's theory of cellular pathology, according to which life is a property of the cell alone, and all disease is due to aberrations in its activity, caused either by intrinsic or extrinsic causes, displaced the idea of the humours as causes of disease, and dominated medicine from its publication in 1858 almost to the present day. Pasteur had in 1857, while professor of Chemistry at Lille, worked out the causes of fermentation, and later had studied the growth of bacteria (1862), their production of changes in wine (1863), and of disease in silk-worms (1865), and he later discovered the property possessed by weak organisms in producing protection against disease from more virulent varieties (vaccine treatment). Meantime Koch (1843-1910) developed the methods of cultivating and staining bacteria (1877), and subsequently discovered a large number of the bacilli which cause special diseases, including the tubercle bacillus (1882). This laid the foundation for the modern science of bacteriology, which has been still further developed by the study of the poisons or toxins which the bacteria produce, and the antitoxic powers which the body develops to resist them. From this science of 'immunity' many important tests (e.g. the Wassermann reaction in syphilis and the Widal reaction in enteric fever) have been elaborated, as well as several valuable modes of antitoxic treatment, e.g. against diphtheria, tetanus, &c.

The middle of the 19th century was remarkable for several important discoveries. The demonstration of the anæsthetic properties of ether by Morton in 1846, and the introduction of chloroform by Simpson in 1847, chiefly concern surgery, but have produced a profound influence on all branches of medicine. The same may be said of Lister's introduction of antiseptics (1865 onwards). In 1851 Helmholtz invented the ophthalmoscope, by which the deep parts of the eye were for the first time rendered visible during life, and this not only afforded a valuable diagnostic instrument for general medicine, but virtually founded ophthalmology as a special branch. The same may be said regarding the invention of the laryngoscope by Garcia in 1855, and its application to diseases of the throat. In 1851 Pravaz introduced the hypodermic syringe, which has since become indispensable in the administration of active remedies. About 1870 the importance of the thyroid gland was discovered, and from this time the various internal secretions (hormones) and ferments have been studied in relation to many diseases caused by their deficiency in the body fluids, most notably perhaps in the alleviation of diabetes by supplying 'insulin.' Thus a partial return has been made to the old idea of the humours in maintaining health and in producing disease. The action of the heart has been much elucidated by Carl Ludwig (1816-95) and his followers, by means of instruments which take tracings from the movements of the living heart and vessels, the galvanometer which registers the power and transmission of the beats, and other physical methods. The discovery of X-rays by Röntgen in 1893 and the use of these and other forms of radiation by his followers; the developments of chemistry, through which new drugs and new diagnostic methods have been introduced; and the adoption of many procedures from the natural sciences into medical

employment have been the chief distinguishing features of the early 20th century.

In the general improvement of medical treatment during recent years one must not overlook the far-reaching effects produced by the improvement in nursing the sick, which began with the training of deaconesses by the Fliedners (1833), and was extended by Florence Nightingale in England after the Crimean War. The study of tropical diseases, especially those due to lowly organised animal parasites, was a great development of medicine towards the end of the 19th century; this was carried out especially by officers of the British Colonial, Indian Medical, and American Army Services, and has led to the stamping out of malaria and yellow fever in the Panamá Canal zone, Cuba, and West Africa, and to rendering safe these and other regions formerly regarded as the white man's grave. The Great War afforded an opportunity of testing on a large scale many theories and curative methods, such, for example, as protective inoculation against typhoid fever, and had thus indirectly a considerable effect in adding to the expansion and precision of medical knowledge.

For a general review of history of medicine the following may be consulted: Garrison's *History of Medicine* (Philadelphia, 1914); Meunier's *Histoire de la Médecine* (Paris, 1911); Meyer-Steinig and Sudhoff's *Geschichte der Medizin* (Jena, 1921); or the older Baas's *Grundriss der Geschichte der Medizin*, trans. by Handerson (Cincinnati, 1889); Häser's *Grundriss der Geschichte der Medizin* (Jena, 1884); and Puschmann's *Geschichte des medicinischen Unterrichts* (Leip. 1889; trans. by Hare, London, 1891); and for the early period, Withington's *Medical History* (London, 1894). The student who wishes to pursue the history of medicine into minutest detail should consult the larger work of Häser, in 3 vols. (Jena, 1875-79); or Daremberg's *Histoire des Sciences Médicales* (2 vols. Paris, 1870); or Puschmann's *Handbuch der Geschichte der Medizin*, in 3 vols. (Berlin, 1903-5). For a key to the very numerous articles on diseases, see DISEASE, and the list appended to ANATOMY. See also SURGERY, HYGIENE, BACTERIA, GERM THEORY, and the notices of HIPPOCRATES, GALEN, and other great physicians.

Medicine Hat, a manufacturing city of Alberta, on the South Saskatchewan River and Canadian Pacific Railway, has coal-mines and gas-wells; pop. 10,000.

Medick (*Medicago*), a genus of plants of the natural order Leguminosæ, sub-order Papilionaceæ, nearly allied to Clover (q.v.), but distinguished from that and kindred genera by the sickle-shaped or, in most species, spirally-twisted legume. The species, which are very numerous, are mostly annual and perennial herbaceous plants, with leaves of three leaflets like those of clover, and are natives of temperate and warm climates. A number of them are found in Britain, and many more in the south of Europe. They generally afford good green food for cattle, and some of them are cultivated like the clovers for this use, amongst which the most important is the Purple Medick, or Lucerne (q.v., *M. sativa*). Besides this, the Black Medick, Nonsuch, or Lupuline (*M. Lupulina*), is one of the most generally cultivated. It is a common native of Britain, where it is very generally sown mixed with red clover and rye-grass, and is useful where a close turf is desired.

Medimurje, a northern corner of Yugoslavia, between the Drave and the Mur, acquired from Hungary in 1920; area, 300 sq. m.; pop. 100,000.

Medina (Medinat al-Nabi, 'City of the Prophet,' or Medinat Rasuli-llah, 'City of the Apostle of God'), because it was there that Mohammed took refuge after his Hegira or Flight from Mecca in 622, and there that he lived till his death. Formerly called Yathrib, and mentioned by Ptolemy

as Iathrippa, the holiest city of the Mohammedan world after Mecca, and the second capital of the Hejaz in western Arabia, it is situated about 250 miles N. of Mecca, and is accessible by railway (1908) from Damascus. It consists of three principal parts—a town, a fort, and suburbs separated by a wide space (the Munakka, now encroached upon by buildings and the railway). The town is kidney-shaped, within a wall, 35 to 40 feet high, flanked by thirty towers, and enclosing the castle, which renders it the chief stronghold of the Hejaz. Two of its four gates are massive buildings with double towers. The streets are narrow but partly paved. The houses are flat-roofed and double-storied, and are built of stone, brick, and palm-wood. The principal building is the Prophet's Mosque El-Haram ('the Sacred'), supposed to be erected on the spot where Mohammed died, and to enclose his tomb. It is of smaller dimensions than that of Mecca, being a parallelogram, 420 feet long and 340 feet broad, with a spacious central area, surrounded by a peristyle with numerous rows of pillars. The present building is the result of many restorations, of which the last was that of Kait Bey, the Mameluke sultan, in 1481, whose dome and pulpit still stand. The Mausoleum, or Hujra, is an irregular doorless chamber, 50 to 55 feet in extent, situated in the south-east corner of the building. It is surmounted by a large gilt crescent above the 'Green Dome,' springing from a series of globes, and hedged in with a closely-latticed brass railing, in which are small apertures for prayer. The interior is hung with costly curtains embroidered with large gold letters, stating that behind them lie the bodies of the Prophet of God and of the first two khalifs—which curtains, changed whenever worn out, cover a square edifice of black marble, in the midst of which is Mohammed's tomb. Its exact place is indicated by a long pearly rosary suspended from the curtain. The Prophet's body is believed to lie undecayed at full length on the right side, with the right palm supporting the right cheek, the face directed towards Mecca. Close behind him is placed, in the same position, Abu-bekr, and behind him Omar; and Fatima's house is represented by a modern erection hard by. There seems no reason to doubt that the Prophet was buried in the space (originally Ayesha's hut) now enclosed in the mosque; nor is it likely that the grave was ever rifled. That his coffin, said to be covered with a marble slab, and cased with silver, rests suspended in the air is of course an idle Christian fable. It is a meritorious act to perform the pilgrimage to Medina, though there is no fixed season for it. As in Mecca, a great number of ecclesiastical officials are attached in some capacity or other to the Great Mosque; and not only they, but many of the townspeople live to a great extent on the pilgrims' alms and custom. There are few other noteworthy spots in Medina, save the minor mosques of Abu-bekr, Ali, Omar, Bilal, &c. Thirty medressas, or public endowed schools, represent what learning there is left in the city, once famed for its scholars and theologians. In the 7th century Medina was the capital of Islam; it passed under the rule of emirs, sharifs, Turkish pashas, and Wahhâbis. The Turkish garrison, after two and a half years' beleaguering, surrendered to the Hejaz Arabs in 1919. The population, some 40,000 before the Great War, was reduced by deportation and disease to less than 10,000. For authorities see MECCA.

Medina Sidonia, a city of Spain, 25 miles SSE. of Cadiz, on an isolated hill overlooking a wide plain, has the ruins of a castle, the ancestral seat of the dukes of Medina Sidonia, descendants of Guzman the Good, conqueror of Tarifa (1292).

A member of this house commanded the Armada (q.v.). Pop. 14,000, who make pottery.

Medinet-el-Fayûm is the modern capital of Fayûm (q.v.). The Bahr Yûsuf flows through it, and it has bazaars and mosques, including one erected by the Mameluke Sultan Kait Bey in the 15th century, and a population (1917) of 44,400. Near it stood the ancient capital, Crocodilopolis, where the crocodile-god Sobk, or Suchus, was worshipped. Crocodilopolis was renamed Arsinoë, after the queen of Ptolemy Philadelphus, in whose reign the cultivation of the Fayûm was greatly developed. Hawara (see FAYÛM) is also near Medinet.

Meditatio Fugæ. See DEBT.

Mediterranean Sea, so named from lying in the midst between the continents of Europe, Asia, and Africa, is connected with the open ocean only by the narrow Strait of Gibraltar, 9 miles in width at the Pillars of Hercules. Since 1869, however, it has been artificially connected with the Red Sea and Indian Ocean by means of the Suez Canal (q.v.). From its great size the Mediterranean might be ranked with the oceans, but from being so completely cut off it presents distinctly local characters when compared with the great ocean-basins, and is consequently of special interest to the student of physical science. The Mediterranean, in a nearly east and west direction, is about 2200 miles in length from the Strait of Gibraltar to the Syrian coast; its width varies from 500 or 600 miles in some places to less than 100 miles between Sicily and Cape Bon, where it is divided by relatively shallow banks into two distinct hydrographic basins, the eastern one being the larger. It is connected with the Black Sea through the Dardanelles, the Sea of Marmora, and the Bosphorus. The African and Syrian coasts are comparatively even and unindented, the wide gulfs of Gabes and Sidra scarcely presenting an exception; on the other hand, the shores of Europe and Asia Minor are cut up into numerous gulfs and bays, the largest of which is the Adriatic Sea. Various parts of the Mediterranean have been known by special names, such as the Tyrrhenian and Iberian Seas in the western, and the Levant, Ægean, and Ionian Seas in the eastern basin. The principal islands in the western part are Sardinia and Corsica, the Balearic and Lipari Islands, the two latter groups being of volcanic origin. The continental islands of Sicily and Malta are situated on the banks dividing the two basins; Pantellaria, Limosa, and Graham Island (now reduced to a shoal) are, however, volcanic though situated on the same banks. In the eastern regions there are the large islands of Cyprus and Crete, with the Ionian Islands and the islands of the Archipelago. The Mediterranean is frequently subject to earthquakes, and Vesuvius, Stromboli, and Etna are among the most famous of the active volcanoes. The scenery of the shores of this great inland sea is varied, mountain-ranges and high tablelands predominating. Although there is considerable diversity between the climates of Northern Italy and the desert shores of North Africa, still the terrestrial fauna and flora are not markedly distinct in the different regions of the Mediterranean basin, many of the plants and animals being identical on the northern and southern shores, and there is abundant evidence that this similarity was much more pronounced in recent geological times. The countries bordering the Mediterranean have been the cradle of civilisation, Egypt, Crete, Phœnicia, Greece, and Italy having been the homes of knowledge and progress, and at the present time this inland sea is commercially, perhaps, the most important waterway of the world.

The area of the Mediterranean is estimated at about 900,000 sq. m., or, including the Black Sea and Sea of Azov, at 1,053,000 sq. m. The area of land draining into the Mediterranean is estimated at 2,969,350 sq. m., or nearly 3,000,000 sq. m. of the richest country on the earth's surface. The annual amount of rain that falls on this land is estimated by the writer at 1598 cubic miles, and of this amount about 226 cubic miles reach the Mediterranean through the annual discharge of rivers, the principal of which are the Rhone, Po, Danube, Dnieper, Don, and the Nile.

The basin of the Mediterranean commences about 50 miles to the west of Gibraltar, where there is a ridge with a maximum depth of about 200 fathoms. There is a similar depth on the ridge between Sicily and Africa which separates the Mediterranean into two basins: 2040 fathoms is the greatest depth recorded in the western, and 2187 fathoms the greatest in the eastern basin; the mean depth of the whole sea is 768 fathoms. The area of the sea-bottom with a less depth than 100 fathoms is estimated at about one-fourth of the whole area; the area with a depth of from 100 to 1000 fathoms is estimated at 300,000 sq. m., and with a depth of from 1000 to 2000 fathoms at 15,000 sq. m. The bulk of water is estimated at 709,800 cubic miles. The greatest depth in the Black Sea is 1070 fathoms, the average depth being 412 fathoms.

On the whole northerly winds prevail over the Mediterranean, due chiefly to the influence of the anticyclonic region of the North Atlantic, although in the eastern portions the alternate cyclonic and anticyclonic area of northern Asia has a distinct influence on the direction of the winds. The Mediterranean lies wholly between the annual isotherms of 60° F. in the north and 70° in the south. The temperature of the surface waters may occasionally reach 90°, but is usually much less, the mean of the winter months being between 53° and 57°. Generally the temperature of the sea is higher than that of the air, especially in winter, but in some of the summer months the reverse is the case. Whatever the temperature of the surface water may be, at a depth between 100 and 200 fathoms a temperature of 54° to 56° is met with, and this persists without sensible variation to the greatest depth. The temperature of the bottom water in the western basin is about 54°·5, and in the eastern basin a little warmer, 56°·0, these temperatures being fully 20° higher than the temperature of the bottom water of the Atlantic at corresponding depths. From recent observations it would appear that the deep water of the Mediterranean is subject to slight annual variations, dependent on the temperature of the previous winter. The evaporation from the surface of the Mediterranean exceeds both the precipitation and the annual discharge of the rivers flowing into it from the surrounding catchment basin, for we find the specific gravity of its waters (1·02800 to 1·0300) to be greater than that of the Atlantic on the west (1·026 to 1·027), or that of the Black Sea on the east (1·012 to 1·014). There is even an outflow of warm dense Mediterranean water into the Atlantic beneath the lighter Atlantic water which flows in at the surface through the Strait of Gibraltar. There is a similar state of things at the entrance of the Black Sea, where there is an inflow of fresh water from the Black Sea at the surface, and an outflow in the opposite direction of saltier Mediterranean water by an undercurrent. Were it not for the inflow of Atlantic water the Mediterranean would slowly become saltier, and shrink till reduced to two salt lakes like the Dead Sea. The Mediterranean is usually called a tideless sea. At Algiers there is a rise of 3½ inches at springs and half that amount at neaps; at other places the rise and fall

is about 18 inches, and in the Gulf of Gabes the range reaches 5 feet, but the solilunar tides are as a rule completely masked by the rise of level and the surface currents produced by the action of the winds. The deposits now forming in the Mediterranean in deep water are all blue muds, with a yellowish upper layer, containing usually from 10 to 30 per cent. of carbonate of lime, which principally consists of the shells of pelagic Foraminifera. The mineral particles and clayey matter are derived from the disintegration of the neighbouring land. In some of the shallower depths there are glauconitic and more calcareous deposits. The deep-sea dredgings show that life, though present, is much less abundant in deep water than at similar depths in the open ocean, in which respect the Mediterranean agrees with enclosed seas in general. There is an extensive red coral fishery and tunny fishery on some parts of the coasts. The Mediterranean region appears to have been covered by the sea from early geological times, and during Tertiary times must have had much wider communication with the open ocean.

Medium. See SPIRITUALISM.

Medjidie, an Ottoman decoration, instituted in 1852 by the Sultan Abd-ul-Medjid as a reward of merit either civil or military. It was conferred after the Crimean campaign, to a considerable extent, on British officers. The order consists of five classes, and the decoration is a silver sun of seven triple rays, with the device of the crescent and star alternating with the rays.

Medlar (*Mespilus*), a genus of rosaceous trees or shrubs, having a 5-cleft calyx with leafy segments, nearly round petals, a large honey-secreting disc, and 2-5 styles, united together in the flower, but widely separated on the fruit, the upper ends of the bony cells of which are exposed. The Common Medlar (*M.* or *Pyrus germanica*), a small tree, spiny in a wild state, spineless in cultivation, is a native of the south of Europe and of the temperate parts of Asia, but is a doubtful native of Britain, although it is to be seen in hedges and thickets in the southern parts of England. It has lanceolate, undivided leaves, solitary large white flowers at the end of small spurs, and globular or pear-shaped fruit. The medlar is much cultivated in some parts of Europe, and is common in gardens in England, but it does not generally ripen well in Scotland without a wall. It is very austere, but when *blotted*—its tough pulp soft and vinous by incipient decay—it is relished by many.

Medmenham, a village of Buckinghamshire, near the Thames, 3 miles SW. of Marlow. Here stood a Cistercian abbey (12th century); and here, soon after the middle of the 18th century, Sir Francis Dashwood, afterwards Lord le Despencer (1708-81), founded his mock brotherhood of 'Franciscans,' whose motto was the familiar inscription on Rabelais' abbey of Thelema, 'Fay ce que voudras,' and two of whose twelve members were John Wilkes and Paul Whitehead the poet. See a book by the Rev. A. H. Plaisted (1925).

Médoc, a district in the French department of Gironde, famed for the quantity and excellence of the wine it yields, some of the most famous growths of Bordeaux (q.v.), such as Château-Margaux, Château-Lafite, and Château-Latour. The district lies on the left bank of the estuary of the Gironde, being separated from the Landes by low hills, and is 40 miles long by from 5 to 10 wide.

Medusoid. See COELENTERATA, HYDROZOA.

Medway, a river of Kent, rising in three head-streams in Sussex and Surrey, and flowing 70 miles

north-eastward (including 12 miles of estuary), past Tunbridge, Maidstone, Rochester, Chatham, and Sheerness, until it joins the estuary of the Thames. It is tidal and navigable to Maidstone, but large vessels do not ascend above Rochester bridge. See CHATHAM.

Meeanee, or **MIANI**, a village in Sind, India, on the Indus, 6 miles N. of Hyderabad, was the scene of a battle between Sir Charles Napier with 2800 men and a Baluch army, 22,000 strong, on 17th February 1843. The latter were totally routed, and the result was the annexation of Sind.

Meerane, a town of Saxony, 35 miles S. of Leipzig. It developed rapidly through its woollen manufactures and export trade. Pop. (1849) 7345; (1900) 23,851; (1919) 21,927.

Meerkat (*Cynictis penicellata*), a South African carnivore akin to the Ichneumon (q.v.), head and body (covered with reddish fur) a foot and a half long, the bushy, grayish tail a foot. But the name is also given to the Suricate (q.v.) or zenick, to the 'Madagascar cat' or lemur, and even to the Cape ground-squirrel.

Meerscham (*Sepiolite*); a mineral existing in many parts of the world. In Europe it is found chiefly at Hrubcschitz in Moravia, and at Sebastopol and Kaffa in the Crimea; and in Asia Minor it occurs abundantly just below the soil in the alluvial beds of several districts—especially at Eski-shehr. It is also found in Spain and South Carolina. Meerscham, from its having been found on the seashore in some places, in peculiarly rounded snow-white lumps, was ignorantly imagined to be the petrified froth of the sea, which is the meaning of its German name. Its composition is silica, 60.9; magnesia, 26.1; water, 12.0. Almost all the meerscham found is made into tobacco-pipes, in which manufacture the Austrians have been for a long time pre-eminent. Vienna contains many manufactories, in which some very artistic productions are made; and pipes worth 100 guineas, from the beauty of their design, are by no means uncommon. The French pipe-makers also make use of meerscham, and have displayed great taste in their works. When first dug from the earth meerscham is quite soft and soap-like to the touch, and as it lathers with water, and removes grease, it is employed by the Turks as a substitute for soap in washing. Similarly in Algeria it is sometimes used in place of soap at the Moorish baths. The waste in cutting and turning the pipes was formerly thrown away, but it is now reduced to powder, mixed into a paste, and compressed into hard masses, which are carved into inferior pipes.

Meerut, or more correctly **MERATH**, a town, district, and division in the United Provinces of British India. The town lies 40 miles NE. of Delhi, about half-way between the Ganges and the Jumna. Its most important building is the English church, with a fine spire and an excellent organ. There are also several ruins of native edifices. Here in 1857 the great Mutiny broke out (see INDIA). Pop. (1881) 99,565; (1921) 122,609, of whom 45,000 were in the cantonment. The district has an area of 2298 sq. m., pop. 1,500,000; the division, 9181 sq. m., pop. 4,500,000.

Megaceros. See ELK.

Megalichthys (Gr., 'great fish'), a genus of extinct fishes of large size, whose remains are found in Carboniferous and Lower Permian strata both in Europe and America. The large teeth and strong scales suggest predaceous habits. They were 'fringe-finned Ganoids' in the order Crossopterygii, of which *Polypterus* and *Calamoichthys* are the only living representatives.

Megalithic Monuments. See DOLMEN, STANDING STONES, STONE CIRCLES, &c.

Megalonyx, a large fossil edentate of the United States, smaller than the *Megatherium* (q.v.).

Megalopolis, founded by Epaninondas after the battle of Leuctra (371 B.C.), and made the capital of Arcadia, stood in the valley of the Helisson. Plundered and mostly destroyed by the Spartans in 222 B.C., it was the birthplace of Philopœmen and Polybius. Excavations (1890-93) by the British School at Athens revealed a theatre, a temple of Zeus Soter, the Thersileion, or great hall of the Arcadian Assembly, &c.

Megalosaurus (Gr., 'great lizard'), a Theropod Dinosaur, fragments of which have been obtained from Jurassic and Cretaceous strata in Europe, and suggest an animal of large size—perhaps as big as an elephant. It was apparently carnivorous and partly bipedal. See REPTILES.

Megaphone, a device, invented by Edison, by which distant sounds may be heard without any intervening wires. It consists of two funnels six feet long, tapering from two feet six inches in diameter at the mouth to small openings in tubes for the ears. By its means men some miles apart have been able to converse freely.

Megapodidae. See MOUND BIRDS.

Megarís, a small mountainous region of Greece, between Attica and the Isthmus of Corinth. Its people founded colonies at Byzantium (667 B.C.), Chalcedon, and Megara (Hyblæa) in Sicily. The capital was Megara.—For the Megaric school, see EUCLID of Megara; see also THEOGNIS.

Megas'thenes, a Greek ambassador stationed by Seleucus Nicator (306-298 B.C.) at the court of Sandrocottus (q.v.), or Chandra Gupta, in the valley of the Ganges. Here he gathered materials for his work *Indica*, from which Arrian, Strabo, and others borrowed. The fragments that remain have been edited by Schwanebeck (1846) and Müller (1848).

Megatherium (Gr., 'great beast'), a gigantic extinct quadruped of the order Edentata, nearly allied to the sloth, found in the Pleistocene deposits of South and North America, but more particularly in those of the South American pampas. In structure it is very near its modern representative, except that the whole skeleton is modified to suit the requirements of an immense heavy-boned and heavy-bodied animal, fully equal in bulk to the largest species of elephant. The appellation tardigrade, which Cuvier applied to the sloth, cannot be given to the *Megatherium*: its limbs were comparatively short and very strong, and the feet adapted for walking on the ground, approaching in this respect nearer to the allied ant-eaters, but with this peculiarity, that the first toe of each of the hind-feet was furnished with a large and powerful claw, which was probably used as a digger to loosen roots from the soil, and enable the creature the more easily to overturn the trees on the foliage of which it browsed. The enormous development of the bones of the pelvis, the hind-legs, and the tail, gave the animal great power when, seated on its hind-legs and tail, as on a tripod, it raised its fore-legs against the trunk, and applied its force against a tree that had already been weakened by having its roots dug up. The structure of the lower jaw seems to indicate that the snout was prolonged and more or less flexible, and it seems probable that the *Megatherium* was furnished with a prehensile tongue like that of the giraffe, with which it stripped the foliage from the trees. The remains of several allied genera of huge Edentata are associated with the *Megatherium* in the deposits on the pampas. They form the family

Megatheriidae of Owen, which includes *Myloodon*, *Megalonyx*, *Scelidotherium*, &c.—genera which are separated from *Megatherium* chiefly from peculiarities in the dentition. The modern sloth is a

Skeleton of the Megatherium.

native of South America, and the fossil remains of these immense creatures, which represented it in the newer Tertiaries, are found only in the American continent.

Meghna, the estuary of the Ganges (q.v.) and Brahmaputra (q.v.). See Map at CALCUTTA.

Megiddo, an ancient city of Palestine, the site of which is somewhat uncertain, in the plain of Esdraelon. In the battle there Josiah (q.v.) was slain in 609 B.C.

Megilp. See MAGILP.

Megrim. See HEADACHE.

Megrims and **Vertigo** are the terms usually applied when a horse at work reels, and then either stands for a minute dull and stupid, or falls to the ground, lying for a time partially insensible. These attacks come on suddenly, are often periodical, and are most frequent during hot weather and when the animal is drawing up a hill, or exposed during heavy work to the full rays of a hot sun. Liability to megrims constitutes unsoundness, and usually depends upon the circulation through the brain being temporarily disturbed by the presence of tumours, or by weakness of the heart's action. Horses subject to megrims are always dangerous.—For vertigo in the human subject, see VERTIGO.

Mehádia, a village of Transylvania, 15 miles N. of Orsova. Near it are the springs of Herkulesbad (q.v.).

Mehadia, or MAHDIAH, is a North African seaport and health-resort 115 miles SE. of Tunis; pop. 6000.

Mehemet Ali, better MOHAMMED 'ALI, Viceroy of Egypt (1805-49), was an Albanian born at Kavalla in Macedonia in 1769, and was sent to Egypt with a Turkish force in 1799. See EGYPT.

Méhul, ÉTIENNE NICOLAS, operatic composer, was born at Givet, 22d June 1763, studied in Paris, and in 1795 became professor at the Conservatoire. He died 18th October 1817. Among his best-known works are the operas *Une Folie* (1801), *Les Aveugles de Tolède* (1806), and *Joseph* (1807); and the patriotic songs *Chant du Départ*, *Chant de Victoire*, *Chanson de Roland*. See Life by Pougin (1889).

Meilhac, French playwright, born in 1832 in Paris, was trained as an artist and published his

first dramatic work in 1855. He subsequently produced a long series of light comedies—some in conjunction with Halévy. Some are well known through Offenbach's music. His *chef-d'œuvre* is *Frou-Frou* (1869). He died 6th July 1897.

Meinam. See SIAM.

Meinhold, JOHANN WILHELM (1797-1851), a native of the island of Usedom, and Lutheran pastor at Usedom, Krummin, and Rehwinkel, published poems and dramas, but is best known as author of *The Amber Witch* (trans. by Lady Duff Gordon, 1844) and *Sidonia the Sorceress* (trans. 1893).

Meiningen, a town of Thuringia, capital of the former German duchy of Saxe-Meiningen, lies in a narrow valley on the banks of the Werra, 43 miles by rail NW. of Coburg. The ducal castle (1682), the most prominent building, contains libraries, a picture-gallery, collection of coins, &c. There is a fine 'English garden' here. The town has been in great part rebuilt since 1874, when a fire destroyed the old streets. It was an appendage of the see of Würzburg from 1008 to 1542, and from 1583 to 1918 was in the hands of the Saxon ducal family. Pop. (1875) 9521; (1890) 12,029; (1919) 17,094.

Meissen, a town in the former kingdom of Saxony, lies in a beautiful district on the left bank of the Elbe, 14 miles by rail NW. of Dresden. Its chief building is the cathedral (c. 1266-1479), one of the finest Gothic churches in Germany, surmounted by an exquisite spire (263 feet) of open work, and containing many fine brasses. The castle was built in 1471-83, and in 1710 was converted into the porcelain factory over which Böttger presided (see POTTERY). In 1863, the porcelain factory having been removed in 1860 to other premises, the castle was restored, its walls being adorned with frescoes by modern painters. Other manufactures are iron, machinery, jute, and cigars. Here is the celebrated school of St Afra, where Gellert and Lessing were educated. It was founded by Duke Maurice in 1543, and until 1879 occupied the former Afra monastery (built in 1205). Meissen was founded in 928 by Henry I of Germany as a stronghold against the Slavonians, and was long the capital of the margraviate and burgraviat of Meissen, which was subsequently merged in the duchy of Saxony. The town was burned down by the Swedes under Banér in 1637. Pop. (1875) 13,002; (1885) 15,474; (1919) 37,493.

Meissonier, JEAN LOUIS ERNEST, figure-painter, was born at Lyons, 21st February 1813. When he was still a child his father established himself as a druggist in Paris; and the son, having resolved upon art as a profession, studied under Jules Potier and Léon Cogniet. His drawings were praised by Johannot, and about 1833-34 he was employed by Curmer the publisher on designs for the *Royaumont Bible* and other works. He first made a distinct mark in 1833, by his illustrations to *Paul and Virginia* and the *Chaumière Indienne*; many other volumes were enriched by his pencil, and his career as a book-illustrator closes with his spirited designs to the *Contes Rémois* of the Comte de Cheigné. Meanwhile, he had been steadily practising painting. In 1834 he began to contribute to the Salon with a water-colour and an oil-picture, the latter strongly suggestive of the work of the figure-painters of Holland, who have powerfully influenced Meissonier during his whole career. Two years later he exhibited the first of his various groups of 'Chess-players,' and here his accurate precision of draughtsmanship and quietly dramatic truth of attitude and expression first became clearly visible. It was followed by a long series of elaborate and successful genre-pictures, in which, with the most careful and finished—if sometimes

rather hard and unsympathetic—execution, and with the most perfect verisimilitude of costume and local colouring, the artist has depicted the civil and military life of the 17th and 18th centuries, passing—in such works as the ‘Napoléon I.,’ a small single-figure picture which Ruskin sold in 1882 for £6090; the ‘Campagne de France, 1814’ (1864); ‘Solferino’ (1866), now in the Luxembourg Gallery; ‘Cuirassiers or 1805’ (1871); and ‘Friedland or 1807,’ bought by M. Secrétan in 1878 for 400,000 francs—to subjects of genre or history taken from the 19th century. Among the most celebrated of his other military scenes may be named ‘La Rixe’ (1854), purchased by Queen Victoria; and not less fascinating are his simpler groups of students, artists, collectors, &c., such as ‘La Lecture chez Diderot’ (1859), ‘Les Amateurs de Peinture’ (1860), and ‘La Lecture du Manuscrit’ (1867). He also executed some striking portraits, including ‘Dumas fils’ (1877) and ‘M. Victor Lefranc’ (1883). The cartoons of his design for the decoration of the Panthéon—the apotheosis of France—were exhibited in 1889. He etched some dozen plates; and many of his pictures are familiar from engravings.

Meistersinger, or **MASTERSINGERS**, the name given to the poet-musicians of the mediæval German towns. Hans Sachs (q.v.) was the most famous of them. They were organised in guilds, and were a kind of burgher parallel to the Minnesinger (q.v.). The first guild is said to have been founded by Heinrich von Meissen in the early 14th century.

Mekhitar, Mekhitarists. See **MECHITARISTS**.

Mekhong, or **MEKONG** (also called Cambodia), the greatest river of the Siam peninsula, since 1894 mainly controlled by the French (see **SIAM**), is usually identified with the Lan-tsan, which rises in the neighbourhood of Chiamdo in Tibet—its exact sources are not known. It pursues a generally southerly direction to the China Sea, which it enters by several mouths in Cochin-China. This country indeed is formed by its deltaic deposits. The river has a total length of 2800 miles; but is not navigated higher than 14° N. lat. owing to rapids and cliffs which beset its bed in the mountainous regions.

Meklong, a town of Siam, near where the Meklong River runs into the Gulf of Siam. Among its 8000 inhabitants many are Chinese.

Mela, **POMPONIUS**, the first Latin writer who composed a strictly geographical work, was born at Tingentera in the south of Spain, and lived in the time of the Emperor Claudius; nothing else is known concerning him. His work, an unsystematic compendium, is in three books, and is entitled *De Situ Orbis*. The text is greatly corrupted. The *editio princeps* appeared at Milan in 1471; the best modern edition is that by Parthey (Berlin, 1867).

Melaleuca. See **CAJEPUT**.

Melampyrum. See **COW-WHEAT**.

Melancholia. See **INSANITY**.

Melanchthon, **PHILIP**, Luther's fellow-labourer in the Reformation, was born, 16th February 1497, at Bretten, in the Palatinate of the Rhine, now in the republic of Baden. His name was originally Schwarzerd (‘black earth’), of which Melanchthon is a Greek translation. He was educated at the university of Heidelberg, where he took the degree of Bachelor of Philosophy in 1512. In the same year he went to Tübingen, studied theology, took the degree of Doctor, and in 1514 gave lectures on the Aristotelian philosophy and the classics. About this time he published a Greek grammar. On his relative Reuchlin's recommendation he was

appointed in 1518 professor of Greek in Wittenberg. Brought into contact with Luther in that town, he at once became his fellow-worker in the great religious revolution with which Luther's name is identified. Melanchthon brought to his aid an extent of learning that made him to be regarded as another Erasmus, and a gift of lucid exposition and purity of Latin style unrivalled among his contemporaries. The natural sweetness of his temper and the habitual moderation of his views also advantageously tempered Luther's vehemence. In 1521 he published his *Loci Communes Rerum Theologicarum*, the first great Protestant work on dogmatic theology. It passed through more than fifty editions in the course of the author's life. In 1530 he made a most important contribution to the cause of Protestantism, in the Augsburg Confession (q.v.). In 1541 he went to Worms, and soon after to Ratisbon, to conduct the cause of the Protestants in the conferences there. But the influence of the papal legate counteracted all his efforts for a peaceful accommodation, and his own party were much dissatisfied on account of the concessions which he made. After Luther's death, Melanchthon lost in some measure the confidence of some of the Protestants by those concessions to the Catholics which his anxiety for peace led him to make; whilst the zealous Lutherans were no less displeased because of his approximation to the doctrine of Calvin on the Lord's Supper. His consent, conditionally given, to the introduction of the Augsburg Interim (q.v.) in Saxony, in 1549, led to painful controversies, which filled the latter years of his life with disquietude. He died at Wittenberg, 19th April 1560. By his calm wisdom and the reputation of his genius, Melanchthon did much to save the Reformation from those excesses that would have made its progress impossible. In the performance of this task he incurred much opposition from Luther himself, and still more from the enthusiasts who came to the front after Luther's death; but the subsequent religious history of Germany is conclusive proof of the wisdom of his action. By his labours as a scholar and public teacher, Melanchthon ranks with the very highest names in the history of learning and education. Alike by his temper and intellectual interests, he is to be regarded as blending in the happiest proportion the humanist and the reformer. The most complete edition of his works (which comprise a Greek and Latin Grammar, editions of and commentaries on several classics and the Septuagint, biblical commentaries, doctrinal and ethical works, official documents, declarations, dissertations, responses, and a very extensive correspondence with friends and the leading men of the age) is that by Bretschneider and Bindseil in their *Corpus Reformatorum* (28 vols. 1834-60).

See *Lives of Melanchthon* by his friend Camerarius (1566); by Cox (1815), Matthes (Altenb. 1841), Schmidt (Elberf. 1861), Meurer (2d ed. Leip. 1869), Schaff (Lond. 1887), Hartfelder (Berlin, 1889), Bailey Saunders (1897), George Wilson (1898), A. Harnack (1898), Richard (1898), and Ellinger (1902).

Melandryum. See **LYCHNIS**.

Melanesia (Gr. *melas*, ‘black’) is a name given to those Pacific islands near New Guinea which are inhabited by the Papuan race. Dr W. H. R. Rivers's *History of Melanesian Society* (1915) is a very important contribution to cultural anthropology. See **POLYNESIA**.

Melanite. See **GARNETS**.

Melaphyre. See **BASALT**.

Melastomaceæ. A large family of dicotyledonous plants, comprising annual and perennial

herbs, and shrubs and trees, often of huge size. The peculiar venation of the leaves makes, however, all of the 2700 species (171 genera, of which *Tamonea* alone accounts for 550) easily recognisable as belonging to this very natural family. It is chiefly developed in tropical and subtropical America, and tropical Africa and Asia.

Melazgerd. See MANZIKERT.

Melba, DAME NELLIE PORTER, was born at Melbourne, Australia, in 1859, the daughter of a Scottish contractor named Mitchell. Her gifts as a singer were soon evident, but it was only after her marriage to Captain Armstrong in 1882 that she undertook the study of singing under Mme. Marchesi of Paris. In Brussels in 1887 she appeared as Gilda (*Rigolette*), and the following year in London in *Lucia*. Thereafter she sang regularly at Covent Garden and in all the principal capitals of the world, the purity and flexibility of her voice making her a favourite everywhere. She was created D.B.E. in 1918. See *Life* by Hermann Klein (1925).

Melbourne, the capital of the State of Victoria, and the temporary seat of the Australian Government, is situated on the Yarra, a small stream flowing into the northern extremity of Port Phillip. Its site was first seen by a white man (unless the escaped Buckley visited it in 1804) when John Batman, a settler from Tasmania, on 8th June 1835 rowed up the Yarra to the then head of tide-water, and noted that 'this will be the place for a village.' He had two days earlier bought from the aborigines of the district a tract of land reaching from the Dividing Range to the ocean beyond Queenscliff (about 600,000 acres) for an immediate payment of blankets, flour, &c., and a rent in similar kind worth about £320 a year. The first hut, however, was put up not by Batman but on 1st September by another party of settlers under John Fawkner which arrived during Batman's temporary absence in Tasmania. Settlement was at first forbidden by the British Government; but Governor Bourke, seeing that the settlers had no intention of obeying such an order, persuaded the authorities to revoke it, and in 1837 formally laid out the township, which he named after the prime minister of the day. As was usual in those days—and much later—the spot chosen was as far up the river as small sailing-ships could go, in order to minimise the expensive land-transport; and Melbourne (like Brisbane, Rockhampton, and half-a-dozen smaller Australian seaports) has been forced into huge expenditure and numberless shifts to construct under this disadvantage harbour accommodation capable of receiving the larger trading-vessels of recent years. Its difficulties are enhanced by the general shallowness of Port Phillip, across which all vessels must approach it, and the dangers of navigating large vessels through the tide-swept and rock-obstructed passage between the Heads at its southern end. As a seaport, therefore, Melbourne naturally ranks low, and its great prosperity and actual position as the second port in Australasia are due partly to the resources of the State whose capital it is, partly to the keen and persistent enterprise of its citizens. As was the case with Sydney (q.v.), the fact that in it was concentrated the power, both official and financial, which ruled Victoria, led to the concentration on it of all traffic from the inland, and even from the coastal, districts as soon as railways became the chief means of transport. The effect of this on the State at large was not so evil as in the other case; Melbourne was, in any case, the nearest port to the gold-fields which suddenly enriched Victoria, and to the extensive agricultural areas north of the

main range, over which closer settlement first spread itself; and the ports of Geelong, Warrnambool, and Portland, which alone could be seriously injured (no others existing within the State boundaries), had at their back, until quite lately, districts almost wholly pastoral. At the same time, the consequent concentration of population in the capital (in 1921, 50 per cent. of the people of Victoria were within the metropolitan boundaries) has not benefited the State as a whole.

There is a special reason for this concentration. The huge and sudden growth of Melbourne in the fifties of last century was due to an influx of gold-diggers, mostly from the towns of Europe, who, whether they left the diggings rich or poor, made back to town-life and their old trades. The town thus became a manufacturing and financial centre at a time when other colonial capitals were mere collecting and distributing centres; at one time, indeed, Melbourne not only financed the development of inland Queensland, but supplied Sydney with energetic business experts. The establishment in Victoria of a protective fiscal policy further aggrandised its manufacturing centre. Since federation, however, and the adoption of a single fiscal policy for all Australia, the natural advantages of Sydney have re-established their influence, and Melbourne is now the second in importance of the great Australian cities. Its position as temporary federal capital benefits it but little, and will be surrendered without regret.

The city proper lies on the northern bank of the Yarra, covering two spurs of the central plateau and the long, shallow valley between them. Its area is about 7400 acres, and its population (in 1921) 103,269. It is surrounded by 23 suburban municipalities, with populations varying from 6000 to 50,000, of which the most important are, on the north and east, Essendon, Brunswick, Northcote, Collingwood, Fitzroy, Richmond, with Hawthorn across the Yarra; on the south, Prahran, Malvern, Caulfield, St Kilda, Melbourne South (formerly Emerald Hill), and Port Melbourne (formerly Sandridge). Lower down the Yarra, towards the west, lie Williamstown and Footscray. Of these, the chief manufacturing suburbs are the inner ring, Footscray, Fitzroy, Collingwood, Richmond, and South Melbourne; Port Melbourne is the shipping-centre for mail and other large oversea steamers; the outer eastern belt, from Kew to St Kilda, with another belt of less thickly populated municipalities beyond it, is residential in the main. The water-supply and sewerage of the whole area have been managed since 1891 by the Melbourne and Metropolitan Board of Works. The catchment area is in the Plenty Ranges, north and north-east of the city, supplemented by the diversion of a few northward-running streams through tunnels. The sewerage system delivers to a sewage farm at Werribee, 24 miles SW. of the city; there the sewage is filtered over an extensive area, and the resultant liquid discharged into Port Phillip. The municipalities also co-operate with the government and the insurance companies in appointing a Fire Brigades Board, which controls the district within a radius of 10 miles from the centre of Melbourne, the area being slightly enlarged on the south-east.

The glory of Melbourne is Collins Street, probably the finest street in Australasia, which traverses the city area from the main railway station on the west to the government offices on the east; in it are the principal banks, many fine office buildings, and the town-hall, the interior of which was destroyed by fire in 1925. The parliament buildings, at present occupied by the Federal Parliament, are set effectively on a hill facing down Bourke Street, which also contains the general post-office. Among

other noticeable public buildings are the Anglican cathedral in Swanston Street, close to Prince's Bridge, which connects the city with the southern suburbs; the Roman Catholic cathedral, somewhat hidden away behind Parliament House; the Flinders Street station, running along the riverbank from Prince's Bridge to Queen's Bridge; the public library, art gallery and museum, in a single block between Swanston and Exhibition Streets (the reading-room of the library, a domed amphitheatre of reinforced concrete, is a notable combination of comfort and beauty); and the law courts on the western spur.

The university (for which, as an educational institution, see VICTORIA) and its residential colleges lie north of the city, adjacent to a wide stretch of park-lands which include the zoological gardens. South of the Yarra, in an even larger park area, Government House (at present the official residence of the governor-general) stands on a conspicuous hill; near it, on a steep hillside running down to the river, are well-planned and beautiful botanical gardens. Albert Park in South Melbourne, containing a long, shallow lagoon much used for yachting, the Fitzroy and Treasury Gardens behind the government offices on the edge of the city proper, and the huge reserves along the north bank of the Yarra, in which the principal cricket-grounds are situated, also afford wide lung-space and recreation areas for the population of the metropolis. In all these park-lands, and along several of the main roads by which the city is approached, the scheme of decoration by flowerbeds and small plantations is a feature in which Melbourne rightly takes special pride. In few cities has the lack of natural beauty been so admirably compensated by well-devised adornments.

The internal traffic of Greater Melbourne is facilitated by the best suburban railway system in Australia; it was electrified in 1912-23. The tramways (with slight exceptions) were in 1920 put under control of the Metropolitan Tramway Board.

The port of Melbourne is controlled by a Harbour Trust established in 1876 and reconstituted in 1913. Under its control the river-channel has been deepened and shortened; the Victoria dock has been constructed near the city; and piers have been constructed in Hobson's Bay at Port Melbourne and Williamstown. The Williamstown piers are used mainly for export of wheat and wool. Mailsteamers usually berth alongside the Prince's pier at Port Melbourne. A pier on similar lines is under construction at Port Melbourne, a dock (the Appleton) is being excavated west of the Victoria dock, and wharfrage to supplement the existing river and dock wharves is being provided at Newport and Spottiswoode.

The situation of Melbourne renders it of very little use for naval purposes, and the naval depot, formerly established at Williamstown, has been removed to Westernport.

See works named under VICTORIA.

Melbourne, WILLIAM LAMB, VISCOUNT, statesman, was second son of Penistone Lamb, first Viscount Melbourne, and was born in London, 15th March 1779. His education he received at Eton, at Trinity College, Cambridge, and at Glasgow. He entered the House of Commons for Leominster in 1805 as a Whig, a follower of Charles James Fox. But, having become a convert to Canning's views, he accepted in 1827 the chief-secretaryship of Ireland in his government, and continued to hold the post under Lord Goderich and the Duke of Wellington. In 1828 the death of his father transferred him to the Upper House. Returning to his allegiance to the Whigs, in 1830 he took the seals of the Home Office in the government of Earl Grey, and in

July 1834 succeeded his chief as prime-minister, but only remained at the head of affairs until the following November. Peel, however, gave way to Melbourne again in 1835; and he continued in office when Victoria ascended the throne (1837). He succeeded by his uncommon tact in introducing her pleasantly to the various duties of a constitutional monarch. In 1841 he once more passed the seals of office to Sir Robert Peel, and thenceforward took little part in public affairs. He was ineffective as a speaker, but displayed aptitude for affairs and common sense in the ordering of them. His easy cheerful temper and cordial frankness of manner cheered him many friends. Sydney Smith, in his second letter to Archdeacon Singleton, has described his character with an exquisite mixture of sarcasm and compliment. Melbourne died 24th November 1848. He married (1805) a daughter of the Earl of Bessborough, who, under the title of Lady Caroline Lamb (1785-1828), attained some celebrity as a novel-writer, besides notoriety from her relations with Lord Byron. The charge brought against him by the husband in 1836 of seducing the famous Mrs Norton was thrown out by the jury without leaving the box.

See *Memoirs* by Torrens (2 vols. 1878); *Lord Melbourne's Papers*, edited by L. C. Sanders (1889); *The Grenville Memoirs* (1875-85); and *Life* by Dunkley (1890; new ed. 1906); and Queen Victoria's *Letters* (1907).

Melchites, the name given to a body of Christians in Syria, Palestine, and Egypt, who acknowledge the authority of the pope, and accept the doctrines of the Church of Rome, but use the liturgy and ceremonies of the Greek Church. They conduct divine service in Arabic, receive the Lord's Supper in both kinds, and follow the Eastern Calendar. Their priests need not be celibate, but must not marry after ordination. The body numbers perhaps 120,000, and is ruled by a Patriarch of Antioch, Alexandria, and Jerusalem, resident at Damascus (with vicars at Damascus, Alexandria, and Jerusalem), and eleven other bishops. The name Melchites (lit. Royalists, from Syriac *melcho*, 'a king') dates from the 5th century, and was given to those members of the Orthodox Eastern Church who supported the emperors against the Monophysites (q.v.) and Nestorians (see NESTORIUS).

Melchizedek ('king of righteousness'), in the story of Genesis, king of Salem and priest of 'Supreme El.' He met Abram on his return from the victorious expedition against Chedorlaomer, gave him his blessing, and received tithes from him. The ante-legal king-priest stands in Psalm cx. as a figure typical of the vicegerent of Jehovah, and in Hebrews, vii. 3, of the kingly priesthood of Jesus. The chapter in Genesis containing his story stands alone in character in the Pentateuch, and according to most scholars is one of its latest portions. Shalem may be an archaic name for Jerusalem, of whose dynasty or hierarchy Melchizedek, to judge from the Psalm, was the ideal founder. He is said to be 'without father and without mother,' an indication that he was thought to be of mysterious origin.

Melcombe Regis. See WEYMOUTH.

Melagnano, formerly MARIGNANO, a town 12 miles SE. of Milan; pop. 7000. Here Francis I. of France defeated the Swiss in 1515, and the French routed the Austrian rear-guard in 1859.

Melfi, a town of Southern Italy, 30 miles N. of Potenza. The once magnificent cathedral (1155) was ruined by earthquake in 1851. Melfi was the Norman capital of Apulia. Pop. 13,000.

Meliaceæ, a pronouncedly tropical family of dicotyledons, represented in Europe only by the

cultivated *Melia Azederach*, but distributed in 42 genera and about 660 species in the tropics, extending however, with one species to New Zealand, whilst *Toona sinensis* has been found near Peking. The family comprises chiefly trees, many of which supply useful kinds of wood, e.g. mahogany and the so-called cedar-wood for cigar-boxes. Several furnish useful oils and fats.

Melilla, a town, formerly a convict station, on the coast of Spanish Morocco, 8 miles SE. of Cape Tres Forcas, figured in the troubles with the Berbers of the Riff in 1893 and since. It has been held by Spain since 1496. Pop. 42,000.

Melilot (*Melilotus*), a genus of clover-like plants of the Leguminosæ. The Common Melilot (*M. officinalis*), a yellow-flowered annual, common in Britain, has when in flower a peculiar sweet odour like Tonka Bean, which increases in drying. The flowers and seeds are the chief ingredients in flavouring the Schabzieger cheese of the canton of Glarus; as are also those of the Blue Melilot (*Trigonella cœrulea*), a native of the north of Africa, with short racemes of blue flowers, cultivated in Switzerland, Tyrol, and elsewhere. It has the peculiar melilot odour in a high degree. The name Bokhara Clover has been given to one or more species of melilot. The melilots as fodder-crops are useful where the soil is dry or poor. They furnish also Coumarin (q.v.) and fibre.

Melinite, an explosive obtained from Picric Acid (q.v.), itself a powerful explosive, by the admixture apparently of gun-cotton and other substances in proportions not made known. It was introduced for French artillery purposes (for shells) by General Boulanger in 1886. The name, earlier applied to a yellow clay, is from Greek *melinos*, 'quince-yellow' (*mélon*, 'a quince'). Lyddite (q.v.) is similar, but safer.

Meliphagidæ. See HONEY-EATER.

Melkart. See BAAL.

Mellifont Abbey, a ruin standing 4 miles NW. of Drogheda, was the first Cistercian foundation in Ireland. It was founded by St Malachy (see MALACHY) in 1142. In 1539, when it surrendered to Henry VIII.'s commissioners, it had 140 monks. Its remains were excavated during 1884-85.

Melo, the capital of Cerro Largo in Uruguay, on the Tacuari, here crossed by a stone bridge, 'built in 1865 by a Frenchman who was murdered for collecting toll' (Mulhall); pop. 12,000.

Melodeon, an instrument of the type of the Harmonium (q.v.), superseded by the American organ. The name is also applied to the Accordion (q.v.).

Melodrama (Gr. *melos*, 'a song,' and *drama*) strictly denotes a half-musical drama, or that kind of dramatic performance in which declamation is interrupted or accompanied by instrumental music. The name, however, which was first applied to the *opera* by its inventor, Ottavio Rinuccini, has come to designate a romantic play, depending mainly on sensational incidents, thrilling situations, a dénouement in accordance with the demands of poetic justice; and there are other appeals, more or less crude, to sentiment. Great sums are spent in the staging of such pieces, and the costumes, scenery, and mechanical effects are often very striking. The expression 'transpontine drama' refers to a time when such plays were identified with houses on the Surrey side of the Thames; later homes of melodrama in London have been Drury Lane, the Adelphi, the Lyceum, &c.

Melon (*Cucumis Melo*), a plant of the same genus with the Cucumber (q.v.), much cultivated for its fruit, which is sweet, with a delicious though

peculiar flavour and smell. The melon is an annual, with trailing or climbing stems, lateral tendrils, rounded angular leaves, small, yellow, monœcious flowers, and large round or somewhat ovate fruit. It is supposed to be a native of the subtropical parts of Asia, although it has never been discovered in a wild state. Its English name was originally *Musk Melon*. The varieties in cultivation are very numerous, some of them distinguished by a thick and warty rind, some by a rind cracked in a net-like manner, some by ribs and furrows, some by a perfectly smooth and thin rind; they differ also in the colour of the *flesh* of the fruit, which is green, red, yellow, &c.; and in the size of the fruit, which varies from 3 or 4 inches to a foot or more in diameter. The melon is eaten either by itself or with sugar, and sometimes with pepper or ginger. Its cultivation in hotbeds and in specially constructed hothouses is extensively carried on in all parts of Britain, and very great care is bestowed on it. A loamy soil is best suited to it. The *setting* of the fruit by dusting the female flower with the pollen of the male flower is constantly practised by gardeners. Warmth and bright sunshine are requisite to the production of fruit of good quality.—The Water Melon or Citrul (*Citrullus vulgaris*), rarely cultivated in Britain, is highly esteemed and much cultivated in almost all warm countries. It is a native of the warm parts of the Old World. It has deeply lobed and gashed leaves, and a large round fruit with smooth dark-green spotted rind, and pink or white flesh, less sweet than the melon, but much more juicy or watery, and therefore much prized in many warm countries. In the United States it is only the water melon that is ever called simply melon; for the other the old English name is retained where 'cantaloupe' is not used. In South Carolina the water melon has reached 45 lb.—South Africa has a variety of Water Melon (var. *Caffrorum*) very valuable to the inhabitants.—The Chate (*Cucumis Melo*, var. *Chate*) is a native of Egypt and Arabia.—The Kaukoor (another variety) is a native of India, and much cultivated in some parts of that country; it has oval fruit, smooth, variegated with different shades of yellow, and about 6 inches long, with much the flavour of the melon. The fruit will keep for several months, and is much used both raw and in curries. The half-grown fruit is pickled. The seeds contain much farina and oil, and are ground into meal; the oil is also expressed, and used both for food and in lamps. The seeds of others of this genus may be used in the same way; and they are said to be useful as a diuretic medicine.

Melos (Ital. *Milo*), a Greek island, the most south-westerly of the Cyclades, 13 miles long by 8 broad, with 5000 inhabitants. The island is volcanic, and produces sulphur, salt, pumice-stone, stucco, millstones, and a little oil and wine. Amongst the ruins of the ancient city of Melos, and near its theatre, was found the priceless antique, the Venus de Milo, now one of the chiefest treasures of the Louvre (see VENUS). A Bronze Age town at Phylakopi, on the E. coast, has been excavated since 1896. See Sir Cecil Smith and others, *Phylakopi* (1904).

Melpom'ene ('the singing one'), one of the nine Muses, the representative of Tragedy.

Melrose, a pleasant little town of Roxburghshire, on the south bank of the Tweed, and at the north base of the triple Eildons (q.v.), 37 miles SSE. of Edinburgh by rail. At Old Melrose, 2½ miles further east, was founded about 635 the Columban monastery, of which St Cuthbert (q.v.) became a monk. It was burned by Kenneth MacAlpine in 839, and had been quite deserted

for upwards of fifty years, when in 1136 the great Cistercian abbey of Melrose itself was founded by David I. In the 13th century the possessions of the abbey increased, and finer buildings took the place of the early structures. A new chapter-house was erected about 1240. In 1322, and again in 1385, the abbey was plundered by English invaders, and during the 15th century it was slowly rebuilt on a scale of increased magnificence; work was still in progress upon it as late as 1505. The church was damaged and its monuments defaced by the English in 1544, while in the following year the monastery was burnt in Hertford's invasion. Neglect and the stripping of the lead from the roofs completed its destruction. In 1618 the monks' choir was re-roofed and occupied by the Reformed Church as a parish kirk. The abbey was beyond doubt the most beautiful structure of which Scotland could boast in the middle ages. What now remains is the ruined conventual church, 215 feet long by 116 across the transepts. Excavations have further revealed the foundations of the buildings surrounding the cloister: the 13th-century chapter-house, the refectory with its circular lavatory, and the cellarer's range with an enclosed courtyard on the west. The carvings and traceries, hewn in a stone of singular excellence, are scarcely surpassed by any in England. Melrose shines in Scott's pages with a splendour its published history fails to sustain. The second abbot, St Waltheof, the royal founder's stepson; Alexander II. and Johanna, his queen; the heart

Melrose Abbey.

of Robert Bruce; the good Sir James, the Knight of Liddesdale, the hero of Otterburn, and others of the Douglas line; the 'wondrous Michael Scott'; and Sir David Brewster—all these are buried here; else, the annals of Melrose have little to record. A burgh of barony since 1609, a police burgh since 1895, the town possesses a market-cross (1642), a suspension foot-bridge over the Tweed (1826), a hydropathic (1871), and half-a-dozen hotels, it being a great tourist centre, as well for its abbey as from the vicinity of Abbotsford, Dryburgh, &c. Pop. (1841) 893; (1921) 2155. At Newstead, 1 mile E., a Roman fort, Trimontium, has yielded finds of supreme importance.

The *Chronica de Mailros*, 731–1275, and the *Liber S. Marie de Melros* were printed by the Bannatyne Club, 1837; and *Selections from the Records of the Regality of Melrose*, ed. C. S. Romanes, by the Scottish History Society, 1914–17. See Scott's *Abbot and Lay of the Last Minstrel*; works by Wade (1861) and Pinches (1879); and for Trimontium, Curle's *Roman Frontier Post* (1911).

Melting-point. The following are some of the most important melting-points, which may also be regarded as the freezing-points of the corresponding liquids:

Melting-points beyond about 900° or 1000° F. are merely approximate and relative.

Melton-Mowbray, a town of Leicestershire, in the centre of a great hunting district, is seated on the river Eye near its junction with the Wreak, 15 miles NE. of Leicester, and 104 NNW. of London. It has a fine cruciform church, mainly Early English, and is famous for its manufactures of pork pies and Stilton cheese, chiefly for retail in the London, Manchester, and Leeds markets. Near the town in February 1644 a severe engagement took place between parties of royalist and parliamentary troops, resulting in the defeat of the latter; and amongst its natives have been Archbishop de Melton, who lies buried in the church, and 'Orator' Henley. Pop. 9000.

Melun, the capital of the French department of Seine-et-Marne, on the Seine, near the Forest of Fontainebleau, 28 miles SE. of Paris. It has two interesting churches, and manufactures of leather, pottery, &c. Melun, the *Melodrumum* of Cæsar, fell into the hands of the English after a six months' siege in 1420, and was held by them for ten years. Pop. 15,000.

Melusine, or MELUSINA, the name of a fairy lady, who figures prominently in the celebrated mediæval French romance so called, the *motif* of which is similar to that of the legend of Eros (Cupid) and Psyche, is of far-reaching antiquity, and has many parallels and analogues in the legends and popular fictions of most countries, Asiatic as well as European. Briefly stated, Melusine consents to marry a knight called Raymondin, or Raymond, on the condition that he should never see her on a certain day every week. She bears him eight sons, the warlike exploits of seven of whom occupy the greater portion of this entertaining romance. At length Raymond is induced by his brother to break his promise, and on the usual day of Melusine's seclusion he discovers her in a bath, the lower part of her body being like a great serpent. Soon after this Raymond, enraged at the cruelty of one of his sons, upbraids the innocent Melusine as 'a false serpent,' whose offspring could never come to any permanent good. Melusine

forgives him, but her doom cannot be averted, and, after a touching scene, she takes her flight through the window in the likeness of a monstrous dragon; and in this form she afterwards appeared hovering near the castle of Lusignan—erected by her own fairy power for her beloved lord Raymond—when ever one of her descendants was about to die, thus acting the part of the Irish *Banshee*.

In the myth of Cupid and Psyche the mortal maiden is not to behold her celestial spouse; but, invited by her envious sisters, she takes a lighted lamp to look upon him one night as he lies asleep, and, in her agitation at beholding his marvellous beauty, a drop of oil from the lamp falls on him, whereupon he and the splendid palace vanish, and Psyche finds herself on a desolate heath. She is reunited to him, however, after performing a number of seemingly impossible tasks by order of her vindictive mother-in-law, Venus. This myth has deeply penetrated European folklore.

One of the oldest legends of this class is the Hindu myth of Urvashi and Pururavas, the condition which the celestial nymph imposes on her husband being that she is not to see him naked.

Such conditions occur frequently in the fairy tales of almost every people (see also LOHENGRIN); and it may be added that tales of forbidden chambers, familiar to readers of the *Arabian Nights*, of which many examples are current in Europe, are closely allied to legends of the Urvashi and Pururavas, Eros and Psyche, and Melusina cycle.

See Max-Müller's *Chips from a German Workshop*, vol. ii.; Baring-Gould's *Curious Myths of the Middle Ages*; Cox's *Mythology of the Aryan Nations* (1870); Grimm's *Teutonic Mythology* (trans. Stallybrass); Clouston's *Popular Tales and Fictions* (1887), and *Group of Eastern Romances and Stories* (1889); Baudot's *Les princesses Yolande et les ducs de Bar*, pt. i. (1900); the old English version of John of Arras's 14th-century French prose romance of *Melusine*, from a unique MS. of the 15th century (E.E.T.S. 1895, with appendix on the Cupid and Psyche and Melusina cycle of legends); and that of La Coudrette's verse romance (E.E.T.S. 1899).

Melville, the name of an island, a sound, and a peninsula in the polar regions of North America. The *island* is crossed by 75° N. lat. and 110° W. long., and is separated on the west by Fitzwilliam Strait from Prince Patrick Island. Greatest length, 200 miles; greatest breadth, 130 miles. In 1819 Parry, who gave the island its name, passed the winter here with his crews. Stefánsson found coal. The *sound*, about 250 miles long by 200 broad, extends south-east of the island, and communicates with the Arctic Ocean on the west by Banks Strait, and with Baffin Bay on the east by Barrow Strait and Lancaster Sound. The *peninsula* projects from the continent at its north-eastern corner, and has on the N. the Fury and Hecla Strait, and on the E. Fox Channel. It is 250 miles in length by about 100 in average breadth.—Another Melville Island lies across the entrance to Van Diemen Gulf off the shore of the Northern Territory of Australia. Area, 143 sq. m. It is hilly and covered with vegetation. The earliest British settlement on this coast was made here in 1824.

Melville, ANDREW, a champion of Scottish Presbyterianism, was born 1st August 1545 at Baldowie, near Montrose. He was educated at Montrose, at St Andrews, where he earned a reputation for his learning, and at Paris. In his twenty-first year he was chosen regent in the college of St Marceon, Poitiers, and in 1568, through the influence of Beza, was appointed professor of Humanity in the Academy, Geneva. On his return to Scotland (1574) he was appointed Principal of the college of Glasgow, where he did the highest service to the cause of learning. He had a very important share in drawing up that charter of the

Presbyterian polity, the Second Book of Discipline (see DISCIPLINE). In 1580 Melville was chosen Principal of St Mary's College, St Andrews. Here, 'besides giving lectures on theology, he taught the Hebrew, Chaldee, Syriac, and Rabbinical languages.' In 1582 he preached the opening sermon before the General Assembly and boldly inveighed against absolute authority. Two years later Melville was summoned before the Privy-council on account of a sermon preached at St Andrews; and to escape imprisonment he removed to London; but on the downfall of Arran (1585) he returned, and in 1586 resumed his office at St Andrews. He was repeatedly elected moderator of the General Assembly, and was made rector of St Andrews in 1590. At Cupar in 1596 Melville headed a deputation to 'remonstrate' with the king; and when James reminded the zealous remonstrant that he was *his* vassal, 'Sirrah!' retorted Melville, 'ye are God's silly vassal.' In 1606 Melville, with seven other ministers, was called to England to confer with the king. Having ridiculed the service in the Chapel Royal in a Latin epigram, he was summoned before the English Privy-council, when he broke out into a torrent of invective; thereupon he was sent to the Tower, where he remained for more than four years. In 1611 he was released through the Duke of Bouillon, who wanted his services as a professor in his university at Sedan. Melville, now in his sixty-sixth year, would fain have returned to Scotland, but James would not listen to his request. He died about 1622, but neither the date of his death nor the events of his last years are ascertained. See *Lives* by M'Crie (2 vols. 1819) and W. Morison (1899).

Melville, HERMAN, American author, was born in New York, 1st August 1819. His higher education was limited. Having farmed for a time, in 1837 he shipped before the mast to Liverpool, and returning to the United States was a school teacher from 1837 to 1840. In 1841 he sailed to the Pacific on a whaler, but at Nukahiva, in the Marquesas, he and a companion deserted on account of ill-treatment by their captain, and were held in 'indulgent captivity' by the savages of the Typee (Taipi) valley. At the end of four months Melville was rescued by an Australian whaler—his companion had earlier escaped—and after various wanderings returned in 1844 to the United States to devote himself to literature, though from 1866 to 1885 he held a post in the customs-house of New York. In 1846 he published *Typee*, his first work, a spirited narrative of his chances in the Marquesas, and in 1847 *Omoo* (Polynesian for 'rover'), a continuation of his adventures in Oceania; both these autobiographical romances enjoyed in their day a great vogue. *Mardi*, of 1849, was a much inferior work. *Redburn*, also of 1849, was based on the author's early voyage to Liverpool; while *White Jacket* (1850), an account of life on a man-of-war, helped in the abolition of flogging in the United States navy. In 1851 appeared *Moby Dick*, a tale of whaling, and Melville's best and most memorable work; here is a strange mingling of speculation and experience, and the story has been ranked among the greatest sea romances of the world. Thereafter, however, Melville's powers showed remarkable decline. *Pierre* (1852), *Israel Potter* (1855), *The Piazza Tales* (1856), *The Confidence Man* (1857), are no more than disappointments of earlier promise; while the verses to which in his later years he solely devoted himself are only rarely happy. He died at New York, 28th September 1891. There is an edition of Melville's collected works (London, 16 vols. 1922-24); and see a *Life* by Weaver (1922), and *Some Personal Letters of Herman Melville, and a bibliography* (1923) by Minnigerode.

Melville, JAMES (1556-1614), nephew of Andrew Melville, was born near Montrose. Educated at St Andrews, he became successively regent or tutor in the college of Glasgow, professor of Oriental Languages in the university of St Andrews, and minister in 1586 of Kilrenny, Fife, whence he was ejected in 1606. He is mainly remembered for his so-called *Diary*, extending from 1556 to 1601. Though Melville here sees all persons and events from his own point of view as a Presbyterian minister, his record is, nevertheless, of real interest and importance. There are editions in the Bannatyne Club (1829) and Wodrow Society (1842).

Melville, SIR JAMES, of Halhill, born in 1535, was sent as page of honour to the young Queen Mary in France, and subsequently undertook numerous missions to the court of England and of the Elector Palatine. He died 1st November 1617, leaving interesting Memoirs, of which the standard edition is that of the Bannatyne Club (1827).

Melville, VISCOUNT. See DUNDAS.

Melville, WHYTE. See WHYTE-MELVILLE.

Membrane, in Anatomy, is a term applied to designate those textures of the animal body which are arranged in the form of laminae, and cover organs, or line the interior of cavities, or take part in the formation of the walls of canals or tubes. The structure and special uses of some of the most important of the animal membranes are noticed in separate articles, such as the Mucous Membrane (see DIGESTION), Serous Membranes (q.v.), &c.; and the membranes in which the fœtus is enclosed are described in the article Placenta.

Memel, or KLAIPEDA, a Prussian seaport and fortress detached from Germany by the Treaty of Versailles (1919) along with the country north of the Niemen and its Skierwieth mouth and a portion of the Kurische Nehrung, and given conditionally to Lithuania in 1923, lies at the northern extremity of the Kurisches Haff, at its opening into the Baltic, 70 miles NNE. of Danzig. It has a large harbour, and exports timber, flax and linseed, manure, grain. The imports include the exports in transit, herrings for Lithuania, and textiles, provisions, and wine and spirits for local use. The town possesses manufactories of brandy, cellulose, soap, and chemicals, sawmills, iron-foundries, breweries, and ship-building-yards. There is a good school of navigation. Pop. 40,000. Memel was founded in 1252 by the Livonian order, who gave it to the Teutonic Knights, by whom it was fortified in 1404. It suffered severely in the Lithuanian wars (13th to 15th centuries). Here in 1807 Frederick-William III. of Prussia took refuge, and a treaty with England was signed. Having been almost wholly destroyed by fire in 1854, it was rebuilt in modern style. For the river Memel, see NIEMEN.

Memlinc, or less correctly MEMLING, HANS, Flemish painter, was born of Dutch parents at Mainz in the first half of the 15th century, and died at Bruges, where most of his life was spent, on 11th August 1494. His painting gained him a wide reputation, extending even to England and Italy. His principal works are religious, such as 'The Last Judgment' (at Danzig), 'Seven Sorrows and Seven Joys of the Virgin', 'Marriage of St Catharine', 'Adoration', several Madonnas, and the fourteen small paintings that adorn the shrine containing St Ursula's relics at Bruges; but he painted also portraits, as of Sir John Donne, of Burgomaster Moreel, and of Moreel's daughter. See Lives by Weale (1871 and 1901), Michiels (French, 1883), Kaemmerer (German, 1899).

Memmingen, an old town of Bavaria, 33 miles SSE. of Ulm, played a prominent part in the

religious wars of the 16th century. Here Moreau defeated the Austrians under Kray, 9th and 10th May 1800. Linen, cloth, &c., are manufactured. Pop. 13,000.

Memnon, a hero of Greek mythology, son of Tithonus and Eös (the Dawn), who led to Troy a host of Ethiopians to aid his step-uncle Priam after the death of Hector, slew Antilochus, Nestor's son, in single combat, and was himself slain by Achilles. Various legends are told of his supposed rule at Susa, where he was said to have built the acropolis, and of his vassalage to the Assyrian Tentamus. His corpse was removed from the battlefield by Eös, whose early tears for her son are by mortals called dewdrops, and his followers the Memnonides were turned into birds. Memnon is chiefly a post-Homeric hero, and attained his greatest celebrity in very late times, when the Greeks discovered the two famous colossal statues of Amenoph III. standing in front of his now vanished temple on the left bank of the Nile at Thebes, and regardless of history dubbed the eastern one Memnon. It is an imposing throned figure, originally about 60 feet high, carved in breccia, but broken in ancient times and repaired with sandstone blocks. Its special peculiarity, which procured it the name of the 'Vocal Memnon' and the honour of forming one of the seven wonders of the world, was the property of emitting a metallic sound, like the snapping of a chord, especially about sunrise, whence the imaginative Greeks concluded that it was the voice of Memnon hailing his newly-risen mother the Dawn. Considerable difference of opinion has prevailed as to the real cause of this phenomenon, which has been variously ascribed to the artifice of the priests, who struck the sonorous stone of which the statue is composed, to the passage of light draughts of air through the cracks, and to the sudden expansion of aqueous particles under the influence of the sun's rays. This remarkable quality of the statue is first mentioned by Strabo, who visited it in company of Ælius Gallus about 18 B.C.; and upwards of a hundred inscriptions of Greek and Roman visitors incised upon its legs record the visits of ancient travellers to hearken to Memnon when he

Softly sings beneath the Libyan hills,
Where spreading Nile parts hundred-gated Thebes,

from the ninth year of Nero, 63 A.D., to the reign of the Emperor Severus, when it became silent. Amongst visitors whose names are recorded are the Emperor Hadrian and his wife Sabina. Septimius Severus also visited the statue, and is believed to have restored it in its present shape; for Juvenal mentions it as broken in half (*dimidio magicæ resonant ubi Memnone chordæ*), and no notice of it occurs under the Pharaohs or Ptolemies (see *Edinburgh Review*, July 1886).—The name of Memnoneum was given to the sepulchral quarter of Thebes, and there were Memnonea at Abydos.—Besides the mythical Memnon two historical personages of this name are known—one a Rhodian commander of the mercenaries of Artabazus in the war against Artaxerxes-Ochus, who subsequently fled to Macedon, and afterwards entering the Persian service defended Persia against Alexander (336 B.C.), and finally died at the siege of Mitylene (333 B.C.); the other a Greek historian, who wrote a history of Heracleia Pontica in 16 books, which have been epitomised by Photius.

Memoirs. See BIOGRAPHY.

Memory. See MNEMONICS, PSYCHOLOGY.

Memory, DISEASES OF. Memory is the power of reproducing mental or sensory images. We owe to the writings of such men as Bergson and Freud our knowledge of the fact that forgetting is an active and not a passive process in ordinary mental life,

for consciousness rigidly suppresses all images that do not bear upon the actual interest of the present. Yet such images may be stored in the subconscious, and may in certain circumstances be resuscitated. Memory is affected in most kinds of mental derangement, in some forms of cerebral disease, and in certain bodily illnesses, but is in a most signal manner obliterated or enfeebled in *Dementia*. There are, however, examples of memory surviving all other faculties, and preserving a clear and extensive notion of long and complicated series of events amid general darkness and ruin of mind. There are, however, special affections of the faculty. It may be suspended while the intelligence remains intact. Periods of personal or general history may elude the grasp, and even that continuity of impressions which goes far to constitute the feeling of personal identity is broken up, and a duality or multiplicity of experiences may appear to be conjoined. The converse of this may happen, and impressions that had completely faded away may, under excitement or cerebral disease, return. There are, besides, states in which this power is partially affected, as in the instances where the numbers 5 and 7 were lost, and where a highly-educated man could not retain any conception of the letter F; secondly, where it is perverted, recalling images inappropriately and in an erroneous sequence of order or time, and different from what are desired; and thirdly, where, while the written or printed signs of ideas can be used, the oral or articulate signs are forgotten. Such examples of diseased memory are now classified as *amnesia*, simple loss of memory; *amnesic aphasia*, loss of memory of spoken words (see *APHASIA*); and *amnesic agraphia*, loss of memory of written words. Most of these special deviations from health depend upon morbid changes in limited portions of the brain. The discovery of this fact by Broca was the first of the brilliant discoveries as to the localisation of function in the brain cortex. See Ribot, *Les Maladies de la Mémoire* (1881); Bergson, *Matière et Mémoire*; Freud, *The Psychopathology of Everyday Life*.

Memphis, a celebrated Egyptian city, situated at the apex of the Delta, or Lower Egypt, the ancient capital of the country, called by the Egyptians *Men nefer*, or 'the Good Station,' by the Hebrews *Moph*, and by the Arabs *Memf*. It was founded by Menes, the first monarch of the 1st dynasty, who, according to Herodotus, changed the bed of the Nile, and made an embankment 100 stadia above Memphis to protect the new city against inundations, the remains of which still exist about 14 miles above Mitrahenny, the centre of old Memphis, and the site of the temple of Ptah. Menes fortified the city, and laid the foundations of the temple. The site was well chosen; protected alike by the Libyan and Arabian chains of mountains against the river and the incursions of the sand, defending the approach of the country from the incursions of Asiatic nomads, and communicating with the Red Sea and the Mediterranean. The city, which at one time had a circumference of 150 stadia, was composed of two portions—one built of crude bricks, the other, on which was the citadel, of calcareous stone. The palace, built by Menes, was enlarged by his son Athothis, and was always inhabited either by a monarch or by his viceroy. After the 6th dynasty the city declined in importance, and was apparently held by the Hyksos after the 13th and before the 18th (1500 B.C.). At this period Memphis was ruled by a viceroy, a prince of the blood, and still remained a religious capital. It rose again to great importance under the Saïte monarchs, about 600 B.C., who restored it; and it was conquered by Senacherib. Its temples were magnificent, and comprised the Iseum, a large temple of Isis, completed

by Amasis II. just prior to Cambyzes (525 B.C.); a temple dedicated to Proteus, in the foreign quarter; the temple of the Apis, having a peristyle and court ornamented with figures, opposite the south propyleum of the temple of Ptah, where the sacred bull resided; the Serapeum, or temple of Serapis, discovered by M. Mariette; the Nilotometer; a temple of Ra; and the shrine of the Cabiri. Here were the statues of Rameses II., one of which is known as 'the fallen colossus,' at Mitrahenny. Still more remarkable was the great necropolis of the city, in the centre of which towered the pyramids (see *PYRAMIDS*). During the attempts of the native rulers to throw off the Persian rule, Memphis was an important strategic point. Ochus inflicted severe injury on this town, having plundered the temples and thrown down the walls after he had driven out Nectanebes. Alexander the Great here worshipped the Apis, and his corpse was brought to this city by Ptolemy before it was finally transferred to Alexandria. The first Ptolemies were crowned in the Serapeum. Ptolemy VIII. destroyed the city, and it fell with the rest of Egypt under the Roman rule, and afterwards was conquered by 'Amr ibn el-Asi (640 A.D.). Its ruins, which served as quarries for later buildings, were large and important in the 13th century, when they were seen by Abd-ul-Latif; but little is now to be seen beyond deeply-buried walls. See works cited at *EGYPT*.

Memphis, a city and port of entry of Tennessee, stands on a high bluff on the east bank of the Mississippi River, 826 miles above New Orleans, and 230 miles by rail WSW. of Nashville. The river to this point is navigable for the largest sea-going vessels, and the place is important as a railway centre; the trade of Memphis is accordingly very large. It is a handsome town, with wide, regular streets, and great warehouses bordering the esplanade that extends along the bluff. The public buildings include a custom-house, cotton exchange, a large hospital, a Roman Catholic college, and numerous churches. Memphis is one of the first cotton marts in the United States, and has numerous manufactories. The city was visited by fearful epidemics of yellow fever in 1878 and 1879, and since then its drainage has been reconstructed. A great steel cantilever railway bridge across the Mississippi was opened in 1892; it has five spans, and a total length of 1886 feet. Pop. (1850) 8841; (1870) 40,226; (1880) 33,592; (1900) 102,320; (1920) 162,351.

Menado. See *CELEBES*.

Ménage, GILLES, a French writer, born at Angers in 1613, gave up the bar for the church, but chiefly spent his time in literary pursuits. He founded, in opposition to the Academy, a salon, the Mercuriales, which gained him a European reputation, and as the pedant Vadius in *Les Femmes Savantes* the ridicule of Molière. His *Dictionnaire Étymologique de la Langue Française* (1650; best ed. by Jault, 2 vols. 1750) and his *Origini della Lingua Italiana* (1669) are erudite works, but contain many fanciful etymologies. He died in 1692. See *Life* by Baret (Paris, 1859).

Menai Strait, a channel between Carnarvonshire and the island of Anglesey, running east-north-east from its southern extremity to Bangor, a distance of 14 miles, where it widens out into Beaumaris Bay. Its width varies from about 200 yards to 2 miles, whilst the scenery on both sides is very picturesque. The navigation is hazardous, but for the sake of expedition vessels under 100 tons, and occasionally some of larger size, pass through the strait. At its entrance the tides sometimes rise to a height of 30 feet; ordinary neap-tides, however, do not rise more than from 12 to

15½ feet. Since 1825 access to Anglesey has been afforded by a suspension bridge, and since 1850 by the Britannia Bridge. See **BRIDGE**.

Menam, the principal river of Siam (q.v.).

Menander, the most famous Greek poet of the New Comedy, was born at Athens in 342 B.C., and was drowned at the Piræus in 291. He was the friend, if not the pupil, of Theophrastus, and the intimate of Epicurus. He wrote over a hundred comedies, of which, however, only eight gained the prize, his work, it would seem, appealing more to cultivated than to popular audiences; but posthumously he enjoyed an enormous reputation in antiquity. He was praised by Plutarch and Quintilian, and was frequently adapted and imitated, most notably by Terence and Plautus. Many of his moral maxims have become proverbial, as 'Whom the gods love die young,' 'Évil communications corrupt good manners' (from the *Thais*, quoted in 1 Cor. xv. 33). His work survives only in fragments, mostly discovered since the end of the 19th century. In 1897 Professor Nicole published 87 lines, newly recovered, of the *Georgos* (see the English edition by Grenfell and Hunt, 1898), and in 1907 Lefebvre published seventeen fragments, comprising 1328 lines of four different plays—*The Hero*, *The Arbitration*, *The Woman with her Hair Shorn*, *The Woman of Samos*—discovered by him in 1906 at Kôm-Ishkaou in Middle Egypt (see the English version and notes by 'Unus Multorum,' 1909). From the surviving work of Menander the reason for his great reputation in ancient times is not at once apparent. A text of the principal fragments with translation by F. G. Allinson (1921) is in the Loeb series.

Ménard, LOUIS NICOLAS, chemist, poet and prose writer, philosopher, painter, historian, was born at Paris in 1822. In 1846 he discovered collodion. Always a socialist and in advance of the reform movements of his time, he found himself after the revolution of 1848 a political exile in London and in Brussels. Returning, however, in 1852 to Paris, and devoting himself to classical studies, he wrote as a Parnassian a volume of *Poèmes* (1885) containing some fine pieces, and produced among other works *Le Polythéisme hellénique* (1863), a book of high literary and philosophic value. Thereafter for some ten years he took to painting, and exhibited some not inconsiderable work. In literature *Les Réveries d'un païen mystique* (1876), an assortment of prose and verse, was his next work of note, and later he produced in history *Histoire des anciens peuples de l'Orient* (1882), *Histoire des Israélites* (1883), *Histoire des Grecs* (1884-86), &c. *Poèmes et Réveries d'un païen mystique* (1896) consisted of his collected poems and of extracts from his writings in philosophy and in literature. He died at Paris in 1901.

Mencius, the Latin form of MENG-TSE, the name of a Chinese sage, a contemporary of Plato and Aristotle, who was born in the province of Shan-tung in 372 B.C. He was brought up by his mother—the pattern of all mothers ever since in the eyes of the Chinese—and founded a school on the model of that of his great predecessor Confucius, for whom Mencius entertained a feeling of reverent admiration. When forty years of age he led out his disciples and travelled from one princely court to another during more than twenty years, seeking a ruler who would put into practice his system of social and political order. But, finding none, he again withdrew into retirement, and died in 289 B.C. After his death his disciples collected his conversations and exhortations, and published them as the *Book of Meng-tse*. The aim of Mencius's teaching was essentially practical—how men, especially the rulers of men, shall best regu-

late their conduct, both public and private. The philosophic root of his system is belief in the ethical goodness of man's nature, which quality he takes to be the essential characteristic of the humanity of men. From this root grow the cardinal virtues of benevolence, righteousness, moral wisdom, and propriety of conduct. It should be the aim of the individual to perfect himself by practising these virtues in all the relations of his social and political life. The flowering of this goodly plant which Mencius planted for the ordering of the lives of men, both individual and collective, assumed the form of a liberal and enlightened system of political economy. See books by Legge (1875; new ed. 1895) and Faber (trans. 1882).

Mendeans. See **MANDEANS**.

Mendel, GREGOR JOHANN (1822-84), renowned for his discoveries in connection with heredity. He was born at Heinzendorf bei Odrau in Austrian Silesia, the son of a small peasant proprietor. After leaving the 'Gymnasium' he entered the Augustinian cloister in Brunn, and was ordained a priest in 1847. At the expense of the cloister he studied science at the university of Vienna (1851-53), and on his return to Brunn took up teaching in the Realschule. In 1868 he was elected Abbot or Prälat of the Königskloster. It was before this, however, that he had utilised the large cloister garden for his now famous experiments on peas and hawkweeds. He also worked with bees, but there is unfortunately no record of his results. He took much interest in meteorology and sunspots, and was for a time President of the Naturforscherverein in Brunn. His fundamentally important work on heredity was entirely overlooked during his lifetime, and was not recognised at all till its rediscovery and confirmation in 1900 by De Vries, Correns, and Tschermak. During the last ten years of his life he became involved in a protracted quarrel with the government and in racial controversy. See biographical notice in Bateson's *Mendel's Principles of Heredity* (new ed. 1913); and the articles **HEREDITY**, **HYBRID**, **CELL**.

Mendeléeff, DMITRI IVANOVICH (1834-1907), chemist, was born at Tobolsk, studied at St Petersburg, and ultimately became professor of Chemistry in the university of St Petersburg in 1866. He enriched every section of chemical science, but is especially distinguished for his contributions to physical chemistry and chemical philosophy. He almost anticipated Andrews as to the critical temperature; but his great triumph was the discovery and formulation of the Periodic Law of the atomic weights (see **ATOMIC THEORY**). His *Principles of Chemistry* (1868-70) has gone through many editions, and been translated into most European languages, into English in 1891.

Mendelssohn, MOSES, was born 6th September 1729, at Dessau, the son of a poor Jewish schoolmaster called Mendel; and coming to Berlin at thirteen, he contrived, spite of severe privations, to study languages and philosophy. After years of comparative poverty he became the partner of a rich silk-manufacturer, whose children he had educated. The intimate friend of men like Lessing, Sulzer, Nicolai, he, directly and indirectly, contributed in a vast degree to the abolition of the disgraceful laws and brutal prejudices against the Jews. On the other hand, he acted in the most beneficial manner on his own co-religionists, by rousing them from the mental apathy with which they regarded in his day all that had not a distinct reference to religion, and by waging fierce war against their own religious and other prejudices. He died 4th January 1786, and Ramler wrote the following epitaph on him: 'True to the religion of

his forefathers, wise as Socrates, teaching immortality, and becoming immortal like Socrates.' He was the prototype of Lessing's *Nathan*, and was called a 'second Moses.' He was a diligent student of Locke, Shaftesbury, and Pope: a zealous defender of enlightened Monotheism, and, in spite of Lessing, strongly anti-Spinozist. His principal works are a volume on Pope as a philosopher, along with Lessing (1755), on the Sensations (1755), on Evidence in Metaphysics (1763); *Phaedon* (1767), a dialogue on the immortality of the soul in the manner of Plato; *Jerusalem* (1783), a defence of Judaism as a religion; *Morgenstunden*, essays in refutation of Pantheism and Spinozism. His works were edited in 1845 (8 vols.), and again in 1880 (2 vols.). See the *Life* by Kayserling (2d ed. 1887).

Mendelssohn-Bartholdy, FELIX, composer, was born at Hamburg on February 3, 1809. The family name was already remarkable by the fame of his grandfather, Moses Mendelssohn. Abraham, the second son of Moses Mendelssohn, had entered a banking business in Paris, but subsequently, on his marriage with Lea Salomon in 1804, settled in Hamburg. The French occupation in 1811 forced him to escape with his family to Berlin, where he founded the eminent firm of bankers known by his name. He resolved about this time to bring up his children as Protestant Christians, and added the name of Bartholdy to that of Mendelssohn in order to distinguish his own from the Jewish branch of the family.

The education he bestowed on Felix appears to have been as liberal as it was systematic. In his eighth year we find the child studying composition under Zelter and the pianoforte under Ludwig Berger, besides receiving lessons in drawing and the violin. Two years later he made his first public appearance, playing the pianoforte part in a trio at a concert in Berlin. With 1820 began that period of prolific production which lasted almost till his death. At the same time he entered upon a ceaseless round of gaiety and activity which largely determined his character. The home-life of the Mendelssohn family was eminently suited to the musical tendencies of the boy. A concert was given at the house on alternate Sunday mornings, when some of Felix's compositions generally found a place in the programme. Within the next few years he formed the acquaintance of such men as Goethe, Weber, and Moscheles, and had composed his Symphony in C minor and the B minor Quartet. A short visit to Paris with his father in March 1825 did not impress him favourably with the French musicians.

The following August saw the completion of his opera, *Camacho's Wedding*, which was destined to be the beginning of his unpleasant relations with the Berliners; and his well-known Octet for strings was finished in October. With the composition of the *Midsummer Night's Dream* overture, in August 1826, Mendelssohn may be said to have attained his musical majority, and his lessons with Zelter ceased. On April 29, 1827, the opera *Camacho's Wedding* was produced in Berlin. Though received with vehement applause it never reached a second performance, owing, among other reasons, to the illness of one of the principal singers, and the personal criticisms on the work in the press. Soon after this Mendelssohn commenced the formation of a small choir of sixteen voices, which met at his house for the purpose of studying Bach's Passion Music; and, in spite of the difficulties of the work and the determined opposition of Zelter, the scheme culminated in the famous performance by the Singakademie on March 11, 1829, the first since Bach's death. For some reason, however, his success did not improve his relations with Berlin musicians. Accordingly, being now twenty years old, he

resolved to leave home and to visit the different countries of Europe. England, afterwards the land of his most pleasant associations, was his first destination. He arrived in London on April 21, 1829, and was warmly welcomed by the Philharmonic Society. He made his first appearance at one of their concerts, when he conducted his Symphony in C minor. A tour through Scotland in the summer inspired him with the *Hebrides* overture and the Scotch Symphony.

During the next year he visited Munich and Vienna. By October he had reached Venice, and the following winter he spent in Rome. Returning to Munich he proceeded thence to Paris, paying his second visit to London in April 1832. He shortly afterwards returned to Berlin, having been absent three years. His success in conducting the Lower Rhine festival at Düsseldorf in 1833 led to his being offered the entire direction of the music for three years. But his stay at Düsseldorf was full of responsibilities and worries, and in October 1835 he left to conduct the Gewandhaus concerts at Leipzig. In 1837 he married Cecile Jeanrenaud, and at Birmingham in the same year conducted his *St Paul*, first heard at Düsseldorf in 1836. His attention was now chiefly devoted to Leipzig, but September 1840 found him again at Birmingham conducting the *Lobgesang*. About this time Mendelssohn was requisitioned by the king of Prussia to go to Berlin to assist in the foundation of an Academy of Arts; and, though loth to leave Leipzig, he removed to Berlin in May 1841, a stay not exceeding one year having been agreed on. The king's idea of reviving the ancient Greek tragedies led to the composition by Mendelssohn of the music to the *Antigone* and *Edipus*.

In 1843 he had the satisfaction of seeing his favourite scheme carried into effect by the opening of the new music-school at Leipzig, with Schumann and David among his associates. He was in London the following year to conduct the last five concerts of the Philharmonic season; and in 1846 he paid his ninth visit to England for the production of *Elijah*, which took place at Birmingham on 26th August. But his hard work was now beginning to tell on him, for, although his Berlin duties and his position as chief of the Leipzig Conservatorium entailed constant labour and anxiety, he persisted in carrying out all his engagements. He had scarcely returned from his tenth and last visit to England, in May 1847, when the news of his sister Fanny's death reached him. Periods of illness and depression rapidly followed; and on 4th November 1847 he died at Leipzig.

In stature Mendelssohn was short, and his handsome countenance was of a decidedly Jewish cast. He was eminent both as pianist and organist, especially in his rendering of the works of Bach, Mozart, and Beethoven. He moreover possessed a remarkable facility of improvisation. His gifts also included a talent for landscape-drawing; and he left behind him a whole series of sketches illustrating his different journeys. His music dwells almost exclusively on the sunny and gay side of life. Rarely, if ever, does he touch the innermost depths of passion and feeling. But he was, like Handel, one of the few composers who appealed to English audiences; his *Elijah* was long almost as popular as the *Messiah* itself.

See two collections of his Letters (1861 and 1863; trans. by Lady Wallace, 1862-63), those to the Moscheles (1888), and the selection ed. Alexander and Grove (1894); the *Lives* by Benedict (1850), Moscheles (1873), Lampadius (1886), Reissmann (1892), Rockstro (1884; new ed. 1923), Bellaigue (1907), Dahms (1919); *Reminiscences* by Devrient (1869; trans. by N. Macfarren), and Hiller (1874); *Grove's Dictionary*; and Hensel, *Die Familie Mendelssohn* (1879; trans. 1882).

Mendès, CATULLE, French poet and prose writer, was born at Bordeaux of Jewish parentage, 22d May 1841. He was one of the founders of the Parnassian school, and in 1863 (*Philomèle*) and after published various collections of poems all distinguished by their elegance. Displaying at the same time astonishing versatility and fecundity he wrote also numerous erotic novels (*Le Roi vierge*, 1880; *Méphistophéla*, 1890; *La Maison de la vielle*, 1894; *Gog*, 1897; &c.), collections of short stories, and plays (*La Part du roi*, 1872; *Justice*, 1877; *La Femme de Tabarin*, 1887; *Médée*, 1898; *La Reine Fiammette*, 1898; *Scarron*, 1905; *Glatigny*, 1906; &c.), produced several libretti (*Le Capitaine Fracasse*, 1878, music by Pessard; *Le Fils de l'étoile*, 1904, music by Erlanger; *Ariane*, 1906, music by Massenet; &c.), and in addition did valuable work in criticism, as *Richard Wagner* (1886) and *L'Art au théâtre* (3 vols. 1896-1900), a collection of journalistic work in dramatic criticism. On 9th February 1909 his dead body was found in the railway tunnel of Saint Germain. See work in French by A. Bertrand (2d ed. 1908).

Mendicancy. In spite of the stringency of the laws against vagrancy and begging, and the numerous aid societies in every town in Britain for the relief of the poor, quite an army of men, women, and children wander from place to place, and pick up a living by soliciting alms. This class is largely recruited from the lazy, idle, drunken, and vicious, though there is always a certain percentage who are really the victims of misfortune. Though the law is against begging—English statutes for the repression of mendicancy date from the 14th century—there is no law against giving to beggars. But indiscriminate charity only feeds the evil it seeks to remove. The truest charity consists in helping people to help themselves. There are innumerable societies for improving the condition of the poor. The relief given may consist in supplying immediate necessities, helping them to get into hospitals and convalescent homes, to emigrate, or to secure temporary work. Tickets are in some cases supplied to subscribers, which entitle a third person to whom they may be given to one meal. Tickets giving a right to a night's shelter can also be had, to be given instead of money. Nearly all European nations have tried to deal with mendicancy, but generally with little success. In Mohammedan countries alms-giving is a religious obligation, and mendicants abound. See POOR-LAWS, SALVATION ARMY, VAGRANTS.

Mendicant Orders, certain religious associations in the Roman Church, which, carrying out the principle of religious poverty and self-humiliation to its fullest extent, make it a part of their profession to denude themselves of all property, whether real or personal, and to subsist upon alms. In the mendicant orders alms were commonly collected by the lay-brothers—in some, by actual solicitation, in others, by the ringing of the convent bell when the stock of provisions was exhausted. See the articles DOMINICANS, FRANCISCANS, CARMELITES, AUGUSTINIANS; also FRIAR.

Mendip Hills, a range in Somersetshire extending 23 miles south-eastward from Weston-super-Mare to Shepton Mallet and 3 to 6 miles in breadth. The highest point is Black Down (1067 feet). The limestone of the Mendips is pierced by numerous caverns (see CHEDDAR), some of which have yielded prehistoric remains. Lead-mining, carried on from pre-Roman days, is now all but extinct. Calamine-mining, a later industry, is dead.

Mendoza, a western department of the Argentine Republic, with an area of 57,000 sq. m., and

a population of 333,000. The Andes occupy the western portion: Aconcagua (22,427 feet), the highest peak in America, is on the north-west frontier. The rest of the province is pampa land, fertile wherever it can be irrigated by the waters of the Mendoza and other streams, but elsewhere almost worthless. The annual rainfall is only 8 inches. Minerals, especially copper, abound, and are beginning to be worked; petroleum and coal have also been found. Vines flourish, and a large quantity of wine is exported to the other provinces. —The capital, Mendoza, 650 miles by rail W. by N. of Buenos Aires, is on a transcontinental railway, which reached this point in 1884. It is a handsome town, lying among vineyards and gardens, 2320 feet above the sea; its streets have shade-trees and streams of running water, and the alameda is the most beautiful on the continent. An active trade is carried on with Chile. An earthquake in 1861 destroyed Mendoza (founded 1559) and 13,000 of its 14,600 inhabitants; many of the ruins are still visible in the larger city which has been raised on its site. Pop. 60,000.

Mendoza, the name of an illustrious family that throughout Spanish history distinguished itself wherever distinction was to be won, in war, statesmanship, diplomacy, the church, and literature. A descent from the Cid has been claimed for it; but it was of Basque origin, and its progenitors the lords of Biscay some generations before the Cid's time. Of its more notable members the first is Iñigo Lopez de Mendoza, created Marquis of Santillana by John II. of Castile in 1445 for his services on the field of Olmedo and elsewhere. Besides being a gallant soldier, he was a wise statesman and a sturdy patriot, and in himself a proof of the truth of his own saying, that 'the lance never blunted the pen, nor the pen the lance,' for among the poets he stood next to Juan de Mena, and his exquisite little song of the 'Vaquera de la Finojosa' has secured a place for him in every Spanish anthology. He served literature, moreover, by leaving an excellent account of the Provençal, Catalan, and Valencian poets, and he has a further claim to remembrance as the first folklorists and the first collector of popular proverbs 'such as the old women repeat over the fire.' The most famous of his six sons was Pedro, Archbishop of Toledo, commonly called 'The Grand Cardinal,' who was for many years the trusted prime-minister of Ferdinand and Isabella, a man whose integrity and nobleness of character, no less than his commanding abilities, make him a prominent figure in an age by no means poor in great men.

The best known of the name is the marquis's great-grandson, DIEGO HURTADO DE MENDOZA (1503-75), the strong-handed lieutenant to whom Charles V. entrusted the conduct of his Italian policy and the representation of his views at the Council of Trent. He inherited a full measure of his great-grandfather's gifts as a statesman and as a man of letters. Almost as much as his kinsman Garcilaso de la Vega and Juan Boscan he was instrumental in grafting Italian poetry on the Spanish stem, but as a poet he was more national than either of his allies. His largest work is his *War of Granada*, a history of the revolt of the Moriscos in 1568-70 against the oppression of Philip II. It is constructed on Latin models, but a masterpiece of Spanish prose, marked throughout by rare narrative power, and by a generous spirit towards the miserable Moriscos which is rarer still. That work of genius, the first picaresque novel, *Lazarillo de Tormes*, was long ascribed to Hurtado de Mendoza, but the attribution is now commonly rejected, though there is something to be said for Mendoza's claim.

Menelaus, in ancient Greek heroic history, was king of Lacedæmon, the younger brother of Agamemnon, and husband of the famous Helen (q.v.).

Menes. See EGYPT (*Chronology and History*).

Menevian, one of the subdivisions of the Cambrian System (q.v.).

Menger, KARL, generally regarded as the founder of the Austrian school of economics, was born at Neu Sandez, in Galicia, 23d February 1840. Educated at Prague, Vienna, and Cracow, he became in 1873 professor of Economics at Vienna, where, except in 1876-78 when he was private tutor in political economy and statistics to Prince Rudolf of Austria, he continued till his retirement in 1903. In 1900 he was appointed a life member of the Austrian upper house. As an economist Menger owed much to Walras and Jevons. In contrast to the German historical school, which tended to lay stress on facts, he was attracted rather by theory and speculation, and very early became an adherent of the conception of marginal utility, which for him and his followers was fundamental. Throughout his analytical work was brilliant. His principal works are *Grundsätze der Volkswirtschaftslehre* (1871), *Der Übergang zur Goldwährung* (1882), *Die Irrtümer des Historismus* (1884), *Zur Theorie des Kapitals* (1888), *Grundsätze einer Klassifikation der Wirtschaftswissenschaften* (1889), and *Beiträge zur Währungsfrage in Oesterreich-Ungarn* (1892). His collection of works on economics was famous. He died at Vienna, 26th February 1921.

Mengs, ANTON RAPHAEL, painter and writer on art, was born at Aussig, in Bohemia, 12th March 1728. His father, Israel Mengs, was himself a painter, and from him young Raphael received his first instructions in art. At the age of thirteen he went to Rome, where he remained three years. On his return to Dresden in 1744 he was appointed court-painter to the king of Poland and Saxony, but was not prevented from living at Rome, where he became a Catholic and married. In 1754 he became director of the school of painting of the Capitol. On two occasions (1761-70 and 1773-76) he visited Spain, where he produced his most celebrated effort; it represents the Apotheosis of the Emperor Trajan, and is executed on the dome of the grand saloon in the royal palace at Madrid. He died at Rome, 29th June 1779. He was a learned and scholarly painter, but his works, though lofty in their subjects, seldom exhibit more than a correct and cultivated taste. His writings were edited in 1780 (Eng. trans. 1796).

Meng-tse. See MENCIVS.

Menhaden (*Brevoortia tyrannus*), the name, especially in Massachusetts and Rhode Island, of a species of herring or shad, abundant off the eastern coast of the United States. Other local names are Whitefish and Hardhead (in Maine), Bony Fish and Mossbunker (in New York). It is much used for bait and is very rich in oil, while the refuse furnishes valuable manure. Economically it is one of the most important North American fishes. See G. B. Goode's *Natural History of the Menhaden* (Washington, 1879).

Menhir (Breton *men hir*, long stone), a name in archaeology for Standing Stones (q.v.).

Menier, ÉMILE JUSTIN (1826-81), French manufacturer and writer, was born at Paris and died at Noisiel. He established at Noisiel a celebrated chocolate factory, with a branch in London, chemical works at St Denis, and a sugar manufactory at Roze, besides a rubber factory, and in Nicaragua a cocoa plantation. For his workers he instituted philanthropic schemes. A warm advocate of free trade, he expounded his views

in *Économie Rurale* (1875), *L'Avenir Économique* (2 vols. 1875-79), &c.

Menin, a town of Belgium, 7 miles SW. of Courtrai, on the left bank of the Lys, which separates it from France. There are textile and tobacco manufactures. Fortifications of 1685 by Vauban were razed in 1748 by the Treaty of Aix-la-Chapelle. During the Great War the town (captured by the Germans October 1914; recaptured by the British October 1918) and neighbourhood witnessed some of the fiercest fighting. Pop. 20,000.

Meningitis (Gr. *meninx*, 'a membrane') is the term employed in medicine to designate inflammation of the membranes investing the brain and spinal cord, of which in this relation the innermost—the *pia-mater*—is the most important. Far the most frequent form of meningitis in Britain is the tubercular, which for convenience is described under its old name of Hydrocephalus (q.v.); the main symptoms of other forms are similar.

Epidemic cerebro-spinal meningitis, or *Cerebro-spinal fever*.—Outbreaks have occurred from time to time in the 19th and 20th centuries in the northern hemisphere, less frequently in the British Islands than in most of the other countries where qualified observers are found, of an epidemic disease affecting chiefly the membranes of the brain and cord. It usually begins suddenly with fever and violent headache; vomiting, giddiness, stupor, delirium, and other nervous symptoms succeed, the most distinctive of which is a peculiar rigidity of the muscles of the neck and back. The disease is extremely variable in severity; sometimes it is fatal in less than twenty-four hours; sometimes so slight as only to confine the patient to bed for a few weeks. The majority of cases lie between these extremes, improvement in favourable cases beginning after a week or two. Convalescence is often very slow. The disease occurs chiefly in children and young adults. The causal organism is the *Diplococcus meningitidis*, which is believed to gain access to the interior of the head through the nose. A serum which destroys this organism has been much used in treatment of severe cases.

Simple meningitis (i.e. not traceable to tubercle or to the epidemic form) is most often caused by injury, but may result from disease of the skull, pyæmia, and other diseases, especially by infection from a suppurating middle ear. It usually begins, unlike the tubercular form, quite suddenly; and it is an extremely fatal disease; but the outlook is not quite so hopeless in simple meningitis as in the tubercular form. The essentials of treatment are rest and quiet in a darkened room, and little food of the lightest kind. It is often necessary to perform an operation for disease of the ear or other cause of the meningitis.

Meningocele. See ENCEPHALOCLE.

Menippus, a satirist who lived in the first half of the 3d century B.C., was born a Phœnician slave, and became a Cynic philosopher. His works in Greek have perished, and he is known only through the imitations of Marcus Terentius Varro (q.v.), whose own fragments bear the title of *Menippean Satires*.—The name was adopted as title for a famous French collection of political satires in prose and verse, the *Satire Ménippée*, published in 1594 against the Holy League and in favour of religious toleration.

Menispermaceæ, a family of dicotyledons. The type-genus *Menispermum* consists of *M. canadense*, from Atlantic America, popularly called 'moon-seed,' which really is the meaning of the generic name, and *M. dahuricum*, from eastern Asia. Menispermaceæ comprise sixty-three genera, many of which—e.g. *Fibraurea*, *Jatrochiza* (see CALUMBA),

Cissampelos (q.v.), Chondodendron (see PAREIRA-BRAVA), Tinospora, Coscinium, Stephania, Cocculus, Pachygone—furnish pharmaceutical products or dye-stuffs.

Mennonites, a Protestant sect combining some of the distinctive characteristics of the Baptists and the Quakers. Their principal tenet is the administration of baptism only upon confession of faith; consequently they do not baptise infants. They attach more importance to the ordering of the Christian life than to doctrinal points, ranking discipline and rectitude of life before learning and the scientific elaboration of dogmas. They refuse to take oaths, to bear arms, to fill civic and state offices, condemn every kind of revenge and divorce (except for adultery). The church is the community of the saints, which must be kept pure by strict discipline. Grace they hold to be designed for all, and their views of the Lord's Supper fall in with those of Zwingli; in its celebration the rite of feet-washing is retained in most congregations. They have bishops, preachers, and deacons. The first congregation to profess these principles was formed at Zürich in 1525 by three men, Grebel, Manz, and Blaurock. Thence the sect spread rapidly through Switzerland and the south of Germany and Austria, establishing itself in greatest strength at St Gall, Augsburg, and Strasburg. But a bitter persecution, in which 3000 perished, caused many to move into Moravia and into Holland. Contemporaneous with the Zürich congregation and its first years of propagandism was the appearance in Westphalia of the Anabaptists (q.v.), a sect professing some similar views, but guilty of most reprehensible fanatical excesses, in which the Swiss party had no share. After the suppression of the Anabaptists in Münster Menno Simons (1492-1559), who denounced the blasphemous zealots of Westphalia, organised the scattered members and congregations of the more sober-minded throughout Holland and north Germany. His influence became so paramount that his name has been used ever since to designate the sect as a religious body. Dissensions broke out amongst them at a later time both in Switzerland and Holland, chiefly as to the degree of strictness of discipline to be enforced. In 1620 the stricter Ammanite or Upland Mennonites separated from the more tolerant Lowland Mennonites in Switzerland. In Holland the first disruption occurred in 1554; the more liberal section in north Holland were called Waterlanders, though they exchanged the name of Mennonites for Baptist Communities. The advocates of greater strictness showed much want of cohesion. All the Dutch Mennonites were, however, reunited in 1801.

In 1783 Catharine of Russia introduced colonies of German Mennonites into south Russia; others joined them after 1867. But in 1871—at which time they numbered close upon 40,000—the Russian emperor decreed that they should be liable to conscription for the army and should be deprived of certain others of their privileges. This caused many of them to emigrate to the United States, where they settled principally in Minnesota and Kansas; others proceeded to Brazil. But Mennonite refugees from Alsace, the Palatinate, and Holland had already reached America as early as 1683, in which year the first Mennonite church in the United States was organised at Germantown in Pennsylvania. The sect was the first to protest against slavery. Nearly all Mennonites throughout the world are farmers; for culture, integrity, and philanthropic enlightenment they are everywhere highly regarded.

See Bloupet ten Cate, *Geschiedenis der Doopsgezinden* (5 vols. 1839-47); J. A. Starck, *Geschichte der Taufe und*

der Taufgesinnten (1789); N. Browne's *Life of Menno* (Phila. 1853); Smissen, *Kurzgefasste Geschichte der Mennoniten* (Summerfield, Illinois, 1895); Wedel, *Abriß der Geschichte der Mennoniten* (Newton, Kansas, 1900-1904); A. Brons, *Ursprung, Entwicklung, und Schicksale der Mennoniten* (Amsterdam, 1912); and Krehbiel's *Mennonites of North America* (St Louis, 1895).

Menopome (*Cryptobranchus* or *Menopoma alleghaniensis*), a large North American amphibian, in the order Urodela. It is nearly 18 inches in length, entirely aquatic, notable for its voracity and vitality, as is suggested by the popular names

Menopome or Hell-bender (*Cryptobranchus alleghaniensis*).

'hell-bender,' 'alligator,' 'water-dog.' It feeds on worms and fishes, and often takes the bait off the angler's line. It is newt-like in appearance, with one pair of gill-openings persistent. The Giant Salamander of Japan (*C. japonicus*) is an allied species.

Mensheviki. See BOLSHEVIKI.

Menshikov, ALEXANDER DANILOVICH, a Russian field-marshal and minister of state, was born at Moscow about 1660 or 1663. Lefort, the favourite of Peter the Great, saw him selling tarts in the street, took him into his own service, and introduced him to the notice of his imperial master. Rising rapidly in the tsar's favour, he distinguished himself at the siege of Azov, and afterwards accompanied Peter in his travels to Holland and England. On the death of Lefort (1699) he was made chief favourite. During the years (1702-13) of the war with Sweden he played important parts at the siege of Schlüsselburg, at the battles of Kalisch and Pultowa—on the field of Pultowa Peter made him field-marshal—at the capture of Riga, in the occupation of Courland and Pomerania, and at the taking of Stettin. At the capture of Marienburg the woman who afterwards became the wife of Peter (Catharine I.) fell into Menshikov's hands, and was through him introduced to the tsar. Towards the end of Peter's reign Menshikov lost favour owing to his extortions and suspected duplicities. But when Peter died he secured the succession of Catharine, and during her reign and that of her successor, her youthful grandson, Peter II., he governed Russia with almost absolute authority. His ambitious schemes—he was about to marry his daughter to the young tsar—and the dislike of the old nobility led to his overthrow by the Dolgoroukis, who banished him to Siberia (September 1727) and confiscated his immense estates and treasures. He died 2d November 1729.—His great-grandson, ALEXANDER SERGEEVICH, was born in 1789. He served in the campaigns of 1812-15 and rose to the rank of general. In the Turkish campaign of 1828 he took Anapa after a short siege, but before Varna received so severe a wound as to compel his retirement. After his recovery he was made head of the Russian navy, which he raised to a high state of efficiency. In March 1853 he was sent as ambassador to Con-

stantinople, where his overbearing behaviour produced a speedy rupture between the Porte and the tsar, and brought about the Crimean War. In this war he commanded at the battles of Alma and Inkermann, and displayed great energy in defending Sebastopol; but in 1855 he was recalled because of a severe attack of illness. Menshikov was till his death on 2d May 1869 one of the most prominent members of the old Russian party.

Menstruation is the term applied to the discharge of blood which issues every month from the generative organs of the human female during the period in which she is capable of procreation. The first appearance of this discharge, to which the terms *menses* and *catamenia* (each having reference to the monthly period) are indiscriminately applied, is a decided indication of the arrival of the period of commencing womanhood, and is usually accompanied by an enlargement of the mammary glands and other less conspicuous changes. Among Teutonic races menstruation usually commences between the thirteenth and the sixteenth years, and terminates between the fortieth and fiftieth years. The interval which most commonly elapses between the successive appearances of the discharge is about four weeks, although it is often shorter; and the duration of the flow is usually three or four days, but is liable to great variations. The first appearance of the discharge is usually preceded and accompanied by pain in the loins and general disturbance of the system, and in many women these symptoms invariably accompany the discharge. As a general rule there is no menstrual flow during pregnancy and lactation, and its cessation is one of the first signs that conception has taken place. Anomalies and disturbances (retention, suppression, undue copiousness, &c.) of the menstrual discharge are a frequent cause or symptom of illness.

Mensur. See DUELLING.

Mensuration, the name of that branch of the application of arithmetic to geometry which teaches, from the actual measurement of certain lines of a figure, how to find, by calculation, the length of other lines, the area of surfaces, and the volume of solids. The determination of lines is, however, generally treated of under Trigonometry (q.v.), and surfaces and solids are now understood to form the sole subjects of mensuration. To find the length of a line (except in cases where the length may be calculated from other known lines, as in trigonometry) we have to apply the unit of length (in the shape of a footrule, a yard measure, a chain), and discover by actual trial how many units the line contains. But in measuring a surface or a solid we do not require to apply an actual square board, or a cubic block, or even to divide it into such squares or blocks; we have only to measure certain of its boundary lines or *dimensions*; and from them we can calculate or infer the contents. For example, to find the area of a rectangle it is sufficient to measure two adjacent sides and find the product of these in terms of the unit of length chosen; 7 feet $\times$ 3 feet = 21 square feet.

The areas of other figures are found from this, by the aid of certain relations or properties of those figures demonstrated by pure geometry; for instance, the area of a parallelogram is the same as the area of a rectangle having the same base and altitude, and is therefore equal to the base multiplied by the height. As a triangle is half of a parallelogram, the rule for its area can be at once deduced. Irregular quadrilaterals and polygons are measured by dividing them into triangles, the area of each of which is separately calculated. For the area of the circle, see CIRCLE. The volume of a rectangular parallelepiped is found in cubic

inches by multiplying together the length, breadth, and depth in inches; and the oblique parallelepiped, prism, or cylinder, by multiplying the area of the base by the height.

Mentana, a village 12 miles NE. of Rome, where, 3d November 1867, the Garibaldians were defeated by the papal and French troops; pop. 3000.

Menteith, LAKE OF, a beautiful sheet of water in south-west Perthshire, 17 miles W. by N. of Stirling. Lying 55 feet above sea-level, it has an utmost length and breadth of $1\frac{1}{2}$ and 1 mile, and a maximum depth of 77 feet. It sends off Goodie Water 9 miles east-south-eastward to the Forth, and contains three islets—Inchmahome, Inchalla, and Dog Isle. Inchmahome has remains of an Augustinian priory (1238), the refuge in 1547-48 of the child-queen Mary Stuart before her removal to France; whilst on Inchalla is the ruined tower (1427) of the Earls of Menteith. That title was borne by a Celtic line in the 12th century, and afterwards by a Comyn, Stewarts, and Grahams (1427-1694). See Dr John Brown's *Horæ Subsecivæ* (1858), and Sir W. Fraser's *Red Book of Menteith* (2 vols. Edin. 1880).

Menthol is a camphor obtained from oil of peppermint by cooling. It has been used by the Japanese for 200 years, and is known by them as Hakka-no-Hari; indeed, native gentlemen formerly always went about with a medicine-box containing this drug. The chief source is the *Mentha arvensis purpurescens*, the oil of which yields more menthol than that of peppermint. In many nervous affections, such as neuralgia, toothache, headache, &c., menthol in the form of cones often gives instant relief. When the cone is rubbed on the skin one of two actions may result: the menthol rapidly evaporating a sensation of cold may be caused; but if evaporation be prevented it acts as a rubefacient, producing a feeling of warmth. Menthol has also antiseptic properties, and is used with success in solution in diphtheria, &c. It has an odour resembling but differing from that of oil of peppermint. It is liable to be adulterated with thymol, eucalyptol, &c., and then is often irritating to the skin.

Mentone (Fr. *Menton*), a town in the department of Alpes Maritimes, France, is pleasantly situated on the Mediterranean, $1\frac{1}{2}$ mile from the Italian frontier and 14 miles by rail NE. of Nice. Owing to its southern exposure, and the fact that spurs of the Alps shelter it on the north and west, it enjoys a beautiful climate—average for the year 61° F.—and so has become a favourite winter resort of invalids and health-seekers from England, Germany, and other countries. The town stands on a promontory that divides its bay into two portions; the native town clings to the mountain side, whilst the hotels and villas for the visitors extend along the water's edge. The harbour is protected on the south and west by a sea-wall (1889). There is trade chiefly in olive-oil, wine, lemons, and skins. Great damage was done to the place by an earthquake in February 1887. Pop. 20,000. In the 14th century it was purchased by the lords of Monaco, and, except during the period of the revolution and down to 1815 when France held it, the princes of Monaco kept possession till 1848. In that year Mentone (with Roquebrune) declared itself a free town under Sardinian protection, and in 1860 voted for annexation to France, the originally desired annexation to Sardinia not having been carried out. In the Grimaldi Caves near (in Italian territory) prehistoric human skeletons were found. See ANTHROPOLOGY.

Mentor, the son of Alcimus, and trusted friend of Ulysses, who, on setting out for Troy, left him the charge of his household. By him the young

Telemachus was educated, and Mentor's name has become a synonym for an instructor and guide, a usage due more to Fénelon's *Télémaque* than to the *Odyssey*.

Menura. See LYRE-BIRD.

Menza'leh, LAKE, a coast lagoon of Egypt extending east from the Damietta branch of the Nile, is separated from the Mediterranean by a narrow strip of land, with several openings. Its surface, 460 sq. m. in extent, is studded with islands, the most interesting of which is Tennees, the ancient Tennesus, with Roman remains of baths, tombs, &c. Its waters are full of fish, and its shores abound in wild-fowl. The Suez Canal passes through the eastern portion. The lake has an average depth of not more than 3 feet, except when the Nile, mouths of whose delta reach it, is in flood; and it is being gradually drained.

Menzel, ADOLF (1815–1905), painter, lithographer, illustrator, and engraver, was born at Breslau, and is best known for his drawings and oil-paintings illustrative of the times of Frederick the Great and the Emperor William I.—pictures characterised by historical fidelity, strong realistic conception, originality, and humour. His 'Adam and Eve,' 'Christ among the Doctors,' and 'Christ expelling the Money-changers' are also notable pictures. See *Life* by Wessely (1873) and the critical works of Jordan (1890–1905).

Menzel, WOLFGANG, an eminent German author, was the son of a medical practitioner, and was born at Waldenburg, in Silesia, 21st June 1798. He studied at Jena and Bonn, was for four years schoolmaster at Aarau in Switzerland, and in 1825 returned to Germany. He first made himself known in the literary world by his witty *Streckerse* (1823). He subsequently lived mainly in Stuttgart, where he died 23d April 1873. He edited and contributed to literary magazines, and wrote a very large number of works—poems, romances, histories, literary criticism, political polemics, and Christian theology. The most important were a history of Germany (1825; Eng. trans. 1848), of German literature (1827; Eng. trans. 1840), of German poetry (1858), of Europe (1853–57), and of the world (*Allgemeine Weltgeschichte*, 16 vols. 1862–72), on Prussia's place in Germany (1866 and 1870), mythological researches (1842), the pre-Christian doctrine of immortality (1869), and autobiographical *Denkwürdigkeiten* (1876). He was almost constantly involved in controversy, attacking with equal zeal theological rationalists and political radicals, all whose tendencies seemed 'dangerous' to the Christian religion or the German monarchies, such as 'the Young Germany party' after 1830. Börne (q.v.) retaliated in the *Franzosenfresser* ('Frenchman-eater').

Mephistopheles, the name of one of the best-known personifications of the principle of evil. The word has been very variously explained, but is probably of Hebrew origin, like most names of devils in the history of magic, confounded with, and approximated in form to, the Greek *μηφιστοφίλης*, 'one who loves not light.' Mephistopheles owes all his modern vitality to Goethe's *Faust* (q.v.).

Meppel, a town in the Netherlands province of Drenthe, 18 miles N. by E. of Zwolle, has a trade in butter, and linen manufactures. Pop. 11,000.

Me'quinez. See MIKNAS.

Meran, a town in the Trentino situated at the south side of the Alps 100 miles by rail S. by W. of Innsbruck, is a celebrated winter-resort, especially for sufferers from chest diseases, has a 15th-century castle, a 14th-century Gothic church, &c.

Pop. 11,000. The district is German-speaking, but was assigned to Italy in 1919.

Merbecke. See MARBECK.

Mercadante, SAVERIO, musical composer, was born at Altamura in Southern Italy, 26th June 1797, studied music at Naples, and began his career as a violinist and flutist. In 1818 he produced the first of some sixty operas, of which the more noteworthy are *L'Apoteosi d'Ercole* (1819), *Anacreonte* (1820), *Elisa e Claudio* (1821), *Donna Caritea* (1826), *I Briganti* (1836), *Il Giuramento* (1837), and *La Vestale* (1842). From 1827 to 1831 he was in Spain; in 1833 he was appointed musical director in the cathedral at Novara, and in 1840 of the conservatory of music at Naples. He died in that city, 17th December 1870—blind since 1861.

Mercantile Law, the branch of municipal law which is similar, and in many respects identical, in all the trading countries of the world. An understanding was earliest established in the department of maritime law, the history of which begins with such codes as the *Consolato del Mare* (see CONSULATE OF THE SEA), published at Barcelona in 1494, and includes such a series of regulations as the various British Merchant Shipping Acts, which consolidate and amend the law as to seamen and their contracts with employers, desertion, provisions, unseaworthy ships, pilotage, signals, deck cargoes, the load-line, life-saving apparatus, &c. Mercantile and maritime law is dealt with in this work under a large number of heads, as

Apprentice.	Debt.	Partnership.
Bankruptcy.	Insurance.	Plimsoil.
Bill.	International Law.	Weights and Measures.
Company.	Master and Servant.	

Mercantile System, that system in political economy which regards it as a government's chief end to secure a favourable balance of trade—to get the country to import as little as possible of the produce of other countries, and export as much as possible of its own, so that more money is received than is paid away. The policy of the Emperor Charles V. was regulated by this aim, as was that of Henry VIII. and Queen Elizabeth in England; and the Navigation Laws (q.v.) of Cromwell founded the English empire of the seas. Colbert (q.v.) was regarded as the most systematic mercantilist. Among English exponents of the system were Sir Josiah Child and Sir William Temple. See BALANCE OF TRADE, POLITICAL ECONOMY.

Mercator (the Latinised form of KREMER), a Flemish mathematician and geographer of German extraction, who lived 1512–94. See MAP.

Mercedes, (1) a city in Argentina, 61 miles by rail W. of Buenos Aires, is an important agricultural and pastoral centre, and has many fine buildings; pop. 22,000 (many Irish).—(2) A town of Argentina, 55 miles by rail ESE. of San Luis; pop. 18,000.—(3) The capital of Soriano province, in Uruguay, an agricultural and live-stock centre; pop. 23,000.

Mercenaries, or STIPENDIARIES, men who received pay for their services as soldiers, especially as distinguished from the feudal and general levies owing military service to the crown. Such men were often foreigners, and the name has come to mean only foreign auxiliaries. Hired professional soldiers appear very early in the history of military organisation (see ARMY). Foreign mercenaries appear in the armies of Alexander the Great and the Romans. They were common in all armies, but generally engaged for a single campaign only. In England, Harold had a body of Danes in his army when he defeated the Norwegian king—

the *huscarls*, a body originally established by Canute. William III. had for some time a body of Dutch troops in his pay after he became king of England; and throughout the 18th century Hessian and Hanoverian regiments were constantly in the pay of the British government. Frederick II. of Hesse hired out 30,000 of his men—of whom only 17,313 returned at the close—to fight for Great Britain in the first American war; with the £2,000,000 received he did much to promote science, literature, and art, and to adorn his capital. During the Irish rebellion, again, in 1798, many Hessian troops were employed.

On the outbreak of the Continental war in 1793 it was determined to increase the British army by the addition of a large body of foreigners; and accordingly in 1794 an act was passed for the embodiment of the 'King's German Legion,' consisting of 15,000 men. These troops, who were increased in the course of the war to nearly double that number, distinguished themselves in various engagements, and formed some of the most reliable regiments. It was common during the Peninsular War to enlist deserters and prisoners of war into the British army, but such recruits were not to be trusted when opposed to their fellow-countrymen. Corps of French *émigrés*, as the Chasseurs Britanniques, which served through the Peninsular War and in America, the York Chasseurs, in which some Turks were enrolled when at Malta, and others, were also organised. The whole of the foreign legions were disbanded in 1815, the officers being placed on half-pay.

During the Russian war in 1854 the British government again had recourse to the enlistment of foreigners. The numbers authorised were 10,000 Germans, 5000 Swiss, and 5000 Italians, with the same pay as British troops. About half were enrolled, and had become very efficient, when hostilities ceased, and they were disbanded at a great cost for gratuities, &c. Foreigners may, on the signification through a secretary of state of royal consent, enlist into the British army, but the Army Act provides that the proportion of aliens in any corps at one time shall not exceed one to every fifty British subjects, and that no alien shall be eligible to hold a commission as an officer; this notwithstanding, however, any inhabitant of any British protectorate and any negro or person of colour may freely enlist, and when serving be deemed to be entitled to all the privileges of a natural-born British subject. British-born soldiers have often served abroad. There was a famous Scots Guard (q.v.) in France from the days of Charles VI. down to 1759; many Scotsmen fought for Gustavus Adolphus; and Englishmen, Scotsmen, and Irishmen, singly and in bodies, have served during troublous times in most European countries; see GORDON (PATRICK), KEITH, HOBART PASHA. A British legion was raised in 1836 by Sir De Lacy Evans to support the queen of Spain against the Carlists (see EVANS).

The Swiss auxiliaries used to form a regular contingent in many of the armies of Europe, especially of France and Italy. Over 1,000,000 served in France from the time of Louis XI. to that of Louis XIV. (1465–1715). After the French Revolution (see SWISS GUARDS) the cantons ceased publicly to hire out their subjects; in 1859 the Confederacy forbade recruitment for service abroad. The Papal Swiss troops have shrunk to a bodyguard. See CONDOTTIERI, FOREIGN LEGION, FREE-LANCES, IRISH BRIGADE.

Mercer, JOHN (1791–1866), calico-printer and chemist, invented a method (patented in 1850) of treating ('mercerising') cotton fibre by chemical process which imparts to the fabric a silky lustre. See CELLULOSE.

Merchandise Marks. See TRADE-MARKS.

Merchant Adventurers. See COMPANY.

Merchants, STATUTE OF, an English statute of 1285 amplifying the statute of Acton Burnell (q.v.). The statute allowed a creditor to seize the goods and hold the lands of a defaulting debtor until satisfaction of the debt.

Merchant Taylors' School, a great London day-school, with 500 boys, founded and governed by the master, wardens, and company of Merchant Taylors (see LIVERY). The first school-house in Suffolk Lane (1561) was destroyed in the great fire of 1666, but it was in 1671–74 rebuilt on the same site. When the Charterhouse School was removed into the country, the Merchant Taylors bought land from the governors of the Charterhouse for £90,000, and in 1873–74 erected, at a cost of £30,000, their present school-house on the site of the old gown boys' quarters. Richard Mulcaster was the first master, and among its scholars have been Edmund Spenser, Bishop Andrewes, James Shirley, Archbishop Juxon, Titus Oates, Lord Clive, Charles Mathews, Sir Henry Ellis, and Sir Frederick Treves. See the Rev. C. J. Robinson's *Register of the Scholars admitted to Merchant Taylors', 1562–1874* (2 vols. 1882–83).

Mercia, the great Anglian kingdom of central England. The name, originally limited to the district around Tamworth and Lichfield and the Upper Trent valley, refers to a 'march' or frontier that had to be defended against hostile Welshmen. The first settlements were most probably made in the second half of the 6th century, but Mercia first rose into real importance, and indeed grew into Middle England, under the vigorous rule of Penda (626–655). His nephew, Wulfhere (659–675), pushed back the Northumbrians, and extended the boundary southward to the Thames, and Ethelbald (716–755) spread his conquests round all the neighbouring states. But the mightiest kings of Mercia were Offa (757–795) and Cenwulf (796–819), and after their time its power rapidly declined before the invasions of the Danes on the one side, and the spread of the West Saxon kingdom on the other. At length it became one of the great earldoms, and Elfgar, Leofric, Edwin, and Morcar retained at least the shadow of past power. See ENGLAND (*History*).

Mercury. See HERMES, PLANETS.

Mercury, or QUICKSILVER (sym. Hg; atomic weight = 200; sp. gr. 13·6), one of the so-called noble metals, remarkable as being the only metal that is fluid at ordinary temperatures. It is of a silvery white colour, with a striking metallic lustre. When pure it runs in small spherical drops over smooth surfaces; but when not perfectly pure the drops assume an elongated or tailed form, and often leave a gray stain on the surface of glass or porcelain. Moreover, the pure metal, when shaken with air, presents no change upon its surface; while if impure it becomes covered with a gray film. It is slightly volatile at ordinary temperatures, and at 662° F. it boils, and forms a colourless vapour of sp. gr. 6·976. Hence it is capable of being distilled; and the fact of its being somewhat volatile at ordinary temperatures helps to explain its pernicious effects upon those whose trades require them to come much in contact with it—as, for example, the makers of barometers, &c. At a temperature of –39° F. it freezes, when it contracts considerably, and becomes malleable. In consequence of the uniform rate at which it expands when heated, from considerably below 0° F. to above 300° F., it is employed in the construction of the mercurial thermometer.

All mercurial compounds are either volatilised or

decomposed by heat; and when heated with carbonate of sodium they yield metallic mercury. Native or virgin quicksilver only occurs in small quantity, usually in cavities of mercurial ores. Of these ores by far the most important is a sulphide known as Cinnabar (q.v.). There are two means of obtaining the metal from cinnabar: the ore may be burned in a furnace, in which case the sulphur is given off as sulphurous acid, and the mercury is collected in a condensing chamber; or the ore may be distilled with some substance capable of combining with the sulphur—as, for example, with slaked lime or iron filings. The mercury as imported is usually almost chemically pure. If the presence of other metals is suspected, it may be pressed through leather, redistilled, and then digested for a few days in dilute cold nitric acid, which exerts little action on the mercury if more oxidisable metals are present; or better, in a solution of mercuric nitrate, which deposits mercury and takes up the more oxidisable metals. The mercury, after being washed with water, is chemically pure.

Mercury is first spoken of by Theophrastus (3d century B.C.); the name *hydrargyros* (whence comes the symbol Hg) dates from Dioscorides. Greeks and Phœnicians procured cinnabar from Almadén in Spain. After the discovery of the New World the mercury of Peru was famous. California now produces the great bulk of the mercury of commerce, and most of it comes from the New Almadén mine.

There are two oxides of mercury, the black suboxide, Hg_2O , and the red oxide, HgO . Both of these lose all their oxygen when heated, and form salts with acids. The black suboxide, although a powerful base, is very unstable when isolated, being readily converted by gentle warmth, or even by mere exposure to light, into red oxide and the metal: $\text{Hg}_2\text{O} = \text{HgO} + \text{Hg}$. The most important of its salts is the nitrate, $\text{Hg}_2(\text{NO}_3)_2 + 2\text{Aq}$, from whose watery solution ammonia throws down a black precipitate known in pharmacy as *Mercurius solubilis Hahnemannii*, from its discoverer, and consisting essentially of the black suboxide with some ammonia and nitric acid, which are apparently in combination. Of the red oxide the most important salts are the nitrate, $\text{Hg}(\text{NO}_3)_2 + 8\text{Aq}$; the sulphate, HgSO_4 , which is employed in the manufacture of corrosive sublimate; and the basic sulphate, $\text{HgSO}_4 \cdot 2\text{HgO}$, which is of a yellow colour, and is known as *Turpeth Mineral*.

The haloid salts of mercury correspond in their composition to the oxides. Of the most important of these—the chlorides—there are the subchloride, Hg_2Cl_2 , well known as Calomel (q.v.), and the perchloride, HgCl_2 , or corrosive sublimate.

The perchloride, HgCl_2 , when crystallised from a watery solution occurs in long white glistening prisms; but when obtained by sublimation it occurs in white transparent heavy masses, which have a crystalline fracture, and chink with a peculiar metallic sound against the sides of the bottle in which they are contained. This salt melts at 509°F ., and volatilises unchanged at about 570° . It has an acrid metallic taste. It is soluble in sixteen parts of cold, and in less than three parts of boiling water, and dissolves very freely in alcohol and in ether. Corrosive sublimate enters into combination with the alkaline chlorides, forming numerous distinct compounds. (A double chloride of ammonium and mercury, represented by the formula $\text{CH}_3\text{NCl} \cdot \text{HgCl}_2 + \text{Aq}$, has been long known as *sal alembrothi*.) It combines with oxide of mercury in various proportions, forming a class of compounds of great interest in theoretical chemistry, termed *oxychlorides of mercury*. On adding a solution of corrosive sublimate to a solu-

tion of ammonia in excess, a compound, which from its physical characters is termed *white precipitate*, is thrown down, the composition of which is $\text{HgN}_2\text{H}_6\text{Cl}_2$. Perchloride of mercury coagulates albumen and combines with the albuminous tissues generally, forming sparingly soluble compounds. Hence, in cases of poisoning with the salt, the white of raw eggs is the best antidote; and for the same reason corrosive sublimate is a powerful antiseptic, and is employed to preserve anatomical preparations.

Amongst the most important tests for this substance, which is not unfrequently used as a poison, may be mentioned (1) iodide of potassium, which, when added to a crystal or to a watery solution of chloride of mercury, gives rise to the formation of a bright scarlet iodide of mercury. (2) The galvanic test, which may be applied in various ways, of which the simplest is the 'guinea and key test,' devised by Wollaston. He placed a drop of the fluid suspected to contain corrosive sublimate on a guinea, and simultaneously touched it and the surface of the guinea with an iron key; metallic mercury was deposited on the gold in a bright silvery stain. (3) Precipitation on copper, and reduction. To apply this test we acidulate the suspected fluid with a few drops of hydrochloric acid, and introduce a little fine copper gauze, which soon becomes coated with mercury. On heating the gauze in a reduction tube the mercury is obtained in well-defined globules.

With iodine and bromine mercury forms two iodides and bromides, corresponding in composition to the chlorides. Both the iodides are used in medicine; the bromides are of no practical importance. The subiodide, Hg_2I_2 , is a green powder formed by triturating 5 parts of iodine with 8 of mercury, and is of far less interest than the periodide, HgI_2 , which is most simply obtained by precipitating a solution of corrosive sublimate by a solution of iodide of potassium. The precipitate is at first salmon-coloured, but soon changes into a brilliant scarlet crystalline deposit.

Sulphur forms two compounds with mercury—viz. a subsulphide, Hg_2S , a black powder of little importance, and a sulphide, HgS , which occurs naturally as Cinnabar (q.v.). *Sulphide of mercury* is thrown down as a black precipitate by passing sulphuretted hydrogen through a solution of a persalt of mercury (corrosive sublimate, for example). When dried and sublimed in vessels from which the air is excluded, it assumes its ordinary red colour. The well-known pigment *vermilion* is sulphide of mercury, and is sometimes obtained from pure cinnabar, but is more frequently an artificial product.

Mercury unites with most metals to form Amalgams (q.v.), several of which are employed in the arts. Of the numerous organic compounds of mercury it is unnecessary to mention more than the Fulminate (q.v.) and the cyanide, HgCN , which may be prepared by dissolving the red oxide of mercury in hydrocyanic acid, and is the best source from which to obtain cyanogen.

The uses of mercury are so numerous that a very brief allusion to the most important of these must suffice. It is employed extensively in the extraction of gold and silver from their ores by the process of amalgamation. Its amalgams have been largely employed in the processes of silvering and gilding, and some (as those of copper and cadmium) are employed by the dentist for stopping teeth. It is indispensable in the construction of philosophical instruments, and in the laboratory in the form of the mercurial bath, &c. It is the source of the valuable pigment vermilion. The use of its chloride in anatomical preparations has been already noticed; it is similarly found that wood,

cordage, and canvas, if soaked in a solution of this salt (1 part to 60 or 80 of water), are better able to resist decay when exposed to the combined destructive influence of air and moisture.

MEDICINAL USES OF MERCURY AND MERCURIALS.—Metallic mercury is used in medicine in a state of very fine division in the form of gray powder, blue pill, mercurial ointment, and other preparations. It is also used as mercurous and mercuric oxides and salts. As with other metals, the mercurial preparations have a local action and an action after absorption into the blood. The intensity of the local action varies, however, with the individual preparation; the persalts being soluble in water, and hence capable of precipitating albumen at once, are very irritating, while the mercurous salts and uncombined mercury, being insoluble in water, exert an effect only in so far as they are dissolved in the secretions. These differences in local action have a very great influence in determining their applications in medicine.

Locally, the various ointments, liniments, and plasters are used as stimulants, astringents, antiseptics, and parasitocides, the persalts are used as antiseptic lotions, while the protosalts are little employed locally, except Calomel (q.v.) in powder.

Absorption of mercurial preparations from the intestinal canal or skin takes place very readily, and in an hour or less the mercury may be detected in most of the secretions. After absorption into the blood all the preparations have the same action. In minute doses they act as alteratives, improving nutrition. In larger doses, such as are ordinarily used, they also exert profound alterative effects; but care must be exercised in their administration, otherwise symptoms of chronic poisoning are apt to ensue. These consist in excessive salivation, inflammation of the mouth and gums, and dyspepsia, while in severer cases caries of bone, nervous symptoms, a watery condition of the blood, albuminuria, cachexia, and other serious complications may occur. The mercurial preparations are given internally in syphilis, in serous inflammations, and in dropsy as diuretics. Certain of them, such as gray powder, blue pill, and calomel, are used as purgatives and as intestinal antiseptics.

The doses of the different preparations vary greatly, those of the persalts being very much smaller than in the case of the other preparations. Some persons are peculiarly susceptible to the action of mercurials, and show symptoms of chronic poisoning after very small amounts.

With regard to acute mercurial poisoning, this is due to irritation of the intestinal canal, and is only seen with the soluble salts when taken in overdoses. The perchloride (corrosive sublimate) has been most frequently employed for the purpose of poisoning. The symptoms come on immediately, with a burning pain in the throat and violent pain in the abdomen, with severe vomiting and purging. There is always a good deal of collapse. Albumen, in the form of white of egg, is the best antidote.

Mercury, Dog's (Mercurialis), a genus of plants of the natural order Euphorbiaceæ. The Common Dog's Mercury (*M. perennis*) is very common in woods and shady places in Britain. It has a perfectly simple stem, about a foot high, with rough ovate leaves, and axillary loose spikes of greenish flowers. It turns a glaucous black colour in drying, and the root contains two colouring substances, one blue and the other carmine. It is very poisonous. The mercury which some old writers mention as a potherb is not this plant, but English Mercury, or Wild Spinach (*Chenopodium Bonus-Henricus*). Annual Dog's Mercury (*M. annua*) is a much rarer British plant, and less poisonous. The leaves are indeed eaten in

Germany as spinach. Pliny mentions an ancient belief (not extinct), that if a woman after conception drink the juice of the male plant (the female in the botanical sense) she will give birth to a boy, and if of the female, a girl.

Mercy, SISTERS OF. See SISTERHOODS.

Mer de Glace. See ALPS, GLACIER.

Meredith, GEORGE, novelist and poet, was born in Hampshire, 12th February 1828, and made his first appearance as a poet with 'Chillianwallah' in *Chambers's Journal* for July 1849. This was followed in 1851 by a little volume of *Poems*, and in 1855 by *The Shaving of Shagpat; an Arabian Entertainment*, a highly original tale, in burlesque imitation of the manner of the Eastern story-teller. It shows a rich and brilliant imagination, and abounds in passages of tender feeling as well as of boisterous humour, but the incidents are involved and the machinery complicated, and reading is also made difficult by tantalising suggestions of hidden meanings which constantly elude one's grasp. In 1857 appeared *Farina: a Legend of Cologne*, a short story, reflecting the influence of German romance, which it partly imitates and partly parodies. The series of Meredith's greater and more characteristic works began in 1859 with *The Ordeal of Richard Feverel: A History of a Father and a Son*, a tragic romance, dealing with the larger problems of education, especially in its ethical aspects. The novel of *Evan Harrington*, an amusing comedy of social ambitions, followed in 1861. *Modern Love*, and *Poems of the English Roadside, with Poems and Ballads*, was published in 1862, 'Modern Love' being the title of a sequence of fifty sonnet-like poems which tell their story in a somewhat fragmentary manner, but with great truth of observation and strength of pathos. *Emilia in England* (1864), since 1886 known as *Sandra Belloni*, has for its subject one of Meredith's most fascinating and original characters; it is continued in *Vittoria* (1866), the scene of which is laid in Italy at the time of the political risings of 1848. In 1865 had appeared *Rhoda Fleming*, like *Richard Feverel* a tragedy; the romantic *Adventures of Harry Richmond* followed in 1871. *Beauchamp's Career* (1875) is perhaps the most perfectly constructed of all the series. *The Egoist* (1879) is a searching and remorseless study of a single aspect of refined selfishness. *The Tragic Comedians* (1881) is a somewhat close rendering of the well-known painful story of Lassalle's tragic end, founded upon the reminiscences of the Countess Racowitza. Other novels are *Diana of the Crossways* (1885), *One of our Conquerors* (1891), *Lord Ormont and his Aminta* (1894), and *The Amazing Marriage* (1895). Meredith, who was literary reader for Chapman and Hall for over thirty years, issued a revised edition of his novels in 1896-99 (32 vols.). *Poems and Lyrics of the Joy of Earth* (1883), *Ballads and Poems of Tragic Life* (1887), *A Reading of Earth* (1888), *A Reading of Life and other Poems* (1901), contain his chief poems. After his death, 18th May 1909, his *Last Poems* and his unfinished novel *Celt and Saxon* were published, and his unfinished play *The Sentimentalists* produced.

Critics have ranked Meredith as the foremost novelist of his day, and as one of the most invigorating and stimulative thinkers of his generation; at the same time he never obtained a wide public, his work appealing more to an expert than to a popular taste. Among the elements of his power are his wide, accurate, and sympathetic observation both of nature and of life, his inventive resource, his analytic and synthetic power, and his mastery of words. His descriptions of scenery are varied, vivid, and full of poetry, his delineations of phases of feeling, and especially of tender feeling, those of a

master. Few writers have created so many characters of ideal beauty, who are at the same time so thoroughly human and marked by the strongest individuality—real, breathing, talking personalities, whom the reader feels it a joy to have known. Among the ‘defects of his qualities’ may be mentioned a certain intricacy of plot, or rather perhaps want of clearness in working it out, arising from an exaggerated reticence; also a frequent over-elaboration of style and strainedness of wit that fatigues rather than exhilarates. And, though he is never ‘sensational,’ there is often a certain disregard of probability in the situations he invents. It was a purpose of Meredith’s, deliberately expressed and consistently carried out, to bring philosophy into the domain of fiction, and much of his writing deals more or less directly, in a serious manner, with the most important problems of politics, sociology, and ethics.

There is a memorial edition of Meredith’s works (27 vols. 1909–11); vol. xxvii. is a bibliography. His letters were edited by his son (2 vols. 1912). There is a critical estimate in Brownell’s *Victorian Prose Masters* (1902); and see works by Le Gallienne (1890), Jerrold (1903), Trevelyan (1906, 1912), Henderson and Selincourt (1907), Hammerton (1909), Photiadès (1910; trans. 1913), Crees (1918, 1921), Ellis (1919), Lady Butcher (1919).

Merezhkovsky, or **MEREJKOVSKY**, **DMITRI SERGEVICH**, Russian novelist, critic, and poet, was born in 1865 at St Petersburg, the son of an official of the imperial court. He was educated at St Petersburg, where he graduated, and throughout his work the influence of the classics, especially of the Epicurean writers, and of Nietzsche is clearly to be seen. His first work was done in poetry, his earliest collections of verse (1888 and 1892) gaining him a measure of renown. About the same time as this early verse he also produced excellent translations of several Greek and Latin authors, most notably of Æschylus, of Sophocles, and of Euripides. But it was as a novelist, and in a lesser degree as a critic, that Merezhkovsky was to achieve distinction. Of his novels his trilogy (*Christ and Antichrist*), of historical and philosophical romances (*The Death of the Gods*, 1896; *The Forerunner*, 1901; *Peter and Alexis*, 1905), is to be accounted his masterpiece. Here the theme, a favourite one of Merezhkovsky’s, is the undying struggle between Greek polytheism with its emphasis on happiness and beauty and Christianity with its recognition of suffering and death. In criticism, in *Eternal Companions* (1897), Merezhkovsky has written on old and modern European and Russian authors (Cervantes, Calderon, Flaubert, Ibsen, Pushkin, Maykov, Korolenko, &c.), but most important in this kind are *The Cause of the Decadence of Modern Russian Literature* and *Tolstoi and Dostoevski* (2 vols. 1901–2), the last considered the best work in its field. Apart from his intrinsic merits as a writer, Merezhkovsky is notable as marking a departure from the traditional humanitarianism and realism of Russian literature, and with Sologub (Teternikov) he is to be considered the founder of Russian modernism. Much of his work has been done into English. See HIPPIUS.

Merganser (*Mergus*), a genus of birds of the family Anatidæ, having a long, rather slender, straight bill hooked at the tip and notched at the edges. The genus embraces six species, nearly all inhabitants of the seas and coasts, and distributed over the northern regions of the Old and New World, and in Brazil and the Auckland Islands. The Goosander (q.v.) is the largest and best-known British species. The Red-breasted Merganser (*M. serrator*) is resident in Scotland, where it breeds not only on the coasts of Ross, Sutherland, and

the Hebrides, where it is abundant, but also on inland lochs and rivers. Its migrations extend southward to the lakes of Algeria and to Egypt. It feeds chiefly on small fishes. Its flesh is unpalatable. The Hooded Merganser (*M. cucullatus*), a smaller species, is a very rare visitor of Britain. It is found in North America, from the St Lawrence to Alaska, where it migrates as far south as Mexico, Cuba, Bermuda, and the Carolinas. The Nun or Smew (*M. albellus*) is a smaller species, passing the summer in the northern parts of the Old and New World, and ranging in winter as far south as India. Another species (*M. australis*) has as yet been found only in the Auckland Islands.

Mergui, a seaport of Burma, on the Tenasserim coast, just outside the principal mouth of the Tenasserim River. It exports rice, timber, dried fish, and mother-of-pearl shell, and imports cotton goods, husked rice from Rangoon, silk, and tea. Pop. 17,000.—The district of Mergui, 200 miles long by 40 wide, is the southernmost in Burma. Area, 9789 sq. m.; pop. (1881) 56,559; (1921) 135,465.

Mergui Archipelago, a group of islands in the Bay of Bengal, lying off the southern provinces of Burma; they are mountainous, some rising to 3000 feet, of picturesque beauty, and sparsely inhabited by a race called the Selungs, who barter edible birds’-nests with the Burmese and Malays for rice and spirits. Rubber abounds. Snakes and tigers, rhinoceros, deer, &c., are plentiful.

Mérida (anc. *Augusta Emerita*), a decayed town of Spain, on the right bank of the Guadiana, 30 miles E. of Badajoz. It is remarkable for its Roman remains, which include the Arch of Santiago, 44 feet high, and a bridge originally of 81 arches (17 were destroyed in 1812 during the Peninsular War), 2575 feet long and 26 feet broad, both erected by Trajan; others are the ruins of half-a-dozen temples, of an aqueduct, a circus, a theatre, a naumachia, a castle. There is also an old Moorish palace. Mérida was built in 23 B.C., and flourished in great splendour as the capital of Lusitania. In 713 it was taken by the Moors, who lost it to the Spaniards in 1229. Pop. 16,000.

Mérida, (1) capital of the Mexican state of Yucatán, is situated on a barren plain, 25 miles S. of Progreso, its port on the Gulf of Mexico, and 95 miles N.E. of Campeachy. It occupies the site of a former native city, and was founded by the Spaniards in 1542. Mérida has an old Franciscan convent, a cathedral, government and episcopal palaces, a university, seminary, girls’ high school, and conservatory of music, an antiquarian museum, a public library, hospital, &c. It is the centre of the henequen (sisal fibre) industry. Pop. 62,000.—(2) A town of Venezuela, 5290 feet above sea-level, at the foot of the Sierra Nevada de Mérida, 70 miles S. of the lake of Maracaibo. Founded in 1558, it was almost wholly destroyed by earthquakes in 1812 and 1894. It is the seat of a bishop, has a university and several higher schools, and manufactures of carpets and woollen and cotton stuffs. Pop. 14,000.

Meriden, a city of Connecticut, 19 miles by rail N. by E. of New Haven, with a number of manufactories of metal wares, cutlery, firearms, &c. Meriden contains the state reform school. Pop. (1880) 15,540; (1920) 29,867.

Meridian (Lat. *meridies*, ‘mid-day’), the name given to the great circle of the celestial sphere which passes through both poles of the heavens, and also through the zenith and nadir of any place on the earth’s surface. Places on the earth’s surface geographically N. or S. of one another lie under the same meridian circle, or in the same meridian

plane. The meridian is divided by the polar axis into two equal portions, which stretch from pole to pole, one on each side of the earth. It is mid-day at any place on the earth's surface when the centre of the sun comes upon the meridian of that place; at the same instant it is mid-day at all places under the same half of that meridian, and midnight at all places under the opposite half. All places under the same meridian have therefore the same longitude (see LATITUDE AND LONGITUDE, where the question of the First Meridian is discussed). Stars attain their greatest altitude when they come upon the meridian; the same thing is true approximately of the sun and planets; and as at this point the effect of refraction upon these bodies is at a minimum, and their apparent motion is also more uniform, astronomers prefer to make their observations when the body is on the meridian. The instruments used for this purpose are called *meridian circles*. See MURAL CIRCLE.

Meridian Measurement.—Two stations, having nearly the same longitude, are chosen; their latitude and longitude are accurately determined (the error of a second in latitude introduces a considerable error into the result), and the direction of the meridian to be measured ascertained; then a base line is measured with the greatest accuracy, as an error here generally becomes increased at every subsequent step; and then, by the method known as triangulation, the distance between the two stations, measured along the earth's surface, is ascertained. This corresponds to the length of the arc of the meridian contained between the parallels of latitude of the two stations. As the previously found latitudes of its two extremities give the number of degrees it contains, the average length, along the earth's surface, of a degree of this arc can be at once determined. This operation of meridian measurement has been performed at different times on a great many arcs lying between 68° N. lat. and 38° S. lat., and the results show a steady though irregular increase in the length of the degree of latitude as the latitude increases. On the supposition that this law of increase holds good to the poles, the length, along the earth's surface, of every tenth degree of latitude in English feet is as follows:

Degree of Latitude.	Length of Degree in English Feet.	Degree of Latitude.	Length of Degree in English Feet.
0°	362,732	50°	364,862
10°	362,843	60°	365,454
20°	363,158	70°	365,937
30°	363,641	80°	366,252
40°	364,233	90°	366,361

This result shows that the earth is not spherical, as in that case the length of all degrees of latitude would be alike, but of spheroidal form—its curvature becomes less as we go from the extremity of its greater or equatorial diameter to the pole. See EARTH.

Meridian, capital of Lauderdale county, Mississippi, 135 miles by rail N. by W. of Mobile. It has founding and machine-making industries, and manufactures of cotton, blinds and sashes, furniture, &c. Pop. (1900) 14,050; (1920) 23,399.

Mérimée, PROSPER, a great French writer, was born at Paris, 28th September 1803, the son of a well-known painter. He was educated at the Collège Charlemagne, and tried law, but soon abandoned it. He was in Spain during the revolution of 1830, and after his return became attached to the government, and held office successively in the ministry of Marine, of Commerce, and of the Interior, becoming finally Inspector of Historical Documents, in which capacity he visited the south and west of France, Auvergne, and Corsica. He had been long an intimate friend of the Countess Montijo, mother of the Empress Eugénie, and con-

sequently enjoyed the closest intimacy with the imperial family at the Tuileries, Compiègne, and Biarritz, yet without surrendering his independence of spirit and frankness of speech. Admitted to the Academy in 1844, he became a senator in 1853, and in 1858 president of the committee for reorganising the Bibliothèque Impériale. His last years were clouded by ill-health and melancholy, and the misfortunes of his country and the downfall of the imperial house hastened on his death, at Cannes, 23d September 1870.

Mérimée began his career as a writer at twenty-two by an audacious literary *espèglerie*, entitled *Théâtre de Clara Gazul*, a collection of Spanish plays of singular maturity, represented as translated by Joseph L'Estrange, with his own portrait in female dress as frontispiece. A volume of pretended translations of Illyrian folk-songs, by an imaginary Hyacinthe Maglanovitch, followed in 1827, under the title *Guzla*. His more important works embrace novels and short stories, archaeological and historical dissertations, and travels, all of which display wide and exact learning, keen observation, strong intellectual grasp, grave irony and real humour, and withal a style that attains an exquisiteness of perfection rare even among the best French writers. Ever the refined and elegant scholar, he wrote, rather than affected to write, as a dilettante—'le gentleman auteur' as he was styled by his own countrymen. Of his more erudite works it may here be enough to name his *Histoire de Don Pèdre I., Roi de Castille* (1848; Eng. trans. 1849); *Études d'Histoire Romaine* (1844); *Les faux Démétrius* (1852); *Monuments historiques* (1843); and *Mélanges historiques et littéraires* (1855). But his greatest work is his tales, about twenty in number, some of which are among the rarest masterpieces of the story-teller's art: *Colomba*, *Mateo Falcone*, *Carmen*, *La Vénus d'Ille*, *Lokis*, *Arsène Guillot*, *La Chambre Bleue*, and *L'Abbé Aubain*. One of the most remarkable merits of some of these stories, as *La Vénus d'Ille* and *Lokis*, is the dexterous manner in which an uncanny superstition is turned to artistic use.

Mérimée's character remains somewhat of an enigma, with its outward mask of cynicism, its inward capacity for the most tender and devoted friendship, its longing for the love of little children. In his constant struggle against impulse and enthusiasm he succeeded, but, as he himself says of Saint-Clair in the *Vase Etrusque*, the victory cost him dear. Few lives have been more solitary and unhappy than Mérimée's, at once from a paralyzing distrust of himself and of others, and from the constitutional melancholy of the sceptic to whom the world is only a series of incomprehensible and fleeting images, and who mistrusts life and death alike. He was one of the few men who have drawn their unbelief from mother and father alike. No great writer has left a more remarkable monument than the famous *Lettres à une Inconnue* (1873; Eng. trans., ed. Stoddard, New York, 1874), the revelation of a heart throughout an acquaintance, first of love, then of friendship, extending over thirty years. Here we find no selfish cynic, but a man gracious, affectionate, delicate, touched with poetry despite his scepticism, faithful and loyal unto death—his last words were written but two hours before the end. The unknown lady's actual existence has been questioned, and she has been identified with the Countess Lise Przedrerska, sister of the Marquis de Noailles, and with Mademoiselle J. F. Dacquín. What professed to be the 'inconnue's' letters in reply were published in 1888, but without any explanation being offered; an English translation of these followed in two volumes in 1889. Only less interesting than the first series are the *Lettres*

à une autre Inconnue (1875), and the *Lettres à Panizzi* (1881), full of lively gossip and clever criticism.

See the Studies by Tamisier (Mars. 1875), D'Haussonville (1888); also Tournoux (1879), Filon (1894, 1898), Pinvert (1906, 1911), Trahard (1925).

Merino (Span. 'an inspector of sheep-walks'), an important breed of Sheep (q.v.). See also WOOL.

Merioneth, a triangular county of Wales, with a maximum length and breadth of 45 and 30 miles, a seaboard of 38 miles, and an area of 660 sq. m., or 422,372 acres, is bounded on the N. by the counties of Carnarvon and Denbigh, E. and S. by Montgomeryshire and the river Dovey, and W. by Cardigan Bay. Pop. (1801) 27,506; (1841) 39,332; (1881) 52,038; (1921) 45,450. Cliffs or low sands skirt the coast, which at some distance out to sea is fringed by dangerous sandbanks. Inland, the surface, although nowhere attaining such an altitude as that of Carnarvonshire, is rugged and mountainous in the extreme, interspersed in places with picturesque valleys, lakes, and waterfalls. Aran Mowddu (2970 feet), Cader Idris (q.v., 2914), and Aran Benllyn (2902) are the highest peaks; Bala the largest lake; whilst of rivers the principal are the Dee, which flows north-east, and the Dovey and Mawddach, which reach the sea after a south-west course. The soil generally is poor and large tracts are unfit for profitable cultivation. There is much permanent pasture. Great numbers of sheep are bred, and flannels and woollens to some extent manufactured, but the principal wealth of the county arises from its mineral products. Slate and limestone are largely quarried, much manganese ore is produced, and from mines in the vicinity of Dolgelley and Bala some gold is obtained. Merioneth contains no parliamentary or municipal boroughs. It sends one representative to parliament. The principal towns are Bala, Barmouth, Corwen, Dolgelley, Festiniog, Harlech, and Towyn. Among Welsh counties Merioneth is singular in retaining in English its primitive British name. Its difficulty of access precluded it from figuring in the wars of early history. See work by A. Morris (1913).

Meristem, the formative tissue of plants, is distinguished from the permanent tissues by the power its cells have of dividing and forming new cells. Meristem forms the tissue of embryo plants, and of apex of stems and roots, and also the cambium-layer by whose division stems and roots grow in thickness.

Merivale, JOHN HERMAN, an English scholar and translator, was born at Exeter in 1779, the grandson of Samuel Merivale (1715-71), a worthy Presbyterian minister at Tavistock. He was sent to St John's College, Cambridge, and was called to the bar in 1805. He contributed largely to Bland's *Collections from the Greek Anthology* (1813), and brought out a second edition himself in 1833. From 1831 to his death in 1844 he held the office of Commissioner of Bankruptcy. Works of no little merit were his *Poems, Original and Translated* (1841), and *Minor Poems of Schiller* (1844).—CHARLES, son of the preceding, was born in 1808, and educated at Harrow, Haileybury, and St John's College, Cambridge, where he took his degree in 1830, and became in due course fellow and tutor. He was successively select preacher at Cambridge (1838-40) and at Whitehall (1839-41), Hulsean lecturer (1861), and Boyle lecturer (1864-65). From 1848 to 1869 rector of Lawford in Essex, he was chaplain to the Speaker from 1863 to 1869. He was dean of Ely from 1869 till his death, 26th December 1893. His *Fall of the Roman Republic* (1853) is a brilliant sketch,

marred by its over-indulgence to imperialism, the sole fault of his admirably learned and eloquent *History of the Roman Empire* (7 vols. 1850-62). Later books are *History of Rome* (1875), *Early Church History* (1879), and *Contrast between Pagan and Christian Society* (1880). See his *Autobiography and Letters* (1899).—Another son, HERMAN, born in 1806, was educated at Harrow and Trinity College, Oxford, elected Fellow of Balliol, called to the bar in 1832, and appointed professor of Political Economy at Oxford in 1837, and, later, permanent Under-secretary of State first for the colonies, next for India. In 1839 he was made C.B. He died on February 8, 1874.—His son, HERMAN CHARLES (1839-1906), was the author of a number of successful plays, including *Forget-Me-Not*, *The Butler and The Don*, and *The Master of Ravenswood*. Besides a novel, *Faucit of Balliol* (1882; in its stage form, *The Cynic*), he published *The White Pilgrim and other Poems* (1883), and other works. His *Stage and Bar* (1902) is an entertaining autobiography.

Merle D'Aubigné. See D'AUBIGNÉ.

Merlin, the name of an ancient British prophet and magician, who is supposed to have flourished during the decline of the native British power in its contest with the Saxon invaders. The prophetic child Ambrosius first mentioned by Nennius in his *Historia Britonum* was confounded with Ambrosius Aurelianus, the conqueror of Vortigern, and the resulting Merlin Emerys or Ambrosius appears in Geoffrey's later work in the new form of Merlin Silvestris or Caledonius. It is as the subject of one of the cycle of Arthurian romances that Merlin's name has survived. The Cambrian Merlin is said by Geoffrey of Monmouth, in his *Historia Britonum* and *Vita Merlini*, to have lived in the 5th century, to have sprung from the intercourse of a demon with a Welsh princess, to have been rescued from his malignant destiny by baptism, and to have displayed the possession of miraculous powers from infancy. The adventures of Merlin were taken, with additions from Armorican and other sources, from the Latin of Geoffrey, and made popular in the French language by Robert Wace and Robert de Borron. Henry Lonelich's English verse translation is in the library of Corpus Christi College, Cambridge. The analysis of the romance of Merlin in Ellis's *Specimens of Early English Metrical Romances* was made from the MS. in Lincoln's Inn Library. There is a MS. in the Scottish National Library, and one in Bishop Percy's folio MS. (printed in 1867). The prose romance is longer and more important than the metrical one. *Merlin, Roman en Prose du XIII^e Siècle*, was published by the Société des Anciens Textes Français in 1886, and the Early English Text Society published under the editorship of H. B. Wheatley in 1865-69, and in 1899, *Merlin, or the Early History of King Arthur about 1450-60*, printed from the MS. in the Cambridge University Library. Merlin is frequently alluded to by our older poets, especially by Spenser, and his story occupies a prominent position in Tennyson's *Idylls of the King*. A collection of prophecies attributed to Merlin appeared in French (Paris, 1498), in English (Lond. 1529 and 1533), and in Latin (Venice, 1554); and their existence is traceable at least as far back as the middle of the 14th century. The Strathclyde Merlin, called Merlin the Wylt, or Merlin Caledonius, once believed to be originally a different character, was placed in the 6th century, and considered a contemporary of St Kentigern, Bishop of Glasgow. His grave is still shown at Drummelzier on the Tweed, where, in attempting to escape across the river from a band of hostile rustics, he was impaled on a hidden stake. A metrical life of him

in Latin, extending to more than 1500 lines, professedly based on Armoric materials, and incorrectly ascribed to Geoffrey of Monmouth, was published by the Roxburghe Club in 1833. His prophecies—published at Edinburgh in 1615—contain those ascribed to the Welsh Merlin.

Merlin. See FALCON.

Mermaids and Mermen, in the popular folklore of Europe, a class of beings more or less like men, living in the sea, but in some circumstances capable of social relationships with men and women. The typical mermaid has the head and body of a lovely woman to the waist, ending in the tail of a fish with fins and scales. She has long and beautiful hair, and is often seen above the surface of the water, combing it with one hand while in the other she holds a mirror. She often discloses what is about to happen, and not seldom gives supernatural knowledge and powers to a favoured mortal—a thing in perfect keeping with primitive notions of sorcery, which easily attributed exceptional powers to beautiful women, as Lilith and Circe. Again, she sometimes exercises a special guardianship over an individual, and avenges his wrongs; but her relation to man most often brings with it disaster. There are many stories of mermaids who have fallen in love with men, or been detained through the possession of the skin which they had stripped to dance on the shore, and who have been faithful wives and mothers until they found an opportunity to return to the sea. And there are examples of the converse case of a mermaid falling in love with a man and enticing him to go and live with her under the sea, as well as of a merman bewitching and carrying off a mortal maiden.

Such are the principal forms of mermaid stories found everywhere, with more or less artistic elaboration. The Danish *Hafmand* or *Maremind*, the Irish *merrow* or *merruach*, the Breton *Marie-Morgan*, the Russian *rusalka* or stream-fairy and *vodyany* or water-sprite, some forms of the Teutonic *nixies*, and the enchanting Sirens of classical mythology have all close affinities with each other in the dangers they bring to men, the beauty and joyousness of their lives, and yet the gloom of sadness that overhangs them. In their malignant aspect they touch the general doctrine of Demonology (q.v.), and may be explained on an animistic theory of its origin. To the beauty of the conception and the elaborations of which it is capable in the popular imagination we owe some of the loveliest of our folk-tales as well as such delightful artistic tales as *Undine* and many fine poems of the ages of literary culture. One of the most detailed stories of this class is that of Melusine (q.v.). The mermaid had a firm hold of the imagination of our fathers. One caught at Edam in 1403 was carried to Haarlem, learned to spin, and showed a becoming reverence for the cross. See Baring-Gould's *Popular Myths of the Middle Ages*.

Mermaid's Purse, the popular name of the egg-case of the skate or other cartilaginous fish.—*Mermaid's Gloves* is a common British sponge, *Chalina oculata*.

Meroë, capital of Ethiopia (q.v.) after the fall of Napata, stood on the east bank of the Nile near where Shendi now is. Excavations since 1902 have laid bare streets, temples, houses, an observatory, tombs, reliefs, inscriptions, pottery, bronzes, traces of extensive iron-workings, pottery kilns, and remains of wharves and landing-stages on the river, indicating vast manufacturing industry and trade. Within the city proper a royal city, a vast enclosure surrounded by a magnificent wall of cut stone, has also been revealed; in the palaces treasures of gold and of ornaments have been found, while

the royal baths admirably illustrate the character of the Meroitic arts. By the excavations at Meroë knowledge of Ethiopia has been greatly advanced. See works by Crowfoot (1911) and Garstang (1911).

Merovingians, or **MERWINGS**, the first dynasty of Frankish kings in Gaul. The name is derived from Merwig or Merovech, king of the western or Salian Franks from 448 to 457. His grandson Clovis (q.v.) established the fortunes of the dynasty, which gave way to the Carolingians (q.v.) in 752. See FRANCE, FRANKS.

Merrick, LEONARD, novelist, short story writer, and dramatist, was born in London in 1864. For a time he worked in South Africa in a diamond mine and then in a solicitor's office, and later became an actor—born Miller, he legally adopted his stage name 'Merrick' in 1898—and actor-manager. In 1889 he gave up the stage for literature, thereafter producing numerous writings as *The Actor-Manager* (novel), *Whispers about Women* (short stories), *The Man who Understood Women* (short stories), *When the Lamps are Lighted* (play). A collected edition of his works with prefatory tributes by leading novelists and dramatists appeared in 1918. Never greatly popular with the public, his literary skill is, however, much admired by other writers.

Merrimac, a river rising among the White Mountains of New Hampshire, flowing south into Massachusetts, and falling into the Atlantic Ocean near Newburyport after a course of 150 miles. It has numerous falls, affording immense water-power. The principal manufacturing towns on its banks are Manchester, Nashua, and Concord in New Hampshire, and Lowell and Lawrence in Massachusetts. It is navigable to Haverhill.

Merriman, HENRY SETON (pseudonym of Hugh Stowell Scott), English novelist, was born in 1863. For some years he was in business, but in 1892 definitely turned to literature. *The Sowers* (1896) was his first success, and outstanding among later novels were *Roden's Corner* (1898), *In Kedar's Tents* (1897), *The Isle of Unrest* (1899), *The Velvet Glove* (1901), *The Vultures* (1902), *Barlasch of the Guard* (1903), *The Last Hope* (1904). His novels are notable for construction and for excellence of plot. He died in 1903.

Merseburg, a town of Prussian Saxony, on the Saale, 8 miles S. of Halle. Its Domkirche is a four-towered pile, with Romanesque choir (1042), transept (circa 1274), and 16th-century nave—the whole restored in 1884–86. The organ (1666) has 4000 pipes; and there is a very early bronze effigy in low relief of Rudolph of Swabia, who here was defeated and slain by Henry IV. in 1080. The castle, a picturesque edifice, mostly of the 15th century, was once the bishop's palace, and afterwards (1656–1738) the residence of the dukes of Sachsen-Merseburg. Beer, iron, paper, celluloid, and machinery are manufactured. Pop. 23,000. Henry the Fowler in 934 gained his great victory over the Hungarians near Merseburg, which suffered much in the Peasants' War and in the Thirty Years' War.

Mersenne, MARIN, a constant friend of Descartes, was born in 1588, and died at Paris in 1648. He was a fellow-student of Descartes at the Jesuit college of La Flèche, and took the habit of a Minim Friar in 1611; his life thereafter was spent in study, teaching in convent-schools, and travel. He did valiant battle with numerous clerical controversialists on behalf of the orthodoxy of the philosophy of Descartes, and wrote vigorously against atheists and other unbelievers. His profound knowledge of mathematics is seen in a number of books, and in his *Harmonie Universelle*

(1636), an invaluable contribution to the science of music.

Mersey, an important river of England, separates, in its lower course, the counties of Chester and Lancaster, and has its origin in the junction of the Etherow and Goyt, on the borders of Derbyshire, east of Stockport. It flows in a west-south-west direction, and is joined on the right by the Irwell 6 miles below Manchester, from where it was made navigable to Liverpool for large vessels in the year 1720, and has had great influence on the subsequent progress of the two towns. Besides the Irwell the chief affluents are the Bollin and the Weaver from Cheshire. At its junction with the Weaver the Mersey expands into an estuary about 16 miles long and from 1 to 3 miles broad; opposite Liverpool it is a mile and a quarter in width, with a considerable depth at low-water. On its Cheshire side is the entrance to the Manchester Ship-canal. The estuary is much obstructed by sandbanks, but the excellent system of pilotage in practice, combined with the skilful and admirable construction of the sea-walls, renders the navigation comparatively secure. A railway tunnel connecting Liverpool and Birkenhead has been in successful operation since 1886. A road tunnel is projected. The alluvial meadows on the banks of the Mersey are famous for their fertility, and many thousands of acres of the most valuable land in the two counties have been reclaimed. The basin of the Mersey extends over an area of 1706 sq. m., which includes the larger portion of Lancashire and Cheshire; length including estuary 70 miles.

Merthyr-Tydfil or **Tydfil** (so called from the martyrdom here of a Welsh princess of that name), a parliamentary and county borough of South Wales, on the confines of the counties of Glamorgan and Brecknock, 24 miles N. by W. of Cardiff, its port, and 178 W. of London. Pop. (1801) 7705; (1921) 80,116. Surrounded by lofty and bleak hills, the town stands on the banks of the river Taff, and is partly built on slag foundations, the refuse of mines in the vicinity. Its streets are for the most part narrow and irregularly built, and the public buildings of little architectural interest, but since the formation of a local board of health in 1850 great improvements have been effected in the widening of thoroughfares, water-supply, and sewage-works: previously epidemics of great severity were frequent. The board of health became an urban district council in 1894. The town, with Dowlais, Penydarren, and other outlying districts, was made a county borough in 1908. The sole industries, upon which the whole population is more or less directly dependent, arise from the numerous collieries and iron and steel works in the vicinity; Merthyr being the centre of the Glamorganshire coalfield, and as such having excellent railway communication with all parts. With Aberdare it is noted for the excellence of its steam coal, and the quantity of iron and steel annually turned out from the great works of Dowlais, Cyfarthfa, and Plymouth is enormous. In 1816, and again in 1831, the town was the scene of severe riots, on the latter occasion the disturbance not being quelled by the military without a loss of twenty-three lives. The parliamentary borough comprises two divisions, Merthyr-Tydfil, which is coterminous with the borough, and Aberdare, comprising the parishes of Aberdare and Llanwono, each having one member.

Merton and Morden, an urban district of Surrey, 10 miles SW. of London, on the Wandle, has several factories. Only fragments remain of the Augustinian priory (1115) in which the parliament met which passed, in 1235, the Statute of

Merton (see **LEGITIMATION**). Here were educated Thomas Becket and Walter de Merton, Bishop of Rochester and Chancellor, who in 1264 founded Merton College, at Oxford. The church is mainly of the same date as the priory. Pop. 17,500.

Meru, in Hindu Mythology, a fabulous mountain in the centre of the world, 80,000 leagues high. It is the most sacred of all mythical mountains, and the abode of Vishnu.

Meru, LAKE. See **MOERO**.

Merv, a oasis of Turkestan (Turkoman Republic) between Bokhara and the north-eastern corner of Persia, 512 miles by rail (1886) from the Caspian, and 118 from the Oxus. Sixty miles long by 40 broad, it is watered by the Murghab; grows wheat, sugar, grass, cotton, and silk; has a hot, dry climate; and is inhabited by about 150,000 Tekke Turkomans. The site of Old Merv at Bairam-Ali is covered with ruins far and wide. Thirteen miles off, across the Murghab, a small Russian town has grown up. The men are clever workers in silver, and breed horses, camels, and sheep; the women weave silk and make carpets. Merv or Mouru is mentioned in the *Zend Avesta*. There Alexander the Great built a town. The oasis was held successively by the Parthians and the Arabs, who made the city of Merv capital of Khorassan. It was the seat of a Nestorian archbishop in the 5th century, and of a Greek archbishop in the 14th; and in the 8th it was the headquarters of Mokanna (q.v.), the 'Veiled Prophet of Khorassan.' Under the Seljuk Turks Merv enjoyed its period of greatest splendour, especially under Sultan Alp Arslan. It began to fall into ruin after being taken and sacked by the Mongols in 1221. From the Uzbeks it passed in 1510 to the Persians, who lost it in 1787 to the emir of Bokhara. In 1856 the Turkomans made themselves masters of the oasis; but they in turn submitted to the Russians in 1883. The great dam for irrigation purposes at Sultanbend, destroyed in 1784, was restored in 1909. Merv occupies an important strategic position at the intersection of the routes Bokhara-Meshhed and Khiva-Herat. A railway from Merv runs up the Murghab valley to Kushk (200 m.) near the Afghan frontier. See **TURKESTAN, ASIA (CENTRAL)**.

Méryon, CHARLES, etcher, was born at Paris, the son of an English physician, in 1821. Leaving the navy, he devoted himself to art, but despite undoubted genius and great technical skill, he found little appreciation in his own day, and died insane at Charenton Asylum, 13th February 1868. His sombre and imaginative etchings of streets and buildings in Paris are now very highly esteemed. See books by Wedmore (1879) and Bouvenne (1883), Burty's monograph (trans. 1879) and Stokes's (1905).

Mesa. See **NEW MEXICO**.

Mescal, a Mexican intoxicant prepared from Agave (q.v.), opens a paradise of colour, leaving the judgment clear.

Mesdag, HENDRIK WILLEM (1831-1915), 'the painter of the North Sea,' born at Groningen, was one of the best of marine painters. Specially famous were his 'Sunrise on the Shores of Holland' and 'The Return of the Fishing Boat.' See monograph by Zilcken (trans. 1896).

Mesembriaceæ, **FICOIDEÆ**, or **AIZOACEÆ**, an order of archichlamydeous dicotyledons, comprising succulent shrubs, herbaceous perennials and annuals with opposite leaves, often of fantastic shape; in the 18 genera are over 400 species, mainly belonging to Mesembrianthemum. They are inhabitants of warm regions chiefly, especially the Cape and the South Sea Islands. The typical genus is also the most important in regard to utility and beauty. It furnishes the Ice Plant (q.v.) of our

gardens, and many other beautiful and curious species are to be met with in our greenhouses. *M. nodiflorum* is employed in the manufacture of Morocco leather, and furnishes abundance of alkali. The Kou of the Hottentots is *M. anatomicum*, the roots, stems, and leaves of which they collect and beat and twist together, and then ferment, for the purpose of chewing to allay thirst. If chewed immediately after fermentation it is narcotic and intoxicating. It is the Canna Root of the South Africans. The Hottentot's Fig (*M. edule*) is abundant on the sandy plains of the Cape of Good Hope, and the fruit and leaves are eaten. The fruit of *M. equilateratum* is named Pigs'-faces in Australia, and is eaten by the natives; that of *M. geniculiflorum* is ground into flour in Africa and made into bread, as is that of the Ice Plant. The Flower of Crete is the seed-vessel of *M. Tripolium*, which in the rainy season expands in the form of a star, allowing the seeds to escape. The name should be spelled Mesembriaceæ, as it is from the Greek *mesēmbria*, 'mid-day,' because the flowers bloom usually at mid-day. See MIMICRY.

Mesentery (Gr. *meson*, 'middle;' *enteron*, 'intestine') is the broad fold of peritoneum (the great serous membrane of the abdomen) which attaches the intestines (strictly the small intestine; for special names have been given to the corresponding structure in connection with the different parts of the large intestine) posteriorly to the vertebral column. It serves to retain the intestines in their place, while it at the same time allows the necessary amount of movement, and it contains between its layers the blood-vessels and nerves which pass to them, the lacteal vessels, and mesenteric glands. These glands are 100 to 150 in number, and are about the size of an almond or smaller. The only disease of any importance affecting these glands is Tubercle (q.v.), which, when extensively developed in them, is sometimes called *tabes mesenterica*. See also ANEMONE (SEA).

Meshhed ('the place of martyrdom,' also spelt *Meshed* and *Mashhad*), the principal city of north-eastern Persia, the capital of Khorasan, and the centre of important trade routes. The city stands on a tributary of the Hari-Rud, 460 miles E. by N. from Teheran, 230 N.W. of Herat, and has a beautiful appearance when seen from a distance. Above the walls, which are of great circuit, shine the gilded dome and minarets of one of the most splendid mosques of the East, that built above the tomb of Imâm Riza, a follower of Ali, and the eighth imâm of the Shiite sect. Meshhed is the sacred city of the Shiites, and is held in as much veneration by them as Mecca is by the Sunnite Moslems; it is visited every year by over 50,000 pilgrims. The city is bisected by a wide tree-shaded street, down the middle of which flows a muddy current between low stone walls. It has another handsome mosque, and several colleges and caravanserais. The people make excellent felt-rugs, carpets, swords, turquoise jewellery, velvet, and cotton and silk goods. Cotton, wool, opium, dried fruits, turquoises are exported to Russia, India (*via* Nushki), and Afghanistan. The Transcaspian Railway gives Russia the predominance in trade with Meshhed. The transit trade has declined. The fixed population is about 80,000. Owing to its elevated situation (3055 feet) the city has a cold winter; the summer temperature ranges from 76° to 106° F. Fourteen miles NNW. are the ruins of Tus, the old capital of Khorasan, where Firdausi and Haroun-al-Raschid were buried.

Meskoutin, or HAMMAM MESKOUTIN ('the Accursed Baths'), a place in Algeria, 48 miles (77 by rail) E. by N. of Constantine, with remarkable hot baths (203° F.), known to the Romans as *Aquæ Tibilitinae*. They and the adjoining ferruginous and sulphureous springs (170°) are still used medicinally. The incrustations of carbonate of lime and clouds of steam, &c. give the region a very singular appearance.

Mesmer, FRIEDRICH ANTON or FRANZ (1734-1815), the founder of the doctrine of Animal Magnetism (q.v.), was born near Constance. He was bred for the priesthood at Dillingen and Ingolstadt, but took up the study of medicine at Vienna, and took his doctor's degree in 1766 with a treatise *De planetarum influxu*. About 1772 he began with a Jesuit, Hell, to investigate the curative powers of the magnet, and was led to adopt the opinion that there exists a power, similar to magnetism, which exercises an extraordinary influence on the human body. This he called animal magnetism, and published an account of his discovery, and of its medicinal value, in 1775. In 1778 he went to Paris, where he created a great sensation. His system obtained the support of members of the medical profession, as well as of others; but he refused an offer of an annual pension of 20,000 livres (about £800) to reveal his secret; and this, combined with other circumstances, gave rise to suspicion, and induced the government in 1785 to appoint a commission, composed of physicians and scientists (Bailly, Franklin, Lavoisier, &c.), whose report was unfavourable to him. He now fell into disrepute, and, after a visit to England, retired to Meersburg, in Switzerland, where he spent the rest of his life in complete obscurity.

See Lives by Kerner (1859) and P. A. Graham (1890); Podmore's *Mesmerism and Christian Science* (1909); and HYPNOTISM.

Mesoderm. See EMBRYOLOGY.

Mesolonghi. See MISSOLOGHI.

Mesopotamia ('between the rivers'), the district between the Tigris and Euphrates, from the foot of the Armenian mountains to near Bagdad. The name (loosely applied to the old vilayets of Mosul, Bagdad, and Basra) is the Greek equivalent of the old Aramaic (Syrian) Aram-Naharaim, and became current after Alexander's Asiatic conquests; the Arabs call the district El-Jezira ('the island'). Mesopotamia proper (55,000 sq. m.) is level, and falls from an altitude of 1100 feet in the north-west to 160 feet in the south-east, where the alluvial region of Babylonia begins. The soil is sandy, but when well watered or, as it was in ancient times, well irrigated, it develops extraordinary fertility. Yet after the Turks (Seljuks) made themselves masters of the region (1515) it fell more and more a prey to barrenness and neglect. Having been in the possession successively of the Assyrians, Babylonians, Persians, Greeks, Romans, Arabs, Turks, and British, and many a time and oft the battle-ground between the armies of these mighty empires, its records are full of stirring events and great changes and vicissitudes. See ASSYRIA, BABYLONIA, IRAQ, EUPHRATES, and TIGRIS, and articles on the various ancient cities.

Mesozoa, a term applied by Van Beneden to a few very simple organisms which he regarded as intermediate between Protozoa (unicellulars) and Metazoa (multicellular animals). This may well be, but it is probable that some are simplified as the result of parasitism. There are various types—e.g. Dicyemids, parasitic in cuttle-fishes; and Orthonectids, parasitic in Turbellarians, in Brittle-stars, and in Nemerteans.

Mesozoic (Gr., 'middle-life'), a term introduced

by Professor Phillips to designate the group of geological systems, the fossil remains of which differ equally from those of the Palæozoic ('ancient-life') and Cainozoic ('newer-life') eras. It is synonymous with the term Secondary, and includes the Triassic, Jurassic, and Cretaceous systems.

Mesquite. See MEZQUITE.

Mess (Fr. *metts*, Old Fr. *mes*, Ital. *messò*, 'a dish,' from Lat. *missum*, 'sent,' or 'served up') originally signified a dish or portion of food. In the British army and navy the men are divided into 'messes' of whatever number is most convenient for taking their meals together. In the army each man, unless married, or for other reasons allowed to live out of mess, pays a daily rate to his mess for the provision of extras above the Government Ration (q.v.), which is managed by a non-commissioned officer under the supervision of an officer. *Sergeants' Messes* are run like a club, managed by one of themselves under a committee of sergeants supervised by an officer, the adjutant if possible. *Officers' Messes* are very similar, but on a larger scale. All officers also pay a monthly subscription towards keeping up the mess establishment, such as furniture, liveries, wages of servants, table-linen, &c. The affairs of the mess are managed by a committee of officers presided over by the senior member.

In the British navy there are on the large ships various messes. The 'ward-room,' which includes all officers from sub-lieutenant to captain (who messes by himself); the 'gun-room, the junior rank of officers; and the warrant-officers' mess. On small ships ward-room and gun-room are joined.

Messenger, ANDRÉ CHARLES PROSPER, born at Montluçon in 1853, was a pupil of Saint-Saëns, and had produced two operettas and a ballet when his comic opera *La Basoche* (1890) made him popular in London as well as at home; followed by *Madame Chrysanthème*, *Mirette*, *Les Petites Michus*, and *Véronique* (1898).

Messala, or MESSALLA, a cognomen adopted from the relief of Messana (Messina) in the Roman war with the Carthaginians in Sicily in 263 B.C. by the consul Marcus Valerius Maximus Corvinus. The most famous of the family was Marcus Valerius Maximus Corvinus Messala, who fought on the republican side at Philippi in B.C. 42, but, pardoned by the triumvirs, became one of the generals and friends of the Emperor Augustus. He was intimate with Horace and Tibullus, encouraged Ovid, and was a conspicuous patron of literature and art. He was an accomplished (if affected) orator, and wrote historical works as well as poems in Latin and in Greek; but none of his works have been preserved.

Messalina, VALERIA, the daughter of Marcus Valerius Messala Barbatus, and wife of the Roman emperor Claudius (q.v.), a woman infamous for her avarice, her lust, and her atrocious cruelty. Taking advantage of the weakness and stupidity of the emperor, she played the harlot without restraint, and murdered all who murmured at her gilded shame. The best blood of Rome flowed at her pleasure; among her victims were the daughters of Germanicus and Drusus, Justus Catonius, M. Vinicius, Valerius Asiaticus, and her confederate Polybius. During a temporary absence of the emperor she went so far in open shamelessness as publicly to marry C. Silius, one of her favourites. The blinded emperor's eyes were at last opened by his freedman Narcissus, and he was persuaded to give orders for her execution. She was put to death by Euodus, a tribune of the guards, in the gardens of Lucullus, 48 A.D.

Messapians, an ancient race inhabiting the

heel of Italy, possibly identical with the Iapygians; Calabria being also called in ancient times Messapia and Iapygia. The Messapians were of the Indo-European stock, possibly originally from Illyria (see ITALY, in the section on Ethnology); of their language some fifty brief inscriptions only remain.

Messenger-at-Arms, in Scots Law, an officer appointed by and under the control of the Lyon-King-of-Arms (see HERALD), employed to execute summonses civil and criminal, in connection with the Court of Session and the Court of Justiciary.

Messengers, KING'S, in the home service carry letters and despatch-boxes from and to the palace, or between various officials. On a much higher footing stand the Foreign Service Messengers, who convey despatches to and from his Majesty's embassies and legations abroad and the Foreign Office. They are usually of good social standing, and are nominated by the Secretary of State for Foreign Affairs only after passing a qualifying examination in modern languages, arithmetic, horsemanship, and other relevant accomplishments.

Messenia, in ancient Greece, the western of the three peninsulas that project southwards from the Peloponnesus, bounded on the E. by Laconia, and on the N. by Arcadia and Elis. Composed chiefly of fertile plains, separated by mountain-chains and watered by the Pamisus and other streams, it yielded abundant corn and wine. The original Pelasgic inhabitants were conquered by the Dorians, but soon absorbed their conquerors and rose to great prosperity. This excited the envy of the Spartans, who waged two long wars (743-724 and 685-668) against the brave Messenians. Most of those who survived the second war emigrated to Sicily, where they took possession of Zancle, and changed its name to Messana, the present Messina. Those who submitted to Sparta were made helots; but they revolted and waged a third war of ten years' duration (from 464). The survivors settled in Naupaktos. After the battle of Leuctra (370) Epaminondas invited the descendants of the Messenians back to Greece, and they joyfully responded to his invitation; for them he founded the new capital, Messene. Their independence continued till the Roman conquest in 146 B.C. Messenia is the name of a nomarchy of the modern kingdom of Greece, producing currants, figs, oil, and wine.

Messiah (Heb. *Mashia'h*, equivalent to the Greek *Christos*, 'Anointed'), in the Old Testament, the great Deliverer and Saviour, whom the Jews expected to be sent by God, not only to restore their country to the power and splendour of the days of David, but even, by compelling the Gentiles to acknowledge the supremacy of the theocratic people, to raise it to the summit of universal dominion. See CHRIST, JESUS, JEWS, BAR-COCHBA, SABBATAI ZEVI, ANSARS, ISMAÏLIS, and MAHDI; and the articles in *Hastings's Dictionary of the Bible* and *Dictionary of Christ and the Gospels*, and in the *Jewish Encyclopædia*.

Messina, the second city of Sicily, stands on the western shore of the strait of the same name, 110 miles E. by N. of Palermo, and 195 SSE. of Naples. The city occupies a narrow strip of coast between the harbour and the hills behind; the opposite or eastern side of the harbour is formed by a sickle-shaped tongue of rock, that only leaves a narrow entrance on the north. Although a very ancient city, Messina possesses few antique buildings or remains. The destructive hands of enemies, and the still more destructive agency of earthquakes, are responsible for this. The greater part of the city was laid out, regularly, with handsome houses after the earthquake of 1783. The cathedral was begun by Count Roger the Norman in 1098, but had been almost wholly rebuilt when it

was destroyed in 1908. It had a gorgeous high-altar and *baldachino*, and a venerated treasure in a reputed letter of the Virgin to the townsmen; and, like the churches of St Gregory and St Nicholas, was adorned with magnificent mosaics. The citadel was built by Charles II. of Spain in 1680, the Gonzaga Castle in 1540, and another castle in 1547-57. The city was destroyed, along with Reggio and other towns in Calabria and Sicily, by the great earthquake of the 28th December 1908, by which, according to an official estimate, over 77,000 lives were lost. Messina is an archbishop's see. Industry is confined chiefly to muslin, linen, and silk goods, the working of coral, and the preparation of fruit essences. Messina is among the principal Italian ports. The exports embrace principally fruits and their manufactured products, such as wine, essences, citrate of lime, olive-oil, seeds. Pop. (1921) 176,405.

Founded in 732 B.C. by the people of Cumæ, the place was first called *Zancle* (i.e. a sickle), and through the commercial enterprise of its people rapidly grew in prosperity. In 495 Anaxilas of Rhegium seized the town and changed its name to *Messana* (Messene). The Carthaginians conquered it and destroyed it in 396, and in 288 it fell into the hands of the Mamertines, who again changed its name to *Mamertina*. The intestinal quarrels of these people gave occasion to the outbreak of the Punic war between Carthage and Rome, on the conclusion of which (241 B.C.) the city became Roman, and in 535 A.D. passed to the Eastern Empire. The Saracens took the city in the 9th century, and were only expelled in the 11th century by the Normans. Here the Sicilian Vespers' massacre raged in 1282, and from that year down to 1713 Messina belonged to Spain. The people revolted in 1671 and were backed up by France, but were reduced to submission in 1678, and at the same time deprived of their privileges of self-government. Then in 1743 the plague, and forty years later an earthquake, came to complete the ruin of the city. It was, moreover, bombarded by the Neapolitans in 1848, and in 1861 it was the last place in Sicily to yield to the Sardinian (Italian) troops. The province of Messina has an area of 1254 sq. m., and a pop. (1921) of 582,064.

Messina, STRAIT OF (Lat. *Mamertinum fretum*, or *Fretum Siculum*), separates Italy from Sicily, is 24 miles in length, and varies from 2½ to 14 miles in breadth. Since 1879 a scheme for making a railway tunnel under the strait has been under discussion. See SCYLLA AND CHARYBDIS.

Meštrović, IVAN, Croat sculptor, born in 1883 in northern Dalmatia, a peasant's son, kept sheep as a boy, was taught wood-carving by his father, was apprenticed to a marble-cutter at Spalato, and studied sculpture at Vienna. He designed the Serb national temple for Korsovo. Always direct and simple, he works in many mediums, and in all of them shows consummate mastery. His statuary is architectural, and springs from the crude heart of Slavonia.

Metabolism, a general term for the chemical changes of living matter. See FUNCTION, PHYSIOLOGY (VEGETABLE), PROTOPLASM.

Metacentre. See HYDROSTATICS.

Metallography is an important branch of metallurgy, dealing with the microscopic examination of the structure of metals and alloys. Dr Sorby of Sheffield, the founder of the science of petrology, applied his methods to the study of iron, and developed the technique of the preparation of microscopic sections in 1864. A few years later Martens, working independently, examined many specimens of cast iron and steel. Little progress

was thereafter made until Osmond, between 1883 and 1894, published his researches on carbon steels, which stimulated interest in the subject to such an extent that microscopic examination is now as indispensable as chemical analysis in every metallurgical laboratory.

A convenient size for a metallic microsection is about ½ inch in diameter by ¼ inch in thickness. It is first filed or ground to a smooth surface, then rubbed upon emery-paper of three or four grades of increasing fineness. The final polish is given on a rotating disc covered with polishing cloth, which is damped and well rubbed with a finely divided abrasive, such as alumina or rouge. After this treatment the specimen should show a mirror-like surface, without any trace of scratches. The structure must then be developed by treatment with liquid etching reagents. These are generally of an acid character, chosen on account of their selective chemical action on the separate micrographic constituents. Hydrochloric acid is used for white metals, nitric and picric acids for iron and steel, acid ferric chloride for bronzes, ammonia for brasses. As metals are opaque even in very thin slices, it is necessary to examine the specimen by reflected light. A beam of light is introduced into the microscope tube above the objective, and falls upon a thin microscopic cover-glass set at an angle of 45° to the optical axis. Part of the light is reflected downwards through the objective, falls upon the specimen, and is reflected back through the objective and cover-glass to the eye-piece. The structural constituents which have been attacked by the etchant then appear darker or coloured, while the remainder of the surface is unaffected. The structure and properties of an alloy vary with its composition, heat treatment, and mechanical treatment. Composition only can be determined by chemical analysis. The microscope decides as to the structural suitability of an alloy for its destined commercial use, and in investigating causes of breakage or failure it is indispensable to the modern metallurgist.

See Desch, *Metallography*; Guillet and Portevin, *Metallography and Macrography*.

Metallurgy is a word of Greek derivation, and signifies 'metal working.'

(1) ANCIENT METALLURGY.—As the advance of civilisation in every age may be measured by the progress of metallurgy, the subject is of extreme interest from the ethnological point of view.

The first metals used by man were gold, silver, and copper, as these are found in nature in the metallic state. The earliest metal users were probably the ancient Egyptians, who were extremely expert in fashioning delicate gold jewellery and gold and silver vessels of various kinds. Gold ornaments found in Egyptian tombs have been ascribed to a period 7000 B.C. In the time of Rameses II. (1330 B.C.) the mines of Nubia are said to have yielded gold to the value of £125,000,000 per annum, and we find it stated in the Old Testament that 'silver was not any thing accounted of in the days of Solomon' (1000 B.C.).

In western Asia archaeologists have unearthed vases, goblets, jugs, and ornaments of silver of beautiful workmanship belonging to a period 3000-2000 B.C., the analyses of which indicate that the process of cupellation was then known.

For the manufacture of tools and weapons copper was, in most cases, probably the first metal employed, as copper is harder than the precious metals, and can be made much harder by hammering. In Egypt and Mesopotamia pure copper preceded bronze; copper may have been used in Egypt as early as 8000 B.C. The oldest copper mine known was in the Sinai peninsula, where copper was produced

during the 1st Dynasty (5600–5300 B.C.). After that mine was exhausted copper is said to have been brought from Cyprus, from which the metal derives its name. In Egyptian tombs, copper axes and chisels of this period are frequent, while harpoons, fish-hooks, needles, and other objects have been found of a much earlier date. Similar objects of later origin have been discovered in Mesopotamia.

The earliest Egyptian implements were hammered into shape, casting being unknown. This was also the case in the Lake Superior district, where numerous knives, axe-heads, and ornaments of copper bearing the marks of hammers, show that the North Americans were unacquainted with the process of melting and casting. Casting probably began in Egypt about 5600 B.C. During the period of the 2d Dynasty (5300–5000 B.C.) beautiful vessels were cast in copper and bronze, the metal of which is not more than $\frac{1}{8}$ inch thick.

Bronze is an alloy of copper and tin, and would have been discovered by smelting an ore containing both of these metals. This must have been the case in Britain, where native copper was not found. Copper and tin ores were smelted in Cornwall, and in Roman and earlier times large quantities of tin were exported to the continent of Europe for bronze-making, hence the Bronze Age in Britain (2000 B.C.) was not preceded by a copper age. The results of researches in lake-dwellings indicate that in Europe copper was used for a short period before bronze. In the European Bronze Age gold is seldom met with. Metallurgical appliances, such as large anvils, moulds, and crucibles, show that casting was well known, and slag scoriae and furnace refuse furnish evidences of the practice of smelting.

The smelting process was undoubtedly discovered by a primitive man who built up his wood fire with lumps of ore instead of stone. Among the ashes he found a piece of reduced metal, which had the property of malleability, and could be fashioned into any shape by hammering. From this the first metallurgical furnace was evolved, consisting merely of a hole in the ground in which ore and fuel were heated together. If an iron ore, such as hematite, were used, malleable iron would have been obtained, which could be easily forged at a red heat. Iron-making is still carried on in almost as primitive a fashion in Africa and India, and in the Catalan forge of the Pyrenees.

The earliest record of iron in Egypt is the discovery of some iron beads dating from 6000 B.C., but these were in all likelihood made from meteoric iron, as iron appears to have been first used for making weapons about 4000 B.C. It is not known definitely when and where iron smelting originated, but it was certainly practised in Africa and India in very early times, and was introduced into Europe from the East about 1300–1000 B.C. In prehistoric and early historic times there was an important trade in Indian steel between India and the coasts of Arabia and the Red Sea; the steel smiths of Persia were also celebrated for the manufacture of swords.

If the translations from the Hebrew words in the Old Testament are correct, the Jews were acquainted with six metals—gold, silver, copper, iron, lead, and tin. In the book of Job we find one of the first metallurgical references: 'Surely there is a vein (a mine) for the silver, and a place for gold where they fine it. Iron is taken out of the earth, and brass is molten out of the stone.'

In Greek and Roman times considerable progress was made in metallurgy, especially in the production of iron. The Romans were familiar with the smelting of lead, and used the metal for making, among other things, baths, water-pipes, and writing tablets. Soldering with lead, or a lead-tin alloy,

was also well known, as well as the purifying of silver and gold by fusion with lead. Large quantities were taken from Britain, where many pigs of lead have been discovered bearing the names of various Roman emperors. Tin and mercury were also prepared in quantity and used for many industrial purposes.

The first descriptions of metallurgical processes are found in the *Naturalis Historia* of Pliny the Elder, who collected at the beginning of the Christian era all the information available at that time about metals.

During the next 1500 years metallurgical progress was slow; iron mines were worked in Asia Minor, Spain, Gaul, and Britain, and in the 7th century in Bohemia and Saxony. In 1530 a general treatise, *De Re Metallica*, was written in Venice by Agricola, which marks the beginning of a new period of systematic metallurgy. He has been called 'the father of metallurgy,' and some of his processes have undergone little material change up to the present day. Between the 16th and 18th centuries zinc, antimony (though Flinders Petrie says this metal was known to the ancient Egyptians), bismuth, arsenic, manganese, platinum, nickel, and cobalt were discovered; the remaining metals are products of the 19th century.

See Gowland in *Journal of Royal Anthropological Institute*, xlii. p. 235–287; Flinders Petrie, *Tools and Weapons*, and articles in *Ancient Egypt*; Lavard's researches in Mesopotamia; Munro's *Lake-dwellings of Europe*.

(2) MODERN METALLURGY.—The term metallurgy, in its modern sense, includes the extraction of metals from their ores, the further refining and treatment required to fit them for their commercial uses, the mixing of metals to produce alloys, and the study of the structures of metals and alloys as revealed by the microscope and the X-rays (see METALLOGRAPHY). A few of the noble metals, such as platinum, gold, silver, and occasionally copper and mercury, are found in the metallic state. Other metals occur in nature, mainly in combination with oxygen as oxides, with sulphur as sulphides, with oxygen and carbon dioxide as carbonates, and with oxygen and silica as silicates. These metallic compounds are generally associated with a quantity of useless earthy material or gangue, the mixture being known as an ore. The first step in the extraction of a metal is to get rid of as much as possible of this worthless gangue, which would tend to choke up furnaces, and by absorbing heat cause a waste of fuel. For this purpose concentration methods are employed, which generally depend on the difference in specific gravity between the metal and the gangue. The usual modern methods are in this order—hand-picking, magnetic separation, jigs, shaking tables, froth flotation. See ORE-DRESSING. After concentration, sulphide ores are roasted to drive off sulphur either partially or completely; in the latter case the metallic oxide is left, and the ore is said to be dead roasted. The sulphur dioxide produced may be used for the manufacture of sulphuric acid. Carbonate ores are also calcined to get rid of carbon dioxide. If the smelting furnaces are at a considerable distance, calcination is preferably carried out at the mine, as the ore loses weight in the process, and thus freight costs are reduced. The roasting furnace is usually of the reverberatory type. It may be 6 feet long, 16 feet broad, and 3 feet high between bed and roof. At one end is the fire grate, the flame from which sweeps over the hearth, drawn by the chimney draught at the other end. Multiple hearth and muffle furnaces are also frequently used. Generally speaking, the product obtained from the roasters consists of impure metallic oxide. Copper and nickel

sulphides are not dead roasted, and the roasted ores contain both oxide and sulphide. The next step is the reduction of the oxide to metal in the smelting furnace. This may be of the vertical shaft type, like the iron blast-furnace, or it may be of similar design to the reverberatory roasting furnace. The latter is coming more into favour in modern practice, as the universally used concentration processes produce a large quantity of *finer*, which would choke up a shaft furnace and render it unworkable. The charge of a smelter consists of ore, fuel, and flux. The fuel, which may be either coal or coke, serves two purposes. By its combustion it provides the heat necessary to promote the chemical reactions, and it supplies the reducing agents required to abstract oxygen from the metallic oxide and set free the metal. Carbon at high temperatures readily unites with oxygen, the first stage of its combustion producing carbon monoxide. This compound has still a strong affinity for oxygen, and owing to its gaseous state can come into more intimate contact with the ore particles than the solid carbon. Carbon monoxide is thus the chief reducing agent in the smelting process. Although the ore has probably been concentrated it still contains gangue, and to remove this a flux is required. For metallurgical purposes we may divide oxides into two classes, basic oxides and acidic oxides. An acidic oxide can unite with a basic oxide, but combination does not generally take place between oxides of the same class. If, then, the gangue is mainly of a siliceous nature containing the acid oxide silica, a basic flux like limestone is required. If the gangue is basic, an acid or siliceous flux is needed. At the high temperature of the furnace the flux forms a molten compound with the gangue known as slag. The molten metal trickles down the furnace, forming a pool at the base, and on top of it floats the lighter slag, protecting it from oxidation. The smelting process, of course, varies considerably in detail with the kind of ore under treatment. The metal may be obtained in the liquid state and poured into moulds, or, as in the case of zinc and mercury, as a metallic vapour, which is then condensed. Cinnabar or mercuric sulphide simply requires the application of heat to set the metal free. From some sulphide ores, for example, galena or lead sulphide and cinnabar, the metal may be liberated by smelting with a flux containing iron, which combines with the sulphur, forming sulphide of iron. The product obtained by smelting copper and nickel sulphide ores is not pure copper or nickel, but a compound known as matte. The further treatment of matte is carried out in a Bessemer converter, and consists in blowing air through the molten metal to oxidise the impurities, which are then eliminated either in the gaseous state or in the slag. The Bessemer converter is also used in producing steel from pig-iron. See IRON AND STEEL.

The foregoing are a few typical examples of what may be called pyrometallurgical processes, but in addition to these hydrometallurgical processes are in common use.

These depend on the solubility of the metallic part of an ore in liquids such as water, sulphuric acid, solutions of chlorine and potassium cyanide. The ore is finely crushed and leached with the solvent with continuous agitation. From the solution thus obtained the metal may be recovered by electrolysis, or precipitated by the addition of some cheaper metal which can displace it. For example, gold is precipitated from cyanide solutions by metallic zinc, copper and silver from their solutions by iron. Metallic solvents are also used. Silver ores are treated with molten lead or smelted with lead ore; the silver dissolves in the lead, and

can be recovered by suitable methods. Mercury is employed in the extraction of gold and silver on account of its power of dissolving these metals, forming alloys known as amalgams.

An important modern development in metallurgy is the great extension of the use of electro-metallurgical methods. The electric arc furnace is used for smelting and refining, and contains carbon electrodes suspended either vertically or obliquely over the bath. The current forms an arc between the electrode and the charge, passes through the ore or metal, and either forms another arc with a second suspended electrode or goes to an electrode in the base of the furnace. A temperature of over 3000° C. can be attained. In steel-making the arc furnace can produce a pure metal of easily controlled composition from impure materials. Electrolytic processes have also a wide application. The production of the useful metal aluminium has been made a commercial possibility only by the use of the electric current. The metals magnesium, calcium, potassium, and sodium are exclusively prepared by electrolysis of their fused salts, and many metals, such as copper and zinc, can be obtained by electrolytic methods in a state of purity not attained by other means. The commercial success of this branch of metallurgy depends, of course, upon the cost of current, so that electro-metallurgical processes tend to concentrate in places like Norway, Niagara, and Kinlochleven and Foyers in Scotland, where water-power is available.

The progress of metallurgy in late years has been, perhaps, as much along the lines of improving and cheapening established processes as discovering new methods. Great attention has been paid to the scientific designing of furnaces, to more efficient methods of firing, and to heat conservation. Firing by oil and by powdered coal are coming increasingly into use. Fuel oil is vaporised or atomised, mixed with air, and sprayed into the hot furnace; coal is pulverised to pass a 200-mesh sieve, carried upon an air-blast into the furnace and burnt. These methods of firing are clean, smokeless, and easily regulated; they give perfect combustion, develop the full heating-power of the fuel, and reduce labour costs. Some types of metallurgical furnaces are heated by producer-gas, the regenerative system being employed. By this method the hot gases which are the products of combustion pre-heat the incoming gas and air, the result being a considerable saving of fuel.

See Gowland, *Metallurgy of Non-ferrous Metals*; Hofman, *General Metallurgy*; Schnabel and Louis, *Metallurgy*; Turner, *Metallurgy of Iron*.

Metal Mountains. See ERZGEBIRGE.

Metals.—The chemical elements are frequently divided into metals and non-metals, but it is impossible to make a sharp distinction between the two classes.

A metal may be defined chemically as an element which can replace hydrogen in acids to form a series of salts. Metals unite with oxygen to form basic and sometimes acidic oxides, functioning in the former as metals, and in the latter as non-metals. There are also amphoteric oxides, which may be either basic or acidic, and in these the same element plays a metallic or a non-metallic part according to circumstances.

There are certain physical properties, however, which are generally associated with the term 'metal,' such as 'metallic lustre,' high specific gravity, high melting-point, malleability, ductility, and conductivity, though these properties are also shared by some of the non-metallic elements. All metals when freshly cut or polished show a characteristic lustre, and are good reflectors of light. In many cases

the bright surface becomes quickly dulled by the formation of a film of oxide. The brilliancy of a newly cut piece of lead, for example, soon tarnishes on exposure to air, and silver, though it does not oxidise, becomes blackened by the sulphuretted hydrogen found as an impurity in the atmosphere. Those metals which have little attraction for oxygen, and retain their brightness in pure air, are sometimes called the 'noble' metals. Iridium, rhodium, platinum, gold, silver, mercury, and a few others belong to this class, and are found in nature in the metallic state. Polished metals have, in most cases, a silvery appearance, some have a slight bluish tinge, gold is yellow in colour, copper is reddish-yellow, and bismuth is faintly pink. When viewed in thin films by transmitted light, however, gold appears green, or, if the film be very thin, blue; silver also appears blue. A suspension of minute particles of gold in water or in glass—a colloidal solution—appears of a ruby colour by transmitted light. Many metals again which can take a brilliant polish are dull or black when finely powdered, owing to almost complete absorption of light and consequent loss of reflecting power. High specific gravity is also a characteristic of the more commonly used metals; it ranges from 6·8 for antimony to 21·4 for platinum. A notable exception is aluminium, sp. gr. 2·7. Lithium, sodium, and potassium, the uses of which on account of their softness and liability to oxidation, are mainly chemical, are the lightest metals, and float upon water. These and other metals which have a density not exceeding 4 are sometimes known as the 'light metals,' those above 4 being classified as the 'heavy metals.' Mercury and gallium are the only metals which are liquid at ordinary temperatures; the melting-point of mercury is -39°C . Tungsten has the highest known melting-point, variously estimated at about 3000°C . The most useful physical properties of the metals are perhaps those of malleability and ductility, which permit of their being rolled or forged to the required size or shape, beaten into leaf, or drawn into wires. Gold possesses these properties in the highest degree; gold leaf can be obtained $\frac{1}{100000}$ of an inch in thickness, and a single grain can be extended to a wire 500 feet long. Other metals again, such as bismuth and antimony, are non-malleable, and are so brittle that they can be powdered in a mortar.

Metals required for engineering purposes are subjected to mechanical tests; the chief of which are measurements of tensile strength and hardness. The former is measured by pulling asunder a test-piece of standard size in a testing machine; the greatest stress it can bear up to the point of rupture is stated in pounds or tons per square inch of its cross-section. The tensile strength of antimony is only 1000 lb., of aluminium 20,000 lb., of copper from 30,000 to 60,000 lb.; nickel-chrome alloy engineering steel can be made to bear a stress of 100 tons, and steel piano wire may stand up to 200 tons per square inch. Metallic hardness is generally measured by Brinell's method. A hardened steel ball is forced into the surface of the metal to be tested, and the depth of the indentation measured. Some comparative numbers are: lead 1·0, tin 2·5, zinc 7·5, copper 12, soft iron 14·5, mild steel 24, hardened steel 93.

The metals excel the non-metals in another useful property, namely electrical conductivity. Silver is the best conductor, and is used as a standard; but copper, on account of its comparative cheapness and non-corrosive properties, is universally employed for commercial purposes. Aluminium, although its weight for the same conductivity is half that of copper, has certain practical disadvantages, such as difficulty of making

joints and liability to corrosion, which hinder its usefulness. Metals used as conductors must be pure, as the addition of a small quantity of another metal frequently increases the resistance considerably. As little as one part in a thousand of bismuth destroys the usefulness of copper for electrical purposes.

The structure of metals is crystalline in character. When a solution of a crystalline substance, such as sugar or salt, is evaporated slowly, well-formed crystals may often be obtained of a definite geometrical shape which depends on the crystalline habit of the substance. During the solidification of a molten metal crystallisation begins at the surface and at points within the liquid, but the individual crystals are not free to assume their characteristic form, as their growth is hindered by the pressure of their neighbours. The air surfaces of ingots of lead, tin, aluminium, and antimony show beautiful fern or star-like patterns, and the 'spangled' appearance of galvanised iron is due to the large crystal grains of the zinc coating. Most of the metals may be assigned to three crystalline systems, the cubic, the hexagonal, and the tetragonal. Magnesium, cadmium, zinc, antimony, and bismuth belong to the hexagonal, and tin to the tetragonal system. The individual crystal grains are again built up of atoms, which have no definite orientation as long as the metal is in a state of fusion, but at the moment of crystallisation the atoms arrange themselves in a regular geometrical pattern known as a space-lattice. See CRYSTALLOGRAPHY.

By means of the X-rays the internal structure of metals has been carefully investigated, and the metals belonging to the cubic system have been found to form two kinds of cubic space-lattice. In one variety, the 'centred' cubic space-lattice, there is an atom at each corner, and one in the centre of the cube. In the other, the 'face-centred' cubic space-lattice, there is an atom at each corner, and one in the centre of each face. This space-lattice is continuous. The metals lithium, sodium, chromium, iron, molybdenum, and tungsten form a 'centred' cubic space-lattice. Aluminium, copper, silver, gold, platinum, cobalt, and nickel have their atoms arranged in a 'face-centred' cubic space-lattice.

Metal-work. Sculpture (q.v.) being separately treated, the present article deals with other kinds of artistic metal-work. Since man gained the power of working metals he has produced more or less artistic examples of work in this medium. In Assyria, Egypt, Greece, &c., many pieces remain to show the excellence of the taste and the power of craftsmanship of the ancient peoples. Of mediæval gold and silver work one of the most renowned objects is the altar in the church of St Ambrose at Milan. It was executed by Wolvinus (9th century), and contains figures in relief of Christ and the Apostles with ornamental borders in enamel. Another very fine work in gold and enamel is the *Pala d'Oro* (altar front) of St Mark's, Venice, by Byzantine artists of the 10th or 11th century. The shrine of the Magi in Cologne Cathedral is a magnificent reliquary of the 12th century, in which the figures are of gold and the architectural decorations covered with enamels and precious stones. Many specimens of ecclesiastical gold and silver work of the 13th century remain. Of 14th-century examples the splendid silver reliquary in the church of Orvieto, by Ugolino of Siena, is very remarkable. Two very fine examples of middle-age work are the altars of St James, Pistoia, and of the Baptistery of St John at Florence, both in silver; begun in the 14th century, their execution occupied 150 years. Some of the greatest artists in Italy in the 14th and 15th

centuries practised the goldsmith's art, including Lucca della Robbia, Ghiberti, Brunelleschi, Donatello, and Jacopo della Quercia. In the 16th century Cellini's is the greatest name. There are some very artistic productions in pewter by the French artist François Briot (16th cent.).

Many fine works have been executed in bronze; Stanracius of Constantinople cast in the 11th century the bronze gates of St Paul's-without-the-Walls at Rome, destroyed in 1823, but of which drawings exist. A century later Barisanus made the fine bronze door of the cathedral of Monreale in Sicily. There is a great 13th-century candelabrum in Milan Cathedral, 15 feet high. The east door of the Baptistery at Florence, upon which Ghiberti was engaged from 1425 to 1452, is considered a marvellous work of art. Another door in this building, by A. Pisano, completed in 1430, after being in progress for twenty years, is also an admirable production. P. Vischer's shrine of St Sebald at Nuremberg is a beautiful monument which, though quite different in form from the objects named above, resembles them in the design being an intimate combination of small works in sculpture and architectural ornament. A fountain in the Maximilian-strasse, Augsburg, executed by H. Gerhard in 1593, has been much admired. For want of space we can only name two more bronzists—B. Morel, who did the great candelabrum in Seville Cathedral, and L. Bernini, who in the 17th century executed many clever works in Italy.

There is perhaps no class of metal objects in which artistic skill is more marvellously displayed than in some of the rich suits of armour made in the end of the 15th, but chiefly in the 16th century. These are for the most part of iron or steel, with ornament in *repoussé* or engraved; sometimes with both combined, and occasionally with damascening in gold and silver. Among those who practised the armourer's art in Italy the most famous names are Michelagnolo, Filippo Negrolo, Romero, and some members of the Piccinini family. In Germany Kollman of Augsburg, and in France Antoine Jacquard stood high. Some of the finest suits of armour made at this period are in the Museum of Arms at Dresden, and in the Louvre and Musée d'Artillerie, Paris.

Wrought-iron work, rude but effective, appears on the wooden doors of some Romanesque churches of the 12th century. In the 13th and 14th centuries the work in this metal became more refined, and among admirable examples of the latter period may be mentioned the screens round the tombs of the Scala family at Verona, and a screen in the church of Santa Croce, Florence. Screens, grilles, and other objects with open wrought-iron ornament, beautifully designed, and ranging over a period from the 13th to the 16th century, but especially those made during the 15th and 16th, are found in many churches in Germany, Spain, France, and England. In the latter country the early grille over Queen Eleanor's tomb, Westminster, and the later screen to Edward IV.'s at Windsor are fine examples; so also are the still later (18th century) railing-panels made for Hampton Court Palace by Huntington Shaw. The canopy of a draw-well at Antwerp by Quentin Matsys is one of the best works of its kind in hammered iron. Many of the elaborately chiselled iron locks and hinges made at Nuremberg and Augsburg in the 15th and 16th centuries are wonderfully beautiful. The National Museum at Munich is especially rich in specimens of these.

With these examples of work produced in Europe must also be remembered certain work from the East. From early times Persian and Damascus (see DAMASCENE) metal work has reached

a high standard, more especially in pierced and gilt brass. The inlay of the class where black enamel is let into silver is famous. Indian metal work is more ornate, and in large was especially connected with religion, though much of the hammered work is of undoubted merit. It is to Japan, and more especially China, however, that one must go for work which for artistic genius stands unrivalled in the world. Incense burners, bowls, boxes, and metal work of all descriptions have been produced in many metals, more especially in bronze, in the working of which alloy the Chinese craftsman excelled. In conjunction with enamels they produced the famous *cloisonné* work, where delicate bronze or gold metal work is overlaid and inlaid with the enamel. Modern metal work has been sadly commercialised, but many schools have sprung up over the world where good art work is being produced.

See Digby-Wyatt, *Metal-work* (1852); the South Kensington Museum *Catalogue of Bronzes*, by Fortnum, and of *Gold and Silversmith's Work*, by J. H. Pollen; Hefner-Alteneck, *Serrurerie* (1870); Plon's *Cellini* (1883); French works by Garnier (1859) and Codron (1901); German by Raschdorff (1878) and Haas (1902); English by Jackson (1903), Miller (1903), Woodworth (1903), Twopenny (1904), Pearson (1904), and Hasluck (1904).

Metamorphosis, a term applied in ancient mythology to the frequent transformation of human beings into beasts, stones, trees, and even into fire, water, or the like, which are essential parts of popular folklore everywhere. These metamorphoses afforded a subject to Greek poets and writers of the Alexandrine period, and to Ovid among the Romans. See BEAST-FABLES and FOLKLORE.—In Zoology the term Metamorphosis is applied to such marked changes as those from caterpillar to insect, or from tadpole to frog, where the young form or larva is strikingly different from the adult. See the articles on Amphibia, Caterpillar, Crustacea, Echinoderms, Frog, Insects, &c.; and for Metamorphosis in Botany, see MORPHOLOGY and FLOWER.—In Geology the term *metamorphism* is applied to the alteration undergone by rocks under heat, pressure, and other influences, so that they assume a crystalline or semi-crystalline structure. See GEOLOGY, GNEISS, PETROGRAPHY, SCHIST.

Metaphor (Gr. *metaphora*, 'a transference'), a figure of speech by means of which one thing is put for another which it only resembles. Thus, the Psalmist speaks of God's law as being 'a light to his feet and a lamp to his path.' The metaphor is therefore a kind of comparison implied but not formally expressed, in which the speaker or writer, casting aside the circumlocution of the ordinary similitude, seeks to attain his end at once, by boldly identifying his illustration with the thing illustrated. It is thus of necessity, when well conceived and expressed, graphic and striking in the highest degree, and has been a favourite figure with poets and orators, and the makers of proverbs, in all ages. Even in ordinary language the meanings of words are in great part metaphors; as when we speak of an *acute* intellect, or a *bold* promontory. The metaphor is false if the simile involved cannot be intelligibly evolved from it; and, to avoid what are often called *mixed* metaphors, it is well that the implicit simile should be conceived objectively, as in a picture. Such cases of confusion as Motley's 'The crozier went hand-in-hand with the battle-axe' are obvious enough, but most often the *mixed* metaphor is wrapped up in a cloud of rhetoric, as in De Quincey's sentence: 'The very recognition of these or any of them by the jurisprudence of a nation is a *mortal wound* to the very *keystone* upon which the whole vast arch of morality reposes.' Ruskin in his *Præterita*, describing Rogers's cold

reception of him as a boy, says: 'The cultivation of *germinating* genius was never held by Mr Rogers to be an industry altogether delectable to genius in its zenith.'

Metaphysical Poets, a term applied by Dr Johnson in his life of Cowley to the group of which Donne is the most outstanding example. They were men of learning, and to show their learning was their whole endeavour; they neither copied nature nor life, hence their thoughts are often new but seldom natural; the most heterogeneous ideas are yoked by violence together, nature and art being ransacked for illustrations, comparisons, and allusions; they failed, as might have been expected, in moving the affections or attaining the sublime, but what they wanted they endeavoured to supply by hyperbole—their amplifications had no limits, they left not only reason but fancy behind them, and produced combinations of confused magnificence that not only could not be credited but could not be imagined. Yet, if they frequently threw away their wit upon false conceits, they likewise sometimes struck out unexpected truth: if their conceits were far-fetched, they were often worth the carriage. Such is Johnson's explanation of the phrase and its meaning, and it must be admitted that the name is to a certain extent appropriate enough, for the philosophising and analytic spirit pervades the works of the whole school, and intellect rather than emotion is ever the stuff out of which their phantasies are framed. Their constant weakness is the tendency towards conceits and similes that are merely fantastic and ingenious, which mars a modern reader's pleasure in almost every poem of Donne and Cowley.

Metaphysics, a word first applied to a certain group of the philosophical dissertations of Aristotle, containing what Aristotle (q.v.) called 'first philosophy,' and Plato 'dialectics.' The phrase *meta ta physika* means probably 'the books after the physics,' but has been interpreted 'the matters above or beyond physics.' The branch of philosophy so called is the highest department, and deals with speculative questions as to the nature and limit of human consciousness and the possibility of establishing truths beyond empirical consciousness. The term has been sometimes used, as by Mansel, to comprise Psychology along with metaphysics proper or Ontology. See PHILOSOPHY.

Metaphyta, many-celled plants, in contrast to the single-celled Protophytes.

Metastasio, the Greek form of the surname of PIETRO TRAPASSI, an Italian poet, who was born of humble parents at Rome, on 6th January 1698. A precocious boy, he improvised verses and recited them to crowds on the street. This gift gained him a patron in his ninth year, one Gravina, a celebrated Roman lawyer, who educated him, and on his death (1718) left him his fortune. In 1722 Metastasio wrote his first libretto at Naples, which so charmed the great Roman singer Bulgarini, called La Romanina, that she took him into her house, and launched him on his successful career as a writer of opera-libretti—libretti which possess some real poetic qualities. These dramas, all with classical subjects, were set to music by some of the greatest composers then living, as Pergolese, Scarlatti, Durante, Hasse, Paisiello, Marcello, and others, and sung by some of the greatest singers who have ever lived, Farinelli and Caffariello. In 1729 Metastasio was appointed court-poet to the theatre at Vienna, for which he wrote several of his best pieces. His reputation spread rapidly and stood high throughout Europe, but from 1825 to 1865 his name was anathema in Italy. He died in Vienna on 12th April 1782, having for nearly forty years suffered from 'mental and moral ennui.'

His Letters were edited by Carducci (Bol. 1883). See Vernon Lee's *Studies of 18th Century in Italy* (1907), and Lives by Burney (1796) and Mussafia (1882).

Metaurus, a river of Central Italy, emptying into the Adriatic, on whose banks the Romans defeated the Carthaginians in 207 B.C.

Metayer System. See LAND LAWS.

Metazoa, many-celled animals, in contrast to the single-celled Protozoa (q.v.).

Metcalf, JOHN (1717–1810), 'Blind Jack of Knareborough,' lost his eyesight at six, but, tall and vigorous, fought at Falkirk and Culloden, smuggled, drove a stage-coach, and from 1765 took to road-making with great success.

Metcalfe, CHARLES THEOPHILUS, LORD (1785–1846), Indian and colonial administrator, born at Calcutta, was made a peer in 1845. See Life by Kaye (new ed. 1858).

Metchnikoff, ELIAS (1845–1916), Russian naturalist, born in Kharkoff govt., became professor at Odessa, and assisted and succeeded Pasteur at his Institute in Paris. His epoch-making memoir on the intracellular digestion of invertebrates (1884) led to his theory that wandering amoeboid cells attack and ingest or absorb useless or septic parts of the body, and that inflammation in vertebrates is the struggle between those microbe-eaters or phagocytes—the white or amoeboid blood corpuscles—and the disease-germs. He wrote a notable book on immunity (1903). See Life by his widow (trans. 1921).

Metellus, a plebeian family which rose to front rank in the Roman nobility. One member of it, Quintus Cæcilius Metellus Numidicus, twice defeated Jugurtha (109 B.C.); another, Quintus Cæcilius Metellus Creticus, conquered Crete (97 B.C.).

Metemmelh, or MATAMMA, a small town on the Nile opposite Shendy.

Metempsychosis. See TRANSMIGRATION.

Meteora, a group of four monasteries (formerly fourteen) planted on the summits of lofty rock-pinnacles on the northern side of the Peneus valley in Thessaly, 20 miles N.E. of Trikala. At a height of from 100 to 300 feet, they are accessible by breakneck ladders or by nets hauled up by windlasses.

Meteorology (Gr. *meteōra*, 'meteors, or atmospheric phenomena') was originally applied to the consideration of all appearances in the sky, both astronomical and atmospheric; but the term is now confined to that department of physics which treats of the phenomena of the atmosphere as regards weather and climate. Owing to the complexity of the phenomena, meteorology is the most difficult and involved of the sciences, and may seem, at first sight, almost incapable of being reduced to a science at all. On this account, the only procedure admissible in the first place is a faithful recording of facts by long and patient observation.

From the nature of the subjects which make up the science, it may be inferred that they occupied men's minds from a remote antiquity. From the time spent in the open air in the early ages, and from the imperfect protection afforded against the inclemency of the seasons, those appearances which experience proved to precede a change of weather would be eagerly recorded and handed down. In this way many valuable facts were ascertained and passed current from hand to hand; and perhaps there is no science of which more of the leading facts and inferences have been from so early a period incorporated into popular language. Aristotle was the first who collected, in his work *On Meteors*, the current prognostics of the weather. Some of these were derived from the Egyptians,

while a considerable number were the result of his own observation. Theophrastus, one of Aristotle's pupils, classified the opinions commonly received regarding the weather under four heads—viz. the prognostics of rain, of wind, of storm, and of fine weather. The subject was discussed only in its popular and practical bearings, and no attempt was made to explain phenomena whose occurrence appeared so irregular and capricious; but still the treatise of Theophrastus contains about all that was known down to comparatively recent times. No real progress was made till instruments were invented for making observations with regard to the temperature, the pressure, the humidity, the purity, and the electricity of the air. The discovery of the weight or pressure of the atmosphere made by Torricelli in 1643 was undoubtedly the first step in the progress of meteorology to the rank of a science. As this memorable discovery discloses what passes in the more elevated regions of the atmosphere, it follows that the elevations and depressions of the barometric column largely extend our knowledge of the subject. Indeed, nearly all of the more important of the discoveries of modern meteorology have been made through the barometric observations.

The invention and gradual perfecting of the thermometer in the same century formed another capital advance; as without it nothing beyond vague impressions could be obtained regarding temperature, the most important of all the elements of climate. Fahrenheit constructed small and portable thermometers, which, being carried by medical men and travellers over every part of the world, furnished observations of the most valuable description. By such observations alone the comparative temperature of different countries became known, and the exaggerated accounts of travellers with regard to extreme heat and cold were reduced to their proper significance. Scarcely less important was the introduction of the hygrometer, first systematically used by De Saussure (died 1799), and subsequently improved by Dalton, Daniell, August, and Regnault. From the period of the invention of these instruments the number of meteorological observers greatly increased, and a large body of well-authenticated facts of real value was collected. The climates of particular parts of the earth were approximately determined, and the science made great and rapid advances by the investigations into the laws which regulate the changes of atmospheric phenomena.

The theory of the trade-winds was first propounded by George Hadley in the *Philosophical Transactions* for 1735; and it may be mentioned as a remarkable fact that for about half a century it remained unnoticed, and then was independently arrived at by Dalton. The publication of Dalton's *Meteorological Essays*, in 1793, marks an epoch in meteorology. It is the first instance of the principles of science being brought to bear on the explanation of the intricate phenomena of the atmosphere. The idea that vapour is an independent elastic fluid, and that all elastic fluids, whether alone or mixed, exist independently; the great principles of motion of the atmosphere; the theory of winds, their effect on the barometer, and their relation to temperature and rain; observations on the height of clouds, on thunder, and on meteors; and the relations of magnetism and the aurora borealis—these are some of the important questions discussed in these remarkable essays, with singular acuteness, fullness, and breadth of view.

One of the most interesting and fruitful subjects of inquiry that engaged the attention of meteorologists was dew. The observations on this subject were first collected and reduced by Dr Wells, and the theory he advanced, supplemented by the later

researches of Dr John Aitken, gives a complete explanation of the phenomenon (see DEW).

In 1823 Daniell published his *Meteorological Essays and Observations*, which, while adding largely to our knowledge in almost every department of the subject, are chiefly valuable as bearing on the hygrometry of the atmosphere. Though the practical advantages which he anticipated to flow from it have not been realised, yet this difficult department of meteorology still stands indebted to him perhaps more than to any other physicist. The law of the diffusion of vapour through the air, its influence on the barometric pressure, and its relations to the other constituents of the atmosphere are among the least satisfactorily determined questions in meteorology.

It was until the 20th century assumed that the temperature of the air diminished with height up to the highest regions of the Atmosphere (q.v.), but in 1901 Teisserenc de Bort, with the sounding-balloons sent up from his observatory at Trappes near Paris, made the discovery that above a height of 6 miles the temperature remained constant with elevation, and in some cases rose with altitude. This upper region has been called the *stratosphere*; the lower region, where temperature diminishes with altitude, the *troposphere*. The lower surface of the stratosphere varies in the British Isles from 5 to 7 miles above sea-level. In equatorial regions it lies at a height of from 9 to 10 miles, and in the polar regions over the Arctic Ocean in lat. 75° N. descends to 4½ miles. Study of the thermal structure of the atmosphere owes much to Mr W. H. Dines and Sir Napier Shaw. While the causes of cyclones and anticyclones, important in their bearings on the weather, continue undetermined, a definite relationship between stratosphere and troposphere has been shown to exist under cyclonic and anticyclonic conditions. Of knowledge of the upper air generally the measure has been greatly increased as an almost necessary outcome of the development of aviation.

Electrical observations have been, of all meteorological observations, perhaps the least productive of results advancing the science, partly owing to their scantiness, and from the expense and trouble attending them.

Humboldt's treatise on *Isothermal Lines* (1817) constitutes a notable epoch in practical meteorology. Dové and, after him, Dr Buchan continued the investigation, and charts were given of the world, showing the temperature for each month and for the year. In 1868 another series of important charts was published by Dr Buchan, showing, by isobaric lines, the distribution of the mass of the earth's atmosphere, and by arrows the prevailing winds over the globe for the months and the year. These charts, later revised by him, and published in one of the *Challenger* reports, show the movements of the atmosphere and their immediate cause. It is thus seen that the prevailing winds are the simple result of the relative distribution of the mass of the earth's atmosphere; or that the direction and force of the prevailing winds are simply the flow of the air from a region of higher towards a region of lower pressure, or from where there is surplus to where there is a deficiency of air. On this broad and vital principle meteorology rests, and it is of universal application throughout the science in explanation not only of prevailing winds, but of all winds, and of weather and weather changes generally. Further, it supplies the key to the climatologies of the globe; for climate is determined by the temperature and moisture of the air, and these in their turn by the prevailing winds. In 1882 Loomis and in 1901 Herbertson published maps showing the rainfall of the globe. These maps and others that

have been constructed for separate countries show that the rainfall is everywhere determined by the prevailing winds, considered with respect to the regions from which they have immediately come, and the physical configuration and temperature of the part of the earth's surface over which they blow. The highest rainfalls are precipitated by winds which, having traversed a large breadth of ocean, come up against and blow over a high ridge lying across their path; and the amount is still further increased if the winds pass at the same time into regions the temperature of which constantly becomes colder. Of this the winter rains of north-western Europe and the summer rains of Japan are good examples. On the other hand, the rainfall is very small, or *nil*, where the prevailing winds have not previously traversed some extent of ocean, but have crossed a high ridge and now advance into lower latitudes, or into regions the temperature of which is markedly higher. Good examples of this are the summer rains of California and adjoining regions, and those of the Indus valley.

The establishment of meteorological societies during the last half of the 19th century must also be commemorated as contributing in a high degree to the solid advancement of the science which, more than any other, must depend on extensive and carefully conducted observation. A special object of meteorological societies is to ascertain the degrees of temperature and moisture in various localities, and the usual periods of their occurrence, together with their effects on the health of the people and upon the different agricultural products; so that, by a knowledge of the laws by which the growth of such products is regulated, it may be ascertained with some degree of certainty whether any given article can be profitably cultivated. But perhaps none of the arts have benefited to so large an extent by the results arrived at by meteorologists as navigation. The knowledge thus acquired of the prevailing winds over the different parts of the earth during the different seasons of the year, the regions of storms and calms, and the laws of storms has both saved innumerable lives, and, by pointing out the most expeditious routes to be followed, shortened voyages to a remarkable degree. In this department the name of Maury (q.v.) deserves special commendation.

Another fruit of the multiplication of meteorological stations is the prediction of storms and 'forecasts' of weather, first suggested in the United States about the middle of the 19th century. As regards the British Islands these 'forecasts' are based on information received every morning from the Atlantic, and from a network of selected stations in Great Britain and Ireland, and on the Continent, which give the exact state of the barometer, thermometer, hygrometer, and rain-gauge, with the direction and force of the wind, and appearance of the sky, at each of these stations at eight in the morning. In the event of there being any storm or other atmospheric disturbance at one or more of these places, a full and accurate description of it is thus conveyed to London; and it is the duty of the officials there to consider the direction in which the storm is moving and is likely to move, so as to enable them to give warning of its approach at different ports by special signals. But in addition to warnings of storms, daily 'forecasts' of the weather likely to occur in the different districts of Great Britain for the following two days are also issued. Long-range forecasts—some for a period of a month have been given—must in the present state of knowledge be considered as no more than guesswork. As regards storms the problem to be practically worked out is this: Given information showing the exact

meteorological conditions prevailing over the area embraced by the stations, with indications of a storm approaching in a certain direction, to determine, not the probable area over which the tempest will sweep, but the precise localities which will altogether escape, the places where the storm will rage, its continuance, its violence, and the particular directions from which the wind will blow at places visited by the storm. Weather-registers extending over long periods give no countenance to the notion that there are regularly recurring cycles of weather on which prediction sufficiently precise and particular to be of service to agriculture and navigation may be based. The manner in which good and bad seasons occur in different places with respect to each other shows clearly that they have little *direct immediate* dependence on any of the heavenly bodies, but that they depend directly on terrestrial causes. Owing to its proximity to the Atlantic, Great Britain is not so favourably situated for the issue of warnings as the countries of Europe to the eastward; but now the extension of the telegraph cable to the Faeroe Islands and Iceland, and wireless reports from vessels in the Atlantic, and also from Spitsbergen, have contributed to improve markedly the accuracy of weather forecasts. While this improvement is of general application, it is shown more particularly in the ability of the forecaster to predict the advent of storms, which formerly, coming without warning from the Arctic Ocean down the North Sea, not infrequently caused great fishing disasters on our northern and eastern coasts.

The study of meteorology has benefited largely by the establishment of high-level meteorological stations in the United States, Europe, India, Australia, and many other countries. The nine arctic expeditions in 1882-83, and antarctic expeditions of later years, devoted themselves largely to meteorological observations. In the Antarctic Scott's expedition (1910-13) yielded valuable results (see a publication in the meteorological work of the expedition by G. C. Simpson, 1919). Many first-class meteorological observatories are now established at which hourly observations are made.

On the diurnal phenomena the more important principles of the science are based. Of the sun's rays which arrive at the earth's surface, those which fall on the land are wholly absorbed by the thin surface layer, the temperature of which consequently rises. A wave of heat is thence propagated downward through the soil, the intensity of which rapidly lessens with the depth at a rate depending on the conductivity of the soil, till at a depth of about 4 feet it ceases to be measurable. Part of the heat of this surface layer is conveyed upwards into the atmosphere by convection currents. But as regards the surface of the ocean the case is totally different. Here comparatively little of the heat is arrested at the surface, but it penetrates, as shown by the observations of the *Challenger* expedition, to a depth of about 500 feet. Hence in deep waters the temperature of the surface is but little heated by the direct rays of the sun, though in shallow waters, owing to the heating of the bottom, the water has a considerable daily range of temperature. Thus, in mid-ocean, from 30° N. lat. to 30° S. lat., the temperature of the surface of the sea does not vary during the day quite so much as one degree Fahrenheit. Off the coast of Scotland the daily variation is only 0·3°, and in higher latitudes still less. On the other hand, the daily variation of the upper layer of the surface of the land is frequently 50°, and in many cases very much greater. Hence the enormously different results which large masses of land and sea respectively exercise on climate. The temperature of the air over the ocean is about three times greater than

that of the surface of the open sea over which it lies; but on nearing land it is nearly five times greater. The least daily variation on land is in insular situations, being at Rothesay about 5° ; and the greatest in the Sahara regions of tropical and subtropical countries, where it is in many places 30° , rising on occasions to 40° and upwards. The daily minimum temperature occurs some time before dawn; and as regards the maximum, it occurs from 1 to 4 P.M., according to season and geographical situation, the earlier hour obtaining in arid climates and at true high-level observatories, and the later in climates characteristically humid.

The *absolute humidity* of the air, or, as it is usually termed, the elastic force of vapour, is seen in its simplest form on the open sea, as disclosed by the *Challenger* observations. The minimum occurs at 4 A.M. and the maximum at 2 P.M., thus approximating closely to the diurnal march of the temperature; and on nearing land a secondary minimum prevails from 10 A.M. to 4 P.M., due doubtless to the drier descending aerial currents which take the place of the currents that ascend from the heated surfaces of the land. The *relative humidity* is widely different from the vapour pressure, and presents features of the simplest character. The maximum occurs from midnight to 4 A.M.; or when the temperature is lowest the air is nearest to saturation. On the other hand, the minimum is about 2 P.M.; or when temperature is highest the air is furthest from saturation. This feature of the humidity characterises all climates. When the air is by terrestrial radiation cooled below the dew-point dew is deposited, and when the temperature is below 32° hoar-frost is the result.

The *diurnal oscillations of the barometer* show two maxima and minima—the maxima occurring about 9 to 10 A.M. and 9 to 10 P.M., and the minima from 3 to 4 A.M. and 3 to 4 P.M. Since the temperature of the surface of the sea does not vary quite one degree during the day, and since these oscillations occur equally over the open sea as on land, it conclusively follows that they are independent of the temperature of the part of the surface of the globe on which the air rests. Generally speaking, the amount of the oscillations decreases with latitude. Taking latitude with latitude, the amounts are greatest over land surfaces which are greatly heated during the day and cooled during the night, and least over the anticyclonic regions of the great oceans lying to the westward of the continents from about 20° to 40° N. and S. lat. The characteristics of these anticyclonic regions is a vast descending current down their central spaces. This air necessarily increases in temperature with its descent, and consequently is further removed from saturation; and it is probably due to this circumstance that the amount of the barometric oscillation is here reduced to the minimum for the latitude over all anticyclonic regions.

It has been further shown from the *Challenger* observations that the force of the winds on the open sea is subject to no distinct and uniform diurnal variation, but that on nearing land the force of the wind gives a curve as pronouncedly marked as the ordinary curve of temperature; the minimum occurring from 2 to 4 A.M. and the maximum from noon to 4 P.M. Each of the five great oceans gives the same result—the differences between the hours of least and greatest force being Southern Ocean, $6\frac{1}{2}$ miles; South Pacific, $4\frac{1}{2}$ miles; South Atlantic, $3\frac{1}{2}$ miles; and North Atlantic and North Pacific, 3 miles. This diurnal peculiarity of the wind's force is even still more pronounced over all tolerably open and extended surfaces of the land. But at true high-level observatories, situated on peaks, the reverse everywhere holds, so that the daily

minimum velocity occurs during the warmest hours of the day, and the maximum at night during the coldest hours.

Thunderstorms have well-marked periods of diurnal variation over land and over the open sea respectively. In climates where rain falls equally at all seasons they are of most frequent occurrence during the hottest portions of the day and of the year, so far as concerns the land surfaces of the globe. Taking Ekaterinburg in the Urals as representing inland climates, observations show that there, during the twelve hours from 9 A.M. to 9 P.M. when temperature is above the daily mean, 717 occurred, but only 139 during the other twelve hours when temperature is under the mean. Thus the great majority occur during the time of the day when the ascensional movement of the air from the heated ground takes place, and attain the absolute maximum when the temperature and this upward movement are also at the maximum. On the other hand, the *Challenger* observations on the open sea show that the maximum occurrence is from 10 P.M. to 8 A.M., 22 having been observed during these ten hours and only 10 during the other fourteen hours of the day. This remarkable result suggests that over the ocean terrestrial radiation is more powerful than solar radiation in causing those vertical disturbances in the equilibrium of the atmosphere which give the thunderstorm.

Atmospheric vapour and ascending currents, and the descending currents which necessarily accompany them, play an important part in the development, course, and termination of thunderstorms. Where the climate is dry and rainless, like that of Jerusalem in summer, thunder is altogether unknown; and where an anticyclone with its descending currents rests over a region, as happens over the centre of the Europeo-Asiatic continent in winter, thunder is equally unknown during that season. The diurnal periods of *hail*, *whirlwinds*, *waterspouts*, *dust-storms*, and *tornados* have their origin in substantially the same atmospheric conditions as the thunderstorm, and occur approximately at the same hours of the day.

Meteors are small bodies travelling in vast numbers, and in various directions, through space. Our earth continually encounters them in its orbital path, and they are then revealed to our observation as *aërolites*, *fireballs*, and *shooting or falling stars*. Every night, if the sky be clear, some may be observed, on the average five to seven every hour, while on certain occasions they are so numerous as to present the spectacle of a perfect rain of fire. Besides those visible to the eye, there are numbers unseen, some of which are occasionally noted in the course of telescopic observation. The total number encountered by the earth in one day has been estimated by Professor Newton, of Yale University, United States, at 7,500,000. Their total mass, however, he estimates at only 100 tons, so that individually they must in

general be exceedingly minute. They dissipate, however, a quantity of dust in the upper regions of the air, which in its slow descent and fall upon the earth is easily detected by proper means. Our air in this case acts as a shield, so that, instead of frequent showers of stones descending with deadly force, we have this quiet falling of impalpable dust. Our conclusions regarding meteors are reached by a proper interpretation of various phenomena, long considered as having no mutual connection, but now grouped coherently under one simple explanation. In order to appreciate the reasoning which has led to this result, it will be convenient to consider first the observed facts regarding (1) *aërolites*, (2) fireballs, and (3) shooting-stars.

The first group, *aërolites*, includes all stony or metallic masses actually falling to the earth from the sky. They have been classed as (1) *aërosiderites*, or *siderites*, chiefly consisting of meteoric iron; (2) *aërosiderolites*, or *siderolites*, conglomerates of stone and iron; (3) *aërolites*, almost entirely consisting of stone. The common title *aërolites* embraces, however, all kinds. The descent of such bodies, though rare, has occurred with greater frequency than would be imagined. The British Museum alone has specimens of more than three hundred, of which nearly two hundred were seen to fall. Some sacred stones, as the black stone worshipped at Emesa in Syria, the holy Kaaba of Mecca, and the great stone of the pyramid of Cholula in Mexico, owed their sanctity to a report, probably true, that they had fallen from heaven. It has been suggested that the earliest image of Diana of the Ephesians, which 'fell down from Jupiter,' had taken the place of an actual meteorite. Livy mentions the falling of a shower of stones on the Alban Mount near Rome, about 654 B.C. A Chinese catalogue records the fall of an *aërolite* on January 14, 616 B.C., which broke several chariots and killed ten men. Plutarch and Pliny mention a great stone, as large as a wagon, the latter says, and of a burnt colour, the fall of which, at *Ægospotamos* on the Hellespont about 467 B.C., is recorded in the *Parian Chronicle*. In 1492 A.D., 'on Wednesday, November 7,' a stone weighing 260 lb. was seen to fall near *Ensisheim* in Alsace: part of it is still preserved in the village church there. In 1510 about 1200 stones, one weighing 120 lb., another 60 lb., fell near Padua in Italy. We are told that the Emperor *Jehangir* caused a sword to be forged from a mass of meteoric iron which fell at *Jullunder* in the Punjab in 1620. On November 27, 1627, the astronomer *Gassendi* witnessed the fall of a stone weighing 59 lb. at *Mount Vasier* in Provence. At *Wold Cottage*, Yorkshire, December 13, 1795, a ploughman saw a stone of 56 lb. weight fall near him in a field. But the most interesting of such modern observations was made on April 26, 1803, near *L'Aigle*, in Normandy. About 1 P.M. a brilliant fireball was seen traversing the air at great speed. A violent explosion followed, apparently proceeding from a small and lofty cloud, followed by a shower of thousands of stones, one 8 lb. in weight. A large meteorite exploded with prodigious noise over *Madrid* on 10th February 1896. On April 20, 1876, a mass of meteoric iron more than 7 lb. weight fell at *Rowton* in Shropshire, accompanied also by an explosion. On September 4, 1887, a large *aërolite* fell at *Krasnoslobodsk*, in the government of *Penza*. It was accompanied by a loud explosion, and in it (as in some others) were found crystals having all the chemical properties of the diamond. In nearly every one of these and other cases are noticed the following features—(1) a noise, often an explosion; (2) cloud or smoke; (3) partial fusion of the mass or masses, especially on the surface. These indicate that the *aërolite* by

some means is brought to a very high temperature, at least above the melting-point of iron, which often causes it to burst into fragments. A theory has been advanced that *aërolites* are ejected from active volcanoes, as this would account for their high temperature. This is not borne out by observation, and, moreover, fails to account for their high velocities. The high temperature on the surface is satisfactorily explained by the friction of the earth's atmosphere, provided the velocity is sufficiently great. A sufficient velocity is at once guaranteed when we consider *aërolites* as simply *fireballs* whose mass and course are such as to bring them entirely through our atmosphere into contact with the earth. It has therefore been concluded that fireballs are bodies which have their origin outside the earth, and have fallen upon it. Meteoric iron is also alloyed with nickel, cobalt, manganese, magnesium, copper, carbon, and tin, in a manner in which it is not yet found alloyed in terrestrial minerals; and this also points to its cosmical origin. Altogether twenty-four of the terrestrial chemical elements have been found in *aërolites*—viz. oxygen, hydrogen, chlorine, sulphur, phosphorus, carbon, silicon, iron, nickel, cobalt, magnesium, chromium, manganese, copper, tin, antimony, aluminium, calcium, potassium, sodium, lithium, titanium, arsenic, and vanadium. No new element not found on earth has been found in them.

The second class of meteors form *fireballs*, which appear as brilliantly luminous bodies, traversing the sky, often with noise, and always with great velocity. *Aërolites* before their fall have often been seen as fireballs, and the substantial unity of the two classes is now universally accepted. Fireballs, then, are regarded as *aërolites* whose mass and course are such that they escape actual contact with the earth. They are much more numerous than *aërolites*, and are of great variety in velocity, size, and brilliance. On August 18, 1783, one of great size traversed the air over Europe, from *Shetland* to *Rome*, at a height of 50 miles and with a speed of 30 miles per second, giving off a greater light than the full moon. More recently, on November 17, 1887, a splendid specimen, seen first over the *Irish Sea*, crossed westwards over *Ireland*, at a height of probably about 20 miles, and disappeared above the *Atlantic*. Many hundreds of such, though usually less brilliant, have been observed. *Arago* enumerates 813. More are constantly being seen. Their height is obtained by comparison of observations at stations widely separated, and from it and their observed speed the actual velocity is computed. From a careful comparison of many observations made by a committee of the *British Association* it appears that in general they appear at a height of between 20 and 130 miles, and have a velocity of between 17 and 80 miles per second, with an average of 34·4 miles per second. Their actual size has been enormously overestimated, at 12,000 to 100 feet in diameter. The effects of irradiation and the luminous gases discharged during their course no doubt give them an apparent diameter enormously greater than the real one, which is probably between that of a marble and a pin-head. They generally leave behind them in their track a luminous train or 'tail' which sometimes disappears at once, and at other times persists for some minutes after the fireball itself disappears. These 'tails' are variously coloured, according probably to the different chemical constitution of the 'heads.'

These bodies reach the earth from interplanetary space. Various other suppositions have been made, such as volcanic explosions, condensation in the atmosphere, and ejection from the moon, but no

observational evidence in favour of any of these suppositions has been adduced. The high average velocities of fireballs, 35 miles per second, compared with the velocity of the earth in its orbit, 18 miles per second, and with planetary and cometary velocities in general, requires for its explanation an extra-terrestrial origin for these bodies. Further, fireballs, by insensible graduations, merge into shooting-stars, and there is ample evidence that there are small bodies circulating like planets round the sun, which have become luminous after entering the earth's atmosphere.

We are thus led to the consideration of *shooting-stars*, which are the most numerous class of meteors. By a peculiarity in their movements, rendered evident by their numbers, a satisfactory explanation of the nature of all classes of meteors has been reached. On any fine night a watcher who is careful and patient for a sufficient time will see a few shooting-stars. Sometimes they are very numerous, and all appear to originate in one part of the sky. From their point of origin they appear to radiate, and if it be overhead and the meteors very numerous the appearance is like an 'umbrella of fire' above the earth. But this point may not

therefore, be passing through a crowd of small bodies, themselves in motion, meeting or passing it on a *definite track*. We have then to ask, what is the form of the meteor track, whence come and whither go the meteors we encounter in such numbers? Usually there is a tolerably definite time, recurring annually, during which a radiant is active. This was the first broad fact impressed upon observers. Although at such yearly periods the number of meteors may be very large or very small, there are at least a *few* almost always seen. From this it was early seen that certain parts of space, through which the earth passed every year, were occupied at the date of such passage by meteors travelling past with planetary velocities.

This leads to the conclusion, drawn by Professor Olmsted of Yale in 1834, that the *Leonid* meteors are bodies revolving about the sun, in an ellipse which meets the earth's elliptic orbit at the point where the earth is on November 14. The meteors are gathered into a cloud or swarm at one particular part of the orbit, but a number of them are scattered along the whole extent of the track. Sometimes, as in 1833, the great swarm is near the point of intersection with the earth's orbit on

November 14, and a grand display is seen. In most years, however, only stragglers along the meteor track are encountered, and a comparatively small number of shooting-stars are to be observed.

In 1864 Professor H. A. Newton of Yale made a careful examination of historical records of showers of *Leonid* meteors. He found records of brilliant displays of meteors in November,

Orbit of the Leonid Meteors.

be overhead. It may even be below the horizon. In the latter case the meteors appear to come up over the horizon like rockets, and ascend into the sky. This *radiant*, as it is technically called, remains fixed among the stars, so that, if at the beginning of an observation it be overhead, it will be perhaps below the horizon by the end of the night's watch. It is either named after the *constellation* in which it is placed, or indicated by its right ascension and declination. For several nights in succession stars may be seen to radiate from nearly the same point of the heavens. *Leonids*—i.e. the meteors whose radiant is in *Leo*—or the famous November meteors, are bright and swift, leaving very durable tracks of light. The *Taurids* (from the constellation Taurus) give many fireballs, and other radiants give meteors of special characteristics, so that each radiant is evidently the source of a family of meteors.

Such a radiating motion is explained by supposing all the meteors to be actually moving in tracks parallel to the line joining the radiant point to the eye of the observer. For, being wholly unconscious of the distance of the meteors, the observer only sees the projection of their paths on the sphere which the eye naturally assumes as the background of all the celestial appearances.

On the occasion of a meteoric shower the earth,

which he identified with the Leonids, on twelve occasions between 902 A.D. and 1833. These were separated by intervals of 33 years or multiples of that number, or more exactly 33.25 years—i.e. three intervals of 33 years and one of 34 in every 133 years. He was so fully convinced of this periodicity that he predicted a grand display on November 13-14, 1866, and the event proved him right.

Prof. Newton then endeavoured to find the period of revolution of the meteors themselves round the sun; 180 days, 185.4, 354.6, 376.6 days, and 33.25 years were found to be possible solutions. Any of these periods is consistent with an ordinary display each November, and a specially fine one at intervals of 33 years. Newton's researches showed that the day of the month on which the great displays of meteors had been seen was becoming later at the rate of one day every 70 years—it was on October 12 (old style) in 902 A.D. and November 13 in 1866. This showed that the point at which the orbit of the meteors intersected that of the earth was slowly changing. Such a change would be brought about by the attractions of the planets on the swarm of meteors, and Adams of Cambridge found, by mathematical calculations, that a change of this exact amount would occur if the period were $33\frac{1}{4}$ years, but not more than $\frac{1}{4}$ ths of the amount with any of

the shorter periods. Knowing the period, Adams easily calculated that the meteors move in a long ellipse, whose nearest point to the sun is just inside that of the earth's orbit, and greatest distance 19.7 times the earth's distance from the sun, or farther than Uranus. The orbit is inclined at an angle of $16^{\circ} 46'$ to the ecliptic—i.e. earth's orbit. No brilliant display occurred in 1899. The explanation given by Stoney and Downing is that the attraction of the planets has diverted the path of the meteors, so that instead of intersecting the earth's orbit it now cuts the ecliptic at a point one million miles nearer the sun.

The study of meteors was also taken up by Schiaparelli in 1866. He assumed that the orbits of the meteors must be long ellipses, and computed a parabolic orbit as a preliminary step for the Perseid meteors which occur August 9-11. His orbit agreed closely with that of Tuttle's comet (1863 iii.). The orbit of the November meteors (Leonids) agrees with Temple's comet (1866 i.): of the Lyrids (April 20) with the first comet of 1861; and the Andromedid meteors (November 28) with Biela's comet. (See COMETS.) Thus a close connection is established between comets and meteors. The head of a comet is regarded as a cluster of meteorites. In the continual passage of the comet round the sun the cluster is gradually spread out over the orbit by the action of gravity. The Perseids (August 9-11) appear to be distributed with some uniformity in their orbit, while the Leonids are clustered in a swarm. Thus the Leonid swarm has been subjected to the disintegrating effect of the sun and planets a shorter time than the Perseids. Leverrier found that in 126 A.D. the path of the Leonid meteors passed very close to the planet Uranus, and suggested that the swarm might have been 'captured' by Uranus. Professor Sampson has shown (*Monthly Notices of the Royal Astronomical Society*, 1914), that in 885 and 1053 the swarm passed equally near to Uranus. As the meteors had been seen before 1053, it is clear that they cannot have been 'captured' in that year. There is no observational evidence earlier than 885, and the 'capture' to the present more restricted orbit may have occurred in that year. This is, however, by no means certain.

The existence of meteorites moving in space has been utilised by Sir N. Lockyer to frame a 'meteoritic' hypothesis in preference to the 'nebular' hypothesis of Laplace. For this reference should be made to his book, *The Meteoritic Hypothesis* (1890).

Some hundreds of 'radiants' are now known, of which the following are the most active: (1) the *Lyrids*, April 19-20; (2) the *Pegasids*, August 10; (3) the *Perseids*, August 9-11; (4) the *Aurigids*, September and October; (5) the *Orionids*, October and November; (6) the *Taurids*, November 1-15; (7) the *Leonids*, November 13-14.

See the manuals cited at ASTRONOMY; Bonney's *Story of our Planet* (1893); the British Association Report on Meteors; Fletcher's *British Museum Handbook*; and Tassin's *U.S. Museum Collection of Meteorites* (1902).

Methodism. Wesley says: 'The first rise of Methodism (so called) was in November 1729, when four of us met together at Oxford. The second was at Savannah in April 1736, when twenty or thirty persons met at my house; the last was at London on this day (May 1, 1738), when forty or fifty of us agreed to meet together every Wednesday evening, in order to a free conversation, begun and ended with singing and prayer' (*Eccles. Hist.* iv. 175).

METHODISM IN OXFORD.—About May 1729 a gentleman of Christ Church, who watched the regular

attendance of Charles Wesley and a student who lived next door to him at the weekly communion, gave them the name of Methodists 'for the regularity of their lives, as well as studies.' Wesley says the name was 'fixed upon them by way of reproach, without their approbation or consent.' He was himself in Lincolnshire at the time serving as his father's curate, but before he left Oxford he had spoken to Charles about personal religion, and at the beginning of 1729 Charles wrote to consult him about keeping a diary, adding: 'It is through your means, I firmly believe, that God will establish what He hath begun in me.' Wesley came to Oxford in June for two months, when the two brothers, with William Morgan and Robert Kirkham, met together almost every evening. Wesley came into residence at Lincoln College in November 1729, and became the leader of the Holy Club which met every evening for prayer and study. In August 1730 the friends began to visit the prisoners at the Castle, and then busied themselves in caring for the sick and promoting the education and religious training of the children of the poor. Oxford thus gave Methodism a name, and taught a band of young scholars to combine personal piety with good works. It was a delightful blend of scholarship, devotion, and charity. Wesley had already learnt that religion meant Christian fellowship; or, as a wise counsellor put it, 'The Bible knows nothing of solitary religion.' Oxford Methodism has been set in a new light by the standard edition of Wesley's *Journal* (1909-15).

METHODISM IN SAVANNAH.—The mission to Georgia transferred the headquarters of Methodism to Savannah, where Wesley laboured with apostolic zeal from February 1736 to December 1737. He wished to work among the Indians, but that door was closed. Wesley therefore gave himself wholly to his parish. 'Every Sunday and holiday' he administered the Lord's Supper. On weekdays he read prayers, and expounded the second lesson at five in the morning and seven in the evening. He formed a little society of the serious part of the congregation, who met 'once or twice a week, in order to instruct, exhort, and reprove one another. And out of these I selected a smaller number, for a more intimate union with each other; in order to which I met them together at my house every Sunday in the forenoon.' Wesley's High Church practices were unpopular, and his exercise of discipline in the case of Mrs Williamson led to his abrupt return to England. Charles Wesley had returned in 1736 after six months of privation and danger. Wesley's labours at Savannah might be regarded as the first attempt to introduce Methodism into parish life. It had left its university moorings, and was at work among the people. Wesley did great good here, but he himself had still much to learn about the way of faith. Intercourse with the Moravians had opened his eyes to the deeper meaning of religion, and on his return to London light came which transformed himself and his message.

METHODISM IN ENGLAND.—Wesley's date for the 'last' rise of Methodism is 1st May 1738. It was not till the 24th of the month that he found rest in Christ, but Peter Böhler, a Moravian just ordained by Zinzendorf for work in Carolina, had already shown him the nature and fruits of faith. The Wesleys preached in all churches that were open to them in London, and addressed meetings of the Religious Societies. After the introduction of field-preaching in April 1739 converts multiplied. Towards the end of that year eight or ten persons in London asked Wesley to spend some time with them in prayer and spiritual counsel. Next day two or three more made the same request. Wesley had just taken a lease of the Foundery in Upper Moorfields, and there he met this society on Thursdays. This date is considered

to mark the beginning of Methodism, and its centenary was kept in 1839. Wesley was already uneasy about some developments at Fetter Lane, and in July 1740 he separated from the society there. About fifty women and twenty-five men left with him and joined his society at the Foundery.

The Society and the Class Meeting.—Similar societies had been formed in Bristol, and met at Wesley's Room in the Horse Fair. A debt on this building led Captain Foy to suggest that every member should contribute a penny per week. It was urged that some could not afford this; but the captain replied, 'Then put eleven of the poorest with me; and if they can give anything, well, I will call on them weekly; and if they can give nothing, I will give for them as well as myself. And each of you call on eleven of your neighbours weekly; receive what they give, and make up what is wanting.' These visitors were called leaders. They had sometimes to report that a member was not living a Christian life. Wesley saw at once that here was the very provision he had long needed for the oversight of the societies. He at once instructed the leaders to make special inquiry into the character of their members, and thus Methodism was provided with a set of lay pastors. At first they visited the members in their own homes; then all met together. 'Advice or reproof was given as need required, quarrels made up, misunderstandings removed; and after an hour or two spent in this labour of love, they concluded with prayer and thanksgiving.' In this way Methodism gained its organisation and its financial basis. The quarterly visitation of the classes began in London in 1742, when a society ticket was prepared with a verse of Scripture upon it. Improper persons could thus be kept out of the meetings. Rules were drawn up for the society by Wesley in 1743. They state: 'There is only one condition previously required in those who desire admission into these societies—viz. a desire to flee from the wrath to come, to be saved from their sins. But wherever this is really fixed in the soul it will be shown by its fruits. It is therefore expected of all who continue therein that they should continue to evidence their desire of salvation, first, by doing no harm, by avoiding evil in every kind; secondly, by doing good, by being in every kind merciful after their power; as they have opportunity, doing good of every possible sort, and, as far as possible, to all men; thirdly, by attending upon all the ordinances of God.'

Polity.—Wesley appointed stewards to look after the weekly and quarterly contributions made in the classes, spending what was necessary in repairs, &c., and sending relief to the poor. It is now the custom for each society to have two stewards who receive contributions from the classes and collections, and pay them over to the proper funds. The poor-stewards prepare for the sacraments and take charge of the contributions for the poor. The leaders' meeting now consists of these stewards, with all class-leaders, one assistant class-leader for any class, junior-society class-leaders who have reached the age of twenty-one, representatives (one for every fifty members up to 400) chosen by the members, any circuit stewards who are members of that society, the chief Sunday school superintendent, if a church member of that society, any Wesley deaconess working there, and the circuit ministers. This meeting has oversight of the society, with disciplinary functions. A circuit is made up of one or more local societies in town and village. Its quarterly meeting invites ministers, manages circuit finance, approves all candidates for the ministry sent forward to the synods, and considers all schemes for building and extension within the circuit. The June meeting has a right to send memo-

rials to Conference. The preacher whose name stands first in the appointment for any circuit is the superintendent, and is responsible for the conduct of affairs. After the death of Wesley the circuits were grouped into districts for closer supervision. The term district synod was adopted in 1892. All the ministers of a district are members. The synods meet in May, and on Wednesday circuit stewards and representatives of the circuits meet with the ministers for the transaction of business. Questions of ministerial character, the examination of candidates for the ministry, &c. are dealt with by the ministers. There is also a September financial synod, composed of ministers and lay members. The synods report to Conference, which is the supreme legislative and disciplinary body. Wesley held his first Conference in 1744. His Deed Poll, executed in 1784, named 100 preachers who were to become the legal Conference after his death. They were to meet once a year, fill up vacancies in their number, appoint a president and secretary, station the preachers, admit proper persons into the ministry, and take general oversight of the societies. The itinerancy of the preachers was secured by a provision that no one must be appointed to any chapel for more than three years except an ordained minister of the Church of England. This is still the law, but means have been found for the extension of the term in special cases. The Conference of 1791 decided that every privilege of the deed of declaration should be shared by all the preachers in full connexion. In 1878 laymen were admitted to the Conference. The Representative Session, consisting of 300 ministers and 300 laymen, now meets first; then the Pastoral Session, for which are reserved questions of ministerial character, appointments to circuits, acceptance of candidates for the ministry, and cases of appeal. The chapels are settled on a model deed. The trustees appoint two chapel stewards to manage the property.

Doctrine.—The deed on which Methodist chapels are settled fixed Wesley's first four volumes of sermons (Nos. 1-44) and his Notes on the New Testament as the doctrinal standards for the preachers. There is no doctrinal test for members or officers. Wesley says: 'Methodism, so called, is the old religion, the religion of the Bible, the religion of the Primitive Church, the religion of the Church of England.' Wesley taught that salvation was free for every man. On this universality of redemption he parted company with Whitefield, who adopted Calvinistic views, in 1739. Wesley held that all who believed in Christ might enjoy the knowledge of their acceptance. He described the witness of the Spirit as 'an inward impression on the soul, whereby the Spirit of God directly witnesses to my spirit that I am a child of God.' Entire sanctification was set forth as the privilege and duty of every believer. Christians were not free from ignorance, mistake, infirmity, or temptation, though they might be free from outward sin, evil thoughts, and evil tempers. Christian perfection he described as 'the humble, gentle, patient love of God and our neighbour, ruling our tempers, words, and actions.'

Services.—In some of Wesley's chief chapels the morning prayers of the Church of England were read by himself or a clergyman who assisted him; in others extempore prayer was used. In 1784 Wesley prepared a revised *Sunday Service* for the use of the Methodists in the United States, and this was also used in England. In 1881 *The Book of Public Prayers and Services* was issued. Some churches adopt this revised liturgy; others have hymns, chants, extempore prayer. Revised forms of the baptismal, sacramental, and marriage services of the Church of England are used. There is a special

service for the public recognition of new members; and on the first Sunday of the New Year a form of covenant first adopted in 1755, modified in 1897, and reshaped in 1924, is used. The Watch-night on the last night of the year is an old Methodist institution which dates back to 1740. The Love-feast which Wesley had kept with his Moravian friends in Georgia was introduced as the representative of the age of the Primitive Church.

History.—For four years after his evangelical conversion Wesley's labours were confined chiefly to London and Bristol. During this time his societies were divided into classes under the care of leaders; and the earliest of the noble band of lay preachers were enlisted, without whose help Methodism must have been limited to a few centres. In 1742 Wesley found his way to the West Riding of Yorkshire and to Newcastle-on-Tyne, where Methodism took deep root. The next year Charles Wesley introduced it to Cornwall, which soon became one of its chief strongholds. Methodism now spread rapidly over all parts of England. In 1747 Wesley paid the first of his forty-two visits to Ireland, to which he gave about six years of his life; in 1751 he went to Scotland, which he visited twenty-two times. Pierce struggles with the mob marked these years of progress. Wesley showed rare courage and tact in these encounters, and won many a notable victory over opposers. By about 1756 the mob had been tamed and Wesley's work firmly rooted. Charles Wesley was married, and confined his labours chiefly to Bristol and London. From 1756 to 1784 may be described as the period of consolidation. City Road Chapel, London, was opened in 1778; the deed of declaration was executed in 1784. Wesley took every precaution for the continuance of his work. When he died in 1791 there were 71,668 members in Great Britain and Ireland, with 294 preachers; in the United States there were 43,265 members and 198 preachers; the mission stations had 5300 members, under the care of 19 missionaries.

After Wesley's death the relation of his societies to the Church of England and the provision for the administration of the sacraments caused much anxious debate. In 1795 the plan of pacification was adopted. The celebration of the Lord's Supper, baptism, burial of the dead by the preachers, and service in church hours were not to be permitted unless a majority of the trustees, stewards, and leaders of that place desired it, and assured the Conference that no separation was likely to result. Where the Lord's Supper had already been peaceably administered it was to be continued. Methodism now grew rapidly. In 1834 a theological college was opened at Hoxton. Wesleyan Methodism now has five ministerial colleges; Didsbury (opened 1842), Richmond, Surrey (1843), Headingley (1868), Handsworth (1881), Wesley House, Cambridge (1921). Cliff College for training lay preachers was opened in 1904. £5000 was set apart from the Centenary Fund for Methodist day-schools, and a great work was done. Many of the schools are now transferred to local authorities. Training colleges for day-school teachers are Westminster, for men, opened in 1851, and Battersea, for women, in 1872. The National Children's Home was founded by Dr Stephenson in 1869. The Wesley Deaconess Institute at Ilkley was opened in 1902. Kingswood School for ministers' sons was founded by Wesley, and Trinity Hall, Southport, is for ministers' daughters. Excellent secondary schools for boys and girls are provided. The Leys School, Cambridge, for boys, was opened, with Dr W. F. Moulton as headmaster, in 1874; Farrington's, Chislehurst, for girls, in 1911. The Centenary Fund (1839) reached £221,939; the Missionary Jubilee (1863-68), £179,000; the Thanksgiving Fund (1878), £297,500; the Twen-

tieth Century Fund (1900), with which the name of Sir Robert W. Perks, Bart., will always be associated, £1,073,782. The Central Hall at Westminster, erected in connexion with this fund, was opened in 1912. Wesley had a Book-room at the Foundery in 1739, of which the Methodist Publishing House is the successor. The Primitive Methodists and United Methodist Church have also prosperous Book-rooms. Wesley taught Methodism to use the press, and began the *Arminian* (Methodist) *Magazine* in 1778, which still appears every month. Besides books, tracts, magazines, the *London Quarterly Review*, the *Holborn Review*, and four important newspapers are issued by English Methodists.

The first secession in Methodism was led by Alexander Kilham, one of the preachers who was expelled in 1796. He wanted to secure a more liberal constitution with larger rights for the laity. Three other preachers joined him, and formed the New Connexion in 1797. In 1827 the introduction of an organ into Brunswick Chapel, Leeds, led to the secession of the Protestant Methodists, who united with the Wesleyan Methodist Association. This sprang out of Dr Warren's agitation in 1836, and was connected with the foundation of the Theological Institution for the training of ministers. A more serious agitation in 1850-52 robbed Wesleyan Methodism of 100,000 members. Those who then separated amalgamated in 1857 with the reformers of 1827 and 1836, forming the Methodist Free Churches. The Bible Christian Connexion owed its origin in 1816 to William O'Bryan, a Cornish local preacher, but was not a secession from Methodism. In 1907 the New Connexion, the Bible Christians, and the Methodist Free Churches formed themselves into the United Methodist Church. The uniting Conference was held in Wesley's Chapel, London. The Conference is composed of equal numbers of ministers and laymen. The ministerial term is four years, subject to annual appointment. It can be extended to seven years if two-thirds of the circuit meeting wish; still further extension may be granted by a special vote of Conference. The Primitive Methodist Church owes its origin to Hugh Bourne and William Clowes, who held camp-meetings on the American plan in the Potteries. The Conference was afraid of this movement, and Hugh Bourne's name was removed from the local preachers' plan and the class-book. The little society formed in 1810 has now grown into a great church, which has exerted a powerful influence over the working-classes. It has a very successful college for the training of ministers in Manchester, and raised more than £300,000 as a Centenary Fund for the extension and consolidation of its work. The Conference is composed of about 68 ministerial and 136 lay representatives. The Welsh Calvinistic Methodists were the fruit of the labours of Whitefield and Howel Harris. In 1910 they formed the Presbyterian Church of Wales, with 190,000 communicants.

Methodism found its widest sphere in the New World. Immigrants from Ireland introduced it into New York and Maryland in 1766. Wesley sent out two preachers in 1769, and two years later Francis Asbury found his way there to become a true apostle. After the War of Independence, Wesley set apart in 1784 Dr Coke as superintendent for America, and instructed him to ordain Asbury as his colleague. They were to ordain certain of the preachers to administer the sacraments. Asbury lived till 1816. He rode 270,000 miles, preached 16,500 sermons, ordained more than 4000 preachers. Methodism advanced by leaps and bounds. The first General Conference of this Methodist Episcopal Church was held in 1790; and in 1808 it was

made a delegated body with power to legislate for the whole church, subject to certain restrictions. In 1830 the Methodist Protestant Church was formed. It had no bishops, and laymen took part in all legislation. In 1844 the General Conference of the Methodist Episcopal Church passed a resolution virtually setting aside one of the bishops who held slaves through marriage, &c. This led to the formation of the Methodist Episcopal Church (South) in 1845, with about 400,000 members. These are the two most powerful churches of the United States. They have flourishing book concerns at New York, Cincinnati, Chicago, and Nashville. Two important reviews, many magazines and newspapers, are issued. The educational work is very extensive, and large European and foreign missions are carried on. Canadian Methodism is growing stronger every year. It has a prosperous book concern in Toronto. All branches of Methodism were united into the Canadian Methodist Church in 1883. A broader union with Presbyterians and Congregationalists was effected in 1925. Its title is The United Church of Canada. Large schemes for reunion are under discussion both in the United States and in Great Britain. The Methodist Churches in Australasia were united in 1902. The number of Methodist members and adherents is estimated at 35,000,000.

See, besides the Works and the Lives of the Wesleys and of Whitefield, George Smith's *History of Methodism* (1862); Abel Stevens's *History of the Religious Movement called Methodism* (New York, 1861); Daniel's *Short History of the Methodists* (1882). A *New History of Methodism*, edited by W. J. Townsend, H. B. Workman, and G. Eays; A *History of Methodism*, by J. R. Gregory; *Annotated Popular History of Methodism*, by John Telford; *Methodism* (1912), by H. B. Workman; *John Wesley and the Religious Societies* (1921), *John Wesley and the Methodist Societies* (1923), *John Wesley and the Advance of Methodism* (1925), by Dr Simon; *Proceedings of the Wesley Historical Society*; and works on the polity, constitution, and economy of Methodism by Peirce, Rigg, Waller, and Simon. For Methodist missions, see MISSIONS. For general statistics, see *Minutes of Wesleyan Methodist Conference*.

Methodius. See CYRIL.—Another METHIDIUS, bishop of Olympus in Lycia, and perhaps afterwards of Tyre, wrote the *Banquet* and other dialogues, and was martyred about 311.

Methuen Treaty, a commercial treaty negotiated in 1703 by Paul Methuen, the English ambassador in Portugal, with that country, to admit Portuguese wines to England at a duty one-third less than that on French wines, the Portuguese undertaking in return to admit English wool, imposing on it, however, the old duty of 23 per cent. *ad valorem*. It was annulled in 1835.

Methyl is an organic radical homologous with Ethyl (q.v.). Its formula is CH_3 , but, as it cannot exist in the free state, two such groups of atoms unite together to form ethane, $\text{CH}_3\text{—CH}_3$. As in the case of ethyl, methyl is the centre of a whole group of substances known as the methyl-group. Thus, the hydride of methyl, CH_3H , known as light carburetted hydrogen, marsh-gas, or fire-damp, is well known as the cause of explosions in coal-mines. It is a light, inodorous gas, half as heavy as air; non-poisonous and very inflammable, forming an explosive mixture with seven volumes of air. Methyl alcohol, CH_3OH , is obtained as a by-product in the manufacture of beet-root sugar, and also by the dry distillation of wood. It is a colourless, mobile liquid, resembling ordinary alcohol in many of its properties. Methyl oxide or methyl ether, $(\text{CH}_3)_2\text{O}$, corresponding to ethyl ether or common ether, is a gas at ordinary temperatures, very soluble in water and alcohol, and capable of being condensed to a liquid by pressure and cold.

It is largely prepared for use in freezing-machines, owing to the intense cold which results when the liquefied gas is allowed to evaporate. It is prepared by the action of sulphuric acid on wood spirit.

Besides the above, methyl enters into the constitution of many ethereal salts and amines, such as methyl chloride, acetate, and salicylate, as well as methyl amine, dimethyl amine, &c. (see AMINES). The salicylate, $\text{CH}_3\text{C}_7\text{H}_5\text{O}_3$, is interesting as being the ethereal oil of *Gaultheria procumbens*, from which pure methyl alcohol and pure salicylic acid can both be made. For Methyl Violet, see DYEING; and for Methylene, see ANÆSTHESIA. —**METHYLATED SPIRIT.** There are two kinds of methylated spirit allowed by the excise. The one sold to the general public consists of 97·5 alcohol, wood-naphtha 2, mineral naphtha 0·5, and a small quantity of pyridine and methyl violet dye. Another form known as 'industrial' is allowed to be used by manufacturers under licence only, and contains no mineral naphtha or methyl violet.

Metonic Cycle. See CHRONOLOGY, GOLDEN NUMBER.

Metope. See ENTABLATURE.

Metre is that kind of rhythm in language which seems to fall into the regular repetition of a pattern or sequence of patterns.

The distinction between poetry and prose is commonly assumed to be equivalent to the distinction between metrical and non-metrical rhythm. The theoretical difficulties and practical inconveniences of this assumption have, since Aristotle noticed them, often been pointed out. There is a good deal of prose or non-metrical composition to which the title of poetry cannot reasonably be refused; we need only refer to Plato's *Dialogues*, the Old Testament, Traherne's *Meditations*, or Baudelaire's prose-poems. On the other hand, the mere presence of metrical rhythm is notoriously insufficient to provide the quality of poetry. Yet the fact that poetry and metrical rhythm are, however incorrectly, so commonly taken to imply each other, suggests that there is, at the least, some strong natural connection between them; and this is confirmed when we notice how ludicrously obtrusive metrical rhythm becomes when unsupported by poetic intention or some poetic quality in the language. It is, moreover, well known that primitive or early poetry is almost always metrical; and attempts to account for this as a mnemonic device, or as the unconscious answer to the rhythmic urgencies of respiration or the pulsation of the blood, may be ignored as irrelevant to the real problem, since they fail to explain how it is that the invention of writing (to say nothing of printing), and the development of instinctive utterance into consciously elaborated technique, have left the connection between poetry and metre as strong as it ever was in barbarous times. The real problem is, What is the nature of this persistent association of poetry and metre? Why does the art of poetry not indeed absolutely require, but at least strongly recommend, the use of metrical rhythm? Without attempting to determine here the inner nature of poetry—the quality of intention or impulse necessary to it—it will be safe to say that, whenever we find poetry, we recognise some unusual degree of instant, subtle, and complex expressiveness in the language. We may therefore suppose that metre is used in poetry because it specialises into some unusual degree of expressiveness the rhythmical energy of language. But before discussing the function of metre it will be advisable to consider the general nature and the chief forms of metre.

Nature of Metre.—There is nothing abstruse in the idea that in metre rhythm falls into the regular repetition of patterns; and this idea

The varied position of the sense-pause in the line, as well as the accommodation of variable rhythm to a constant pattern, will be noticed.

Scansion thus exercised, with due regard for both aspects of metre—the constancy of its base and the variation of its actual rhythm—forms a useful instrument for precisely criticising the technique of individual versification, and for discriminating the different species of metre. But rhythm, and consequently metre, is not always established by the same means; and scansion, before it can begin its work, must first of all be clear as to the form of metre which is being investigated. This will depend on the rhythmical structure of the language in which the metre is composed. Rhythm may be established by (a) *Stress*, the force with which syllables are enunciated; (b) *Quantity*, the duration of syllables; and, more doubtfully (c) *Tone*, the pitch at which syllables are enunciated. These may operate singly or in combination. The combined incidence of stress and raised tone on a syllable may be called its *Accent*.

There are three main forms of metre: (1) The *Alliterative* metre of Anglo-Saxon and other Northern languages, in which stress joins with quantity to give the rhythm; the base here consists simply of the *number* (usually two) of stressed syllables on either side of a sense-pause in the line, without any definite disposition of these stressed syllables among the unstressed syllables, but with alliteration (or repetition of initial sounds) binding together in each line the sequence of stressed syllables.

(2) The *Quantitative* metres of Persian, Greek, and Latin, in which quantity independent of stress gives the rhythm; the base here consists of long syllables definitely disposed among short syllables, the variation of speech-rhythm being allowed for by means of a system of arithmetical equivalence between long and short syllables; and the stress, though no doubt powerless to alter the rhythm, yet qualifying it by its changing incidence.

(3) The *Accentual* metres of most modern European languages, in which stress (usually involving also tone) gives the rhythm independent of quantity; the base here consists of accented syllables definitely disposed among unaccented syllables, the speech-rhythm varying this disposition without obliterating its pattern. As a rule, this kind of metre uses rime to bind its lines together in the interests of larger periodic rhythms; though, as in blank verse, it can dispense with rime.

Function of Metre.—All rhythm, and especially the rhythm that assumes the insistent formality of metre, exhibits not merely continuity, but also a power of continually generating larger and more inclusive rhythms; just as the rhythmical elements or feet combine to form the rhythm of the line, so the line-rhythms combine to form inclusive masses of rhythm, whether in prescribed stanzas by means of the structural combinations of rime or in paragraphs without rime. In either case, an important function of metre is to give, or at least, in very long poems, to suggest, that formal unity of impression without which no work of art can effectively exist. Akin to this purely æsthetic effect of metre is its emotional effect. The excitement and exaltation accompanying the conception of a poem, with its sense of an unusual significance in things, must be expressed if the poet is to convey the whole of his experience; and no means of expression of this can compare with the proper iteration of insistent rhythm. Metre, with its apparent repetition of marked rhythmical patterns, can provoke the required general heightening of mental tone so long as it does not neutralise this by the tedium of an artificial limitation of natural speech-rhythm. At the same time, the *momentary* emotional expressiveness of rhythm is measured by its variability;

and in metre the expressive variations of rhythm are strongly enforced and made peculiarly noticeable by the fact that they always take place against an accepted constancy of rhythm. So that, both by its constancy and by its variation, metre is the one form of rhythm capable of satisfying every demand which poetry can make of this aspect of its medium, both for momentary and for total expressiveness.

Metre, the basis of the 'metrical' or modern French system of weights and measures, and the unit of length. The first suggestion of a change on the previous system dates as far back as the time of Philip the Fair; but up till 1790 no important change had been effected. On the 8th May 1790 proposals were made by the French government to the British, for the meeting of an equal number of members from the Academy of Sciences and the Royal Society of London, to determine the length of the simple pendulum vibrating seconds in N. lat. 45° at the level of the sea, with the view of making this the unit of a new system of measures. The British government, however, did not give this proposal a favourable reception, and it fell to the ground. The French government, impatient to effect a reform, obtained the appointment by the Academy of Sciences of a commission composed of Borda, Lagrange, Laplace, Monge, and Condorcet, to choose from the following three, the length of the pendulum, the fourth part of the equator, and the fourth part of the meridian, the one best fitted for their purpose. The commission decided in favour of the last—resolving that the $\frac{1}{4}$ of a quadrant of the Meridian (q.v.) be taken for the basis of the new system, and be called a 'mètre.' Delambre and Mechain were immediately charged with the measurement of the meridian between Dunkerque and Barcelona; and the result of their labours was referred to a committee of twenty members, nine of whom were French, the rest having been deputed by the governments of Holland, Savoy, Denmark, Spain, Tuscany, and the Roman, Cisalpine, Ligurian, and Helvetic republics. By this committee the length of the metre was found to be 443·296 Parisian lines, or 39·3707904 English inches; and standards of it and of the kilogramme (see GRAMME) were constructed, and deposited among the archives of France, where they still remain. It is now known that the earth's quadrant is not 10,000,000, but 10,000,880 standard metres, so that after all the standard metre is an arbitrary unit of length. If we call the metre 3 feet $\frac{3}{8}$ inches our error will be $\frac{1}{160}$ inch only. The 'metrical system' received legal sanction 2d November 1801. The following are the fractions and multiples of the metre:

English Inches.			
Millimetre,	·0833707904		
Centimetre,	·833707904		
Decimetre,	3·93707904	English Feet,	English Yards.
METRE,	39·3707904	=	3·28083992 = 1·093633
Decametre,	393·707904	=	32·808992 = 10·93633
Hectometre,	3937·07904	=	328·08992 = 109·3633
Kilometre,	39370·7904	=	3280·8992 = 1093·633
Myriametre,	393707·904	=	32808·992 = 10936·33

The term 'metric system' is also extended to the French square measure based on the Are (q.v.), which is a square the side of which is ten metres; to the measure of weight based on the Gramme (q.v.), which is the weight of a cubic centimetre of distilled water; to the measure of capacity based on the Litre (q.v.), the volume of a cubic decimetre; and to the cubic measurement based on the Stère (q.v.), which is a cubic metre. The metre is practically $1\frac{1}{8}$ yard. The kilometre is = 0·621 of a mile; the square kilometre (kilomètre carré) is = 0·386 of a square mile. See DECIMAL SYSTEM.

Metronome, a small machine for indicating the correct time or speed at which a musical com-

position should be played. It is essentially an inverted pendulum moved by clockwork. The time is regulated by a weight which can be pushed up and down the pendulum-rod, on which is a graduated scale.

Metropolitan. See ARCHBISHOP.

Metternich, CLEMENS WENZEL NEPOMUK LOTHAR, Prince von Metternich and Duke of Potentilla, an eminent Austrian diplomatist, was born at Coblenz, 15th May 1773. His ancestors had obtained distinction in the wars of the empire against the Turks; his family had supplied more than one elector to the archbishoprics of Mainz and Treves; and his father, Franz Georg Karl, Count von Metternich, had secured a high reputation as a diplomatist and as the associate of Kaunitz. Young Metternich therefore entered the service of his country under the most favourable auspices, of which he was not slow in taking advantage. At the age of fifteen he matriculated at the university of Strasburg, where he had for his fellow-student Benjamin Constant, and from which he removed, two years afterwards, to Mainz to complete his education. In 1794, after a short visit to England, he was attached to the Austrian embassy at the Hague, in the following year marrying the granddaughter and heiress of his father's friend Kaunitz. He first came into notice at the congress of Rastadt, where he represented the Westphalian nobility, after which he accompanied Count Stadion to St Petersburg. From this point his rise was very rapid, as he added to the advantages of his birth and connections a more than ordinary share of diplomatic ability, with the most graceful and winning manners. At twenty-eight he was appointed Austrian minister at the court of Dresden, and after the lapse of two years he was sent as ambassador to Berlin, where he took a leading part in the well-known coalition which was dissolved by the battle of Austerlitz. After the peace of Presburg young Metternich was selected for the most important diplomatic appointment in the gift of the emperor—that of minister at the court of Napoleon. When he presented himself before the emperor, he was greeted with the remark, 'You are very young to represent so powerful a monarchy.' 'Your majesty was not older at Austerlitz,' replied Metternich, with a slight exaggeration which could not make the compliment less acceptable; and, indeed, young as he was, he exhibited an address and a knowledge before which Napoleon might bluster, but of which he never could get the better. Without much ardour, with very limited sympathies, with no deep convictions, he had a clear head and a firm hand; he could keep his own secret, and he could worm out the secrets of others; and, making himself the most agreeable man in the world, he plotted with a smiling countenance, manœuvred in a dance, and struck the hardest when he seemed to yield the most.

In 1807 he concluded the treaty of Fontainebleau, very favourable to the interests of Austria; and on the outbreak of the war between France and Austria in 1809 he was detained some time before he could obtain his passport. In the course of that year he succeeded Count Stadion as minister of Foreign Affairs, and it was during his tenure of office that he conceived the idea of a marriage between Napoleon and an Austrian archduchess as a means of purchasing a respite for the empire. Metternich escorted Marie Louise to Paris. Amidst the difficulties of 1812-13 Metternich maintained at first a temporising policy, but the obstinacy of Napoleon at length led him to resolve upon the declaration of war with France made in August 1813. In the autumn of that year the grand

alliance was signed at Teplitz, and Metternich, in recognition of his great ability in connection with the negotiations, was raised to the dignity of a prince of the empire. In the subsequent conferences and treaties the newly-created prince took a very prominent part, and he subsequently signed on behalf of Austria the second treaty of Paris on 20th November 1815. He afterwards paid a visit to England, and was made an LL.D. by the university of Oxford—the only honour this man of countless orders ever received from Britain. After this he still continued to conduct the diplomacy of Austria; in 1821 he was appointed chancellor of the empire, and in 1826 succeeded Count Zichy as president of ministerial conferences on home affairs. His efforts were now earnestly directed to the maintenance of peace in Europe and the preservation of the existing state of things in the Austrian dominions by the strictest measures of police and severe despotism. In the mildest expressions of individual opinion he saw symptoms of dangerous agitation, and his supreme object was to combine what he called the conservative forces of society against anarchy. Then came the French Revolution of 1848, and Metternich's hatred of revolution was fanatical. The shock, which overturned for a time half the thrones of Europe, was felt at Vienna, and the government fell, in spite of the resistance of Metternich, who maintained his policy of 'thorough' to the last. Leaving Vienna with an escort of cavalry, he fled to England, and there he remained till 1851, in the autumn of which year he made a sort of royal progress to his castle of Johannisberg on the Rhine. From this time, although the advice of the old statesman was occasionally asked by the emperor, he was never again requested to assume office. He died at Vienna on 11th June 1859. The *Autobiography* of Metternich (French, 1879-82; German, 1880-84; Eng. trans. 1880-83), edited by his son, throws valuable light on the stirring times in which he lived. In these volumes also appears the diary of his third wife, Countess Melanie Zichy-Ferraris, whom he married in 1831. She was a clever and beautiful woman, and gave her husband much effective aid. From many entries in her diary it is evident that, if her husband was stern and harsh in political strife, he was not without warm and genial affections. To her Metternich was as good and great a man as ever lived, and she expresses more than once her opinion that he alone 'could save the world.'

See works by Binder (1836), Gross-Hoffinger (1846), Schmidt-Weissenfels (1861), Beer (1877), Colonel Malleon (1888), Demelitsch (vol. i. 1898), Sandeman (1911), Welschinger (1913), and Gentz, and his own memoirs; besides such articles as AUSTRIA, VIENNA, &c.

Mettray, a village of France, 5 miles N. of Tours by rail, noted for its great agricultural and industrial reformatory, the parent of all such institutions (1839). See REFORMATORIES, &c.

Metz, the strongest fortress of Lorraine, stands on the river Moselle at the influx of the Seille, 216 miles E. of Paris. The strength of the place consists in its exterior defences, of which the principal are a cordon of forts, some greatly strengthened and improved since the German annexation, and some entirely new. The cathedral, a Gothic edifice (14th to 16th century), is remarkable for its vast size and its architectural lightness, and has a beautiful spire of open work, 363 feet in height. Of other Catholic churches, the most interesting is St Vincent's. The city has a library, a museum, a military academy, a music school, art and numismatic collections, &c. Apart from tanning and the making of saddles and shoes, there are few industries, though there are several iron-works in the vicinity. The trade is chiefly in

wine, brandy, preserved fruits, leather, &c. Pop., which in 1869 was 48,325, had in 1875, by reason of emigration into France, decreased to 45,856; and by emigration to Germany, &c., fell from 79,318 in 1910 to 62,311 in 1921. The Protestants are less than half as numerous as the Catholics. Metz, known to the Romans as *Divodurum*, was afterwards called Mettis (from *Mediomatrici*, the name of the people), hence the present form. Under the Franks it was the capital of Austrasia, and in 870 passed to the empire; it was afterwards made a free city of the empire. In 1552 it was treacherously taken possession of by the French; and, although Charles V. besieged the place from October 1552 to January 1553, they kept it till it was formally ceded to them in 1648. The fortifications, already strong, were completely reconstructed by Vauban in 1674; they were added to at various dates, and after 1830 thoroughly restored. In August 1870 Bazaine was compelled to retire with his army into Metz, which after a long siege was taken by the Germans; the treaty of Frankfurt annexed it to Germany, that of Versailles to France.

Metzgeria, a genus of Liverworts (q.v.).

Meudon, a village 5 miles W. of Paris by the railway to Versailles. The château, rebuilt by Mansard for the Dauphin in 1695, and fitted up for Marie Louise by Napoleon in 1812, was reduced to ruin during the bombardment of Paris in 1871. The Forest is a favourite holiday resort. There is an observatory. Rabelais was curé of Meudon. Pop. 10,000.

Meulebeké, a town in the Belgian province of West Flanders, on the Mandel, a tributary of the Lys, 24 miles SW. of Ghent; pop. 10,000.

Meulen, ADAM (not ANTOINE) FRANÇOIS VAN DER, Flemish painter, born at Brussels, 11th January 1632 (not 1634), was appointed by Colbert in 1666 battle-painter to Louis XIV., and thenceforward accompanied that king in his military expeditions. A long series of Van der Meulen's battle-pictures hang in the Louvre. He died in Paris, 15th October 1690.

Meung, JEAN DE, or Jean Clopinel, or Chopinel, a French satirist, the Voltaire of the middle ages as Gaston Paris calls him, was born at Meun-sur-Loire about 1250. He flourished under Philip the Fair, translated many books into French, became rich and prosperous, and died before November 1305. His *Testament* in single-rimed quatrains, with all its raillery, reveals a genuine piety. But his great work is his continuation to the length of 22,817 lines of the *Roman de la Rose*, left unfinished in 4670 lines by William of Lorris before 1260. He preserved the original metre, but completely altered the treatment, substituting for its tenderness, refinement, and elaborate allegorising, sharp satirical pictures of actual life, forming an invaluable mirror of the middle ages. See *Hist. Litt. de la France*, vol. xxviii.

Meunier, CONSTANTIN (1831–1905), Belgian painter and sculptor, born at Brussels, by the vigour of his art became a master from whom artists in other countries took inspiration. To him we owe the beautiful groups of the mining and industrial life of his country which he presented with great realism and strength ('*La glorification du travail*').

Meursius, JOHANNES, the elder (properly Jan de Meurs), a learned scholar, was born at Loozuinen near The Hague, 9th February 1579, studied philology at Leyden, next travelled through Europe with the son of the Grand-pensionary Barneveldt, and became in 1610 professor of History, and next year of Greek, at Leyden, and afterwards Historio-

grapher to the States-general. In 1625 he became professor of History in the academy at Sorø in Denmark, and here he died, 20th September 1639. His industry was portentous, and his works are a storehouse of materials for students, especially in Greek antiquities. He edited Cato's *De Re Rustica*, Plato's *Timeus*, the *Characters* of Theophrastus, and a long series of the writings of the later Greek writers, as Lycophron, Constantinus Porphyrogenitus, Philostratus, Aristoxenus, Constantinus Manasses, Theophylact, Theodorus Metochites, Antigonus Carystius, Apollonius Dyskolus, and Phlegon. Other works are the useful *Glossarium Græco-Barbarum* (1614), *Res Belgicæ* (1612), *Athens Batavæ* (1625), *Historia Danica* (1630), and a long series of monographs on questions of Greek antiquities which may be found in the *Thesaurus Antiquitatum Græcarum* of Gronovius. A collected edition of his works was prepared by Lami (12 vols. Flor. 1741–63).—His son, JOHANNES MEURIUS, the younger, was born at Leyden in 1613, and died in Denmark in 1654. He wrote several antiquarian works of value, but his name by a singular misfortune survives in connection with the filthy *Elegantie lingvæ Latine* (best ed. Leyden, 1757), with which it is certain that he had nothing to do. The original edition bears neither place nor date, but was most probably printed about 1680 at Lyon or Grenoble. It contains a little poem by Chorier (1609–92), hence his name has been too easily connected with the book, the origin of which still remains an unsolved puzzle.

Meurthe-et-Moselle, a department in the north-east of France, formed, after the treaty of 1871 with Germany, out of what remained of the former departments of Moselle and Meurthe. It has four arrondissements—Briey, Lunéville, Nancy, and Toul—an area of 2020 sq. m., and a pop. (1872) of 365,137; (1921) 503,810. The capital is Nancy. The department belongs to the plateau of Lorraine, has very fertile soil, producing corn, wine, potatoes, fruit, beet-root for sugar, hops, &c., and is drained by the Moselle and its tributaries. It has valuable iron-mines, and is the first department in France for iron and steel; there are also important manufactures of glass, pottery, woollens, cottons, chemicals, tobacco, paper, beer, artificial flowers, and embroidery-work. Rock-salt is mined in large quantities. In point of popular education it ranks second amongst the French departments, Doubs being first.

Meuse (Dutch *Maas*), an affluent of the Rhine, rises in the French department of Haute-Marne, flows in a northerly direction in a deep, narrow, winding valley, past Verdun and Sedan, entering Belgium just below Givet, on to Namur, whence it makes a huge curve to the east, then flows north past Liège and Maastricht, and, bending abruptly to the west, joins the Waal, one of the mouths of the Rhine, opposite Gorkum. The united streams take the name of the Maas, which soon divides again. The southern branch passes through the Biesbosch and Hollandsche Diep, and, again dividing, reaches the sea in two wide estuaries, Haringvliet and De Krammer. The northern branch, called the Merwede as far as Dordrecht and to the west of that town the Old Maas, likewise reaches the sea in two channels, the Old and the New Maas. On this last stands Rotterdam. The entire river is 500 miles in length; it is navigable from Verdun. Area of basin, 18,530 sq. m. Its principal affluents are the Sambre on the left and the Ourthe on the right.

Meuse, a department in the north-east of France, touching Belgium in the north; area, 2400 sq. m.; pop. (1872) 284,725; (1921) 207,309. The surface is traversed from south-east to north-

west by the wooded Argonne ranges, which form the right and left banks of the river Meuse, and separate it from the basin of the Seine on the west and from that of the Moselle on the east. The soil in the valleys is fertile and well cultivated. Wheat, oats, beet-root (for sugar), hemp, oil-plants, and wine are the principal products. Iron is mined and manufactured; glass and paper are the chief branches of industry. The four *arrondissements* are Bar-le-Duc, Commercy, Montmédy, and Verdun. The capital is Bar-le-Duc.

Mexico, an inland state of the republic of Mexico, on the central plateau, adjoining the federal district. The state is fertile, has silver-mines, and several volcanoes. It does not include the city of Mexico (q.v.), which is in a federal territory. Area, 9000 sq. m.; pop. 880,000; capital, Toluca.

Mexico (*Méjico*), a southerly country of North America, is a federal republic, embracing twenty-eight states, a federal district, and two territories. It extends between the United States and Guatemala, with an extreme length of nearly 2000 miles; its breadth varies between 1000 and (in the Isthmus of Tehuantepec) 130 miles. It has a coast-line of 6000 miles or more, but with scarcely a safe harbour beyond the noble haven of Acapulco; on the Atlantic side, with its sandbanks and lagoons, there are only open roadsteads, or river-mouths closed to ocean vessels by bars and shallows; harbour-works, however, have mitigated these disadvantages at Vera Cruz and Tampico. From the south-eastern and north-western extremities of the republic there extend the peninsulas of Yucatán and Lower California, enclosing the Gulfs of Campeche and California respectively.

The figures in the following table can in most cases be accepted only as approximate: large sections of Michoacán and Guerrero, and also of Sonora, have not yet been explored; and there are still many Indians that have never even come in contact with the white man. Of the entire population the whites are estimated to form 20 per cent., the Indians 35, and the half-castes (*mestizos*) 45.

Surface.—For the most part Mexico consists of an immense tableland, which commences in the United States as far north as Colorado, and gradually rises to over 8100 feet at Marquez, 76 miles N. by W. of Mexico city; and a mean elevation nearly as great is maintained in all the south central plateau: at Ciudad Juárez, on the northern frontier, the elevation is only 3717 feet. The prevailing metamorphic formations are partly overlaid by igneous rocks of every epoch, rich in metalliferous ores. In the highest ranges granites and other igneous rocks prevail, with deposits of sulphur and pumice, and other recent volcanic discharges. In the north chalk and sandstones become prevalent. The escarpments of this plateau form most of the so-called Cordilleras; Humboldt's theory of a continuous chain extending from Patagonia to Alaska has now been abandoned. The most important range is the Sierra Madre (over 10,000 feet, and extending from Tehuantepec into the United States); parallel with this run the sierras of the east coast and of Lower California. The surface of the country is also much broken up by short cross-ridges and detached hills. The highest peaks of Mexico are all volcanic, including Orizaba (Citlaltépetl), 18,250 feet high, Popocatepetl (17,880 feet), Ixtaccihuatl (17,000), and Nevado de Toluca (15,000)—none of them reaching the altitude of Mount McKinley. Most of the Mexican volcanoes are extinct or quiescent, and violent earthquakes are of rare occurrence. No disturbance so remarkable has occurred since the upheaval of Jorullo (q.v.) in 1759. On the Atlantic side the plateau descends abruptly to the narrow strip (about 60 miles) of gently sloping coast-land; towards the Pacific, where the coast-lands vary in width from 40 to 70 miles, the descent is more gradual. Of the present lakes the only one of great size is Chapala (q.v.), which is traversed by the Rio Grande de Santiago; but considerable bodies of water collect in depressions in the uplands during the heavy rains, and even flood the surrounding country for a time. The rivers of Mexico are of little use for navigation. South of the Rio Grande del Norte, on the Texan frontier, they are mostly impetuous mountain-torrents, or flow through rocky gorges (*barrañcas*), sometimes 1000 feet deep. Only in the narrow strips between the plateau and the coast are they available as channels of trade and communication; and in this respect perhaps Arabia alone is less favoured than Mexico.

Climate and Agriculture.—In the plateau region, or *tierras templadas*, the climate is almost that of perpetual spring, and the atmosphere remarkably free from moisture. It is to this peculiar dryness that the city of Mexico, the soil of which has been soaked with the filth of centuries and never properly drained, owes its immunity from pestilence; but, on the other hand, throughout the plateau agriculture is dependent on the use and control of water for irrigation purposes, and an immense desert tract extends between Chihuahua and Zacatecas. Wood in all this upland region is scarce and dear, though there are valuable forests in the extreme north and south. On the coast-lands wood and water are abundant, and the soil fertile, but the climate is such that white men cannot work as labourers there. Yet Mexico contains as fine agricultural land as any in the world, and in most parts two crops a year are grown. Northern Mexico is the original home of the 'cattle-range' business, and there vast herds of horses, cattle, and sheep form the principal wealth of the people. The coast-belt and the terraces up to 3000 feet constitute the *tierras calientes*, where the temperature ranges from 60° to 110° F., and, in the south at least, magnificent tropical vegetation and yellow fever and *vómito* used to reign with

equal vigour. Two or three hours by the Vera Cruz Railway carry the traveller from Esperanza, at the very edge of the plateau, down into the heart of the tropics. The cold lands, or *tierras frias*, embrace all the country above about 8000 feet, including the few highest peaks covered with perpetual snow. South of about 28° N. there are only the wet and the dry season, the former from June to October. Farther north there are four seasons; but in the highest zone the rainfall is very scanty, and northern Mexico and the Californian peninsula especially are exposed to seasons of drought. The vegetation of Mexico has the same wide range as the climate. In the lowlands dye-woods and valuable timbers abound in the virgin forests, as well as henequen, medicinal plants, india-rubber, palms, &c.; and oranges and bananas, many varieties of cactus, olives, sugar, coffee, cocoa, rice, indigo, cotton, and tobacco, besides the omnipresent maize, all thrive. Many of these products, including the palms, oranges, cacti, olives, tobacco, and of course the maize, grow as readily over a great part of the temperate zone, where the characteristic vegetation embraces pines, evergreen oaks, the magney or *Agave americana* (q.v.). The last is nearly as frequent also in the *tierras frias*. The vine flourishes in some districts, especially near Ciudad Juárez, Durango, and Parras in Coahuila, where a good wine is made; and mulberry-plants have been imported from Europe to develop the silk industry. In Lower California a good deal of Archil (q.v.) is collected. Chicle gum is extracted and prepared in the forests along the coast. But agriculture in Mexico is very poorly developed. Primitive methods are followed by the people generally, and the American plough has only in a few localities displaced the crooked stick, sometimes shod with iron, and lashed by raw-hide thongs to the oxen's horns. There is, however, some agricultural machinery in use on the larger *haciendas* or great landed estates. To their absentee owners such estates, in spite of the expense of irrigation and the shiftless methods in use, are said to return large incomes; but the difficulty and cost of transport are so great that in many parts of Mexico no more corn is grown than suffices to meet the wants of the immediate neighbourhood. The staple crop is maize. The other principal crops are wheat, beans, barley, tobacco, cotton, sugar-cane, coffee. Henequen or sisal hemp is exported in large quantities.

Minerals.—Mexico is rich in minerals, many of which have been worked from a very early date. Silver-mining, especially, has been an important industry ever since the conquest, and a considerable number of the mines are still worked in all parts of the country. Gold is also produced. The coinage records, which date from 1537, and may be taken as substantially accurate, show the production of the precious metals from that year and for the next three and a half centuries to have been: gold, 114,000,000 Mexican dollars; silver, 3,000,000,000 Mexican dollars. Copper is largely mined in some sections, being found in a pure state in Chiapas and Guanajuato, and elsewhere associated with gold. Other important minerals are iron, including enormous masses of meteoric iron ore, and the mountain a mile from Durango, the Cerro de Mercado, a solid mass of magnetic iron ore; lead, found associated with silver; and sulphur, zinc, quicksilver, platinum, manganese, antimony, cinnabar, besides salt, graphite, marble, alabaster, gypsum, asphalt, and petroleum in great quantities, and some tungsten, molybdenum, and opals. There are also large deposits of coal, some of excellent quality, in various localities; but as yet little of it has been mined, mostly in the state of Coahuila. Mexico has about a thousand

petroleum wells, distributed over wide areas. The development of the oil-fields has been very rapid. From 3½ million barrels in 1908 the yield has risen to nearly 200 million.

Manufactures and Trade.—The manufacturing industries, which in the past had progressed slowly, developed rapidly under Porfirio Diaz's administration, owing to stable government and the consequent advent of much foreign capital, although as yet the manufactured articles are almost confined to what is required for home consumption. The principal manufacture is a coarse cotton cloth. There are also a good many distilleries and tobacco-factories, and several paper and numerous sugar mills, not to speak of smaller manufactures of candles, glass, porcelain; and the extraction of henequen fibre, too, is an important industry. Bounties are offered by some states for the establishment of factories within their bounds. But the handicraft production of such articles as pottery, saddles, sandals, many coarser textiles, the national hat, the sombrero, and the national drinks, pulque, mescal, and tequila, all from the various plants of the magney family (see AGAVE), is much more considerable. The great bulk of the Mexican exports is always formed by the precious metals—coin, bullion, and ores; yet the amount of agricultural products and other merchandise has greatly increased since the construction of railways. Of these in 1860 there were none; in 1880 there were 655 miles; now about 16,000 miles, open for traffic. The rapid construction of these lines, most of them in English hands, saddled the country with heavy responsibilities. Most of the railways have been taken over by the government since 1914. Many important productive regions, notably the peninsulas, have suffered from want of railway connection with other parts of the republic. This problem is now engaging the attention of the government. The spread of the railways was made an excuse for the almost utter neglect of the roads, which throughout Mexico were bad enough before. The fine highways constructed by the Spaniards were allowed to fall into destruction during the long civil wars, and their present deplorable condition makes them rather a hindrance than a help in the development of the country. A still more serious obstacle to internal commerce has been the crushing system of inter-state customs—the *alcabalas*—a heritage from the days of Spanish rule; they were abolished by a decree of 1886, but some of them continued to exist under other names. Under the excise system, moreover, nearly every possible product, every branch of industry, every social function even, is taxed; and a swarm of petty officials in every city, town, and hamlet see that nothing escapes its tax, from a bag of seaweed or shavings to a funeral or a fandango. Of the exports gold and silver make up about half the total value; petroleum, copper, coffee, henequen, rubber, and hides are also important. Most of the trade is with the United States; Great Britain follows, Germany at some distance, and France yet farther behind. Great Britain imports from Mexico oils, mahogany, log-wood, and silver ore, and exports thither cottons, woollens, and linens, iron, machinery, and coal.

Armed Forces.—The strength of the active army on a peace footing is fixed by law at 50,000 officers and men. Service is compulsory in the active army or the national guard. There is a small navy, and likewise an air-force.

Government Finances, &c.—The Mexican constitution of 1857, and that of 1917 which superseded it, are closely modelled upon that of the United States. The president, who is assisted by seven secretaries of state, is elected by direct popular vote for four years, and can be re-elected for a second term; the senators (two for each state) and

representatives (one for every 60,000 inhabitants) receive a salary of about 7000 dols. a year. Both senators and representatives are elected by universal male suffrage, voters being eighteen years of age if married, twenty-one if unmarried. The several states have elected governors and legislatures. It must be added, however, that neither government nor opposition is conducted on any principle: the government is a personal, and often a tyrannical, one; and the opposition also is personal—it rises and falls with its leader, and in the past has found its favourite and safest expression in revolution, which either lifts the pretender into power or leaves him before a firing-party. Either event dissolves the opposition, for no principle has been involved. A strong government, in these circumstances, is most necessary in Mexico. The judicial system occupies the same position as that of the United States.

Mexico made marvellous progress under the firm rule of President Porfirio Díaz, who so won the confidence of European investors that by their help the country was opened up and industries promoted. Before 1876 Mexico had been in a chronic state of civil war and revolution and contempt for law, a condition of almost complete ruin, with a treasury depleted and without credit. From Díaz's first year as president (1876) to his last (1910) the federal revenue increased fivefold. The interest on the public debt was punctually paid. Banks, railways, harbours, lighthouses multiplied manifold. Imports and exports grew tenfold. Manufacturing industries of all kinds advanced. Education is obligatory; schools doubled during Díaz's administration; pupils increased from 193,000 to 778,000, and the amount spent on public schools from £200,000 to £1,000,000. The National University in the city of Mexico was re-founded in 1910. Since Díaz's time civil wars have done much to check progress; but another university was founded in 1922 at Mérida (Yucatán). The bulk of the people are, at least nominally, Roman Catholic, but the constitution of 1917 confirms the separation of church and state. No church can acquire landed property. There are seven archbishops and twenty-three bishops. The federal government supports a complete public health establishment, with a legion of artisans for the execution of works of public utility—schools, penitentiaries, hospitals, roads, drainage and sanitation of ports and cities, irrigation-works, &c. The administration of justice has been raised to the level of modern nations. From 1923 judges are appointed for life. The cities have modern drainage and sanitation, with most of the conveniences of Europe.

History of Mexico.—Apart from the Mayas (q.v.) in the southern parts of the country, the history of ancient Mexico exhibits two distinct and widely differing periods—that of the Toltecs and that of the Aztecs. Both were Nahuatl nations, speaking a language which survives in Mexico to this day. The 8th century is the traditional date when the Toltecs are related to have come from the north, from some undefined locality, bringing to Anáhuac its oldest and its highest native civilisation. Their capital they established at Tula, north of the Mexican valley. Their laws and usages stamp them as a people of mild and peaceful instincts, industrious, active, and enterprising. They cultivated the land, introduced maize and cotton, made roads, erected monuments of colossal dimensions, and built temples and cities, whose ruins in various parts of New Spain still attest their skill in architecture, and sufficiently explain why the name Toltec should have passed into a synonym for architect. They knew how to fuse metals, cut and polish the hardest stones, manufacture earthenware, and weave various fabrics; and to their

invention are assigned the Mexican Hieroglyphics (q.v.) and calendar. It is related that a severe famine and pestilence all but destroyed the Toltec people in the 11th century, and drove the survivors southward to Guatemala and Yucatán, carrying their arts of civilisation with them; and near the end of the next century, after their place had been taken by the rude Chichimecs, a fresh migration brought, among other kindred nations, the Aztecs into the land. Within two centuries and a half this last people had become predominant. But their rule was, in a great degree, a reversion to savagery. They were a ferocious race, with a religion gloomy and cruel, and they grafted upon the institutions of their predecessors many fierce and sanguinary practices. Thus they produced an anomalous form of civilisation, which astonished the Spaniards by its mingled character of mildness and ferocity. After wandering from place to place, the Aztecs founded about 1325 the city of Tenochtitlan, or Mexico; a hundred years later they had extended their sway beyond their plateau-valley, and on the arrival of the Spaniards their empire was found to stretch from ocean to ocean.

Their government was an elective empire, the deceased prince being usually succeeded by a brother or nephew, who must be a tried warrior; but sometimes the successor was chosen from among the powerful nobles. The monarch wielded despotic power, save in the case of his great feudal vassals; these exercised a very similar authority over the peasant class, below whom, again, were the slaves. Taxation appears to have been heavy in Mexico even then. The laws were severe, nearly every crime being met with capital punishment in some form; but justice was administered in open courts, the proceedings of which were perpetuated by means of picture-written records. The Mexicans apparently believed in one supreme invisible creator of all things, the ruler of the universe; but the popular faith was polytheistic, with a number of chief and many inferior divinities, each of whom had his sacred day and festival; whilst a crowd of nature-spirits peopled the hills and woods. At the head of the Aztec pantheon was the frightful Huitzilopochtli, the Mexican Mars. His temples were the most splendid and imposing; in every city of the empire his altars were drenched with the blood of human sacrifice, to supply victims for which the emperors made war on their neighbours or on any revolted territory, and levied a certain number of men, women, and children by way of indemnity. The victims were borne in triumphal processions, and to the sound of music, to the summit of the great pyramidal temples, where the priests, in sight of assembled crowds, bound them to the sacrificial stone, and, slashing open the breast, tore from it the bleeding heart and held it up before the image of the god, while the captor carried the carcass off to feast on it with his friends. In the years immediately preceding the Spanish conquest not less than 20,000 victims were annually immolated, including infants, for the propitiation of the rain-gods. These atrocities, originally referable to the entire absence of live-stock, were incongruously blended with milder forms of worship, in which fruits, flowers, and perfumes were offered up amid joyous outbursts of song and dance. According to the tradition, Quetzalcoatl, who delighted in these purer sacrifices, had once reigned among the Toltecs in the golden age of the world, but, being obliged to retire from earth, he departed by way of the Mexican Gulf, promising to return. This tradition accelerated the success of the Spaniards, whose light skins and long dark hair and beards were regarded as evidences of their affinity with the long-looked-for divinity. The Mexican priesthood formed a rich and powerful

order of the state, and were so numerous that Cortes found as many as 5000 attached to the great temple of Mexico. The education of the young of both sexes was entrusted to the priests and priestesses; and the sacerdotal class were thus able to exercise a widely-diffused influence, which, under the later rulers, was almost equal to that of the emperor himself. The women shared in all the occupations of the men, and were taught, like them, the arts of reading, writing, ciphering, singing in chorus, dancing, &c., and even initiated in the secrets of astronomy and astrology.

Cortes landed at Vera Cruz in 1519; the history of the conquest of the Aztec land is told at length in the article on that greatest of the *conquistadores*, who gave to Spain what for centuries remained her richest province. Before his energy, and the superior civilisation of his followers, the power of the native empire crumbled away. In 1540 Mexico was united with other American territories—at one time all the country from Panamá to Vancouver's Island—under the name of New Spain, and governed by viceroys (57 in all) appointed by the mother-country. The intolerant spirit of the Catholic clergy led to the suppression of almost every trace of the ancient Aztec nationality and civilisation, while the commercial system enforced crippled the resources of the colony; for all foreign trade with any country other than Spain was prohibited on pain of death. The natives were distributed as slaves on the various plantations, though they were also christianised and looked after by the Inquisition, whose last *auto-da-fé* was held in Mexico city as late as 1815. Mexico was regarded as simply a mine to be worked by the labour of its people for the benefit of Spain. Yet, notwithstanding these drawbacks, it ranked first among all the Spanish colonies in regard to population, material riches, and natural products. For nearly three centuries it may be said to have lain in sullen submission beneath its cruel conquerors' heel, till in 1810 the discontent, which had been gaining ground against the viceregal power during the war of the mother-country with Napoleon, broke into open rebellion under the leadership of a country priest named Hidalgo. After his defeat and execution in 1811 Morelos, another priest, continued the struggle till he shared the same fate in 1815; and a guerilla warfare was kept up until, in 1821, the capital was surrendered by O'Donojú (a Spaniard of Irish descent), the last of the viceroys. In the following year General Iturbide, who in 1821 had issued the *plan de Iguala*, providing for the independence of Mexico under a prince of the reigning house, had himself proclaimed emperor; but the guerilla leader Guerrero, his former ally, and General Santa-Ana raised the republican standard, and in 1823 he was banished to Italy with a pension. Returning the following year he was taken and shot, and the federal republic of Mexico was finally established.

For more than half a century after this (till 1876) the history of Mexico is a record of nearly chronic disorder and civil war. Within that period the country had fifty-two presidents or dictators, another emperor, and a regency; and in nearly every case the change of administration was brought about with violence, a respectable proportion of these great men being ultimately shot by some opposing faction. In 1836 Texas secured its independence, for which it had struggled for several years, and which Mexico was compelled to recognise in 1845. In that year Texas was incorporated with the United States; but its western boundary was not settled, and the Americans coveted a particular strip of territory, and sent troops to seize it. The war thus wantonly provoked was continued with great energy by both

parties until 1848, when peace was finally concluded after several bloody engagements had been fought, and the city of Mexico had been stormed and taken by the Americans under General Scott. As the result of this war Mexico was compelled to cede half a million square miles of territory to her powerful enemy. For the details of the war, see UNITED STATES, and SANTA-ANA. Under the latter also falls to be told so much as is necessary of the history of the next few years. After his fall in 1855, down to 1867, great confusion prevailed. In 1858 Benito Juárez (q.v.) became president, but his claims were contested by General Miramón—the head of the reactionary or clerical party—and the country was plunged in civil war. The acts of wanton aggression and flagrant injustice perpetrated on foreigners in Mexico during this period of internal disorder brought a fleet of English, French, and Spanish ships into the Mexican Gulf for the purpose of enforcing satisfaction. In 1861 the Spaniards disembarked a force at Vera Cruz; and this step was soon followed by the arrival before that city of the allied fleet. Preparations to advance at once upon the capital alarmed the provisional government, and brought about an armistice and a treaty regulating commercial intercourse between Mexico and the great European powers. This treaty was not confirmed by France, and the French troops retained occupation of the Mexican territory. In April 1862 the French emperor formally declared war against the government of Juárez; but the French never met with the welcome they expected from the people, and had to withdraw in 1867—mainly because of the jealousy of their action shown by the United States. Maximilian, Archduke of Austria, who had become emperor of Mexico under French auspices, was executed in the same year, and Juárez returned to practically absolute power. See JUÁREZ and MAXIMILIAN. On the death of Juárez in 1872, the chief-justice, Lerdo de Tejada, assumed the presidency, in which, after a revolution, he was succeeded in 1876 by Porfirio Díaz, one of the ablest of Mexican rulers. He was re-elected for the eighth time in 1910, but resigned under pressure of revolution in 1911, and died in 1915. Under his autocratic, if not tyrannical, rule the position of the republic steadily improved. A long period of revolutions, anarchy, and confused faction fights followed. General Madero, elected president in December 1911, was murdered in 1913, when General Victoriano Huerta assumed power, dismissed congress, and ruled practically as dictator. Relations with the United States were severely strained. American pressure secured the 'elimination' of Huerta, who resigned in 1914. The 'Constitutionalist' leaders, Venustiano Carranza and Villa, then fell out. In addition to these, Zapata and other would-be presidents pushed their fortunes. Carranza was generally recognised abroad in 1915, and in 1917 was elected under the new constitution. Friction with the United States was renewed. A revolution under General Álvaro Obregón resulted in the shooting of Carranza in 1920, and the succession of Adolfo de la Huerta, of Obregón (1921), and of General Calles (1924).

See histories by Prescott, Bancroft, Frost, Miss Hale (1891), Priestley (1923). For forced labour or slavery in the culture of henequen and rubber in Yucatán, and other depressing features, see Turner's *Barbarous Mexico* (1911), and Baerlein's *Mexico the Land of Unrest* (1913), both of whom deal severely with Díaz, Baerlein computing Díaz's victims at 30,000. For antiquities, see Lord Kingsborough's *Antiquities of Mexico*; Tylor's *Anahuac* (1861); Strebel's *Alt-Mexiko* (1885-89); Peñafiel's *Monuments of Mexican Art* (1890); Arnold and Frost's *The American Egypt* (1909); Rickards's *Ruins of Mexico* (vol. i 1910); Joyce's *Mexican Archaeology* (1914); Seler's *Amerikanische Sprach- und Altertumskunde* (Berlin).

5 vols. 1902-15); Spinden's *Study of Maya Art* (Camb., Mass., 1913); *Bulletin 28* of the Bureau of American Ethnology (1904); Lewis Spence's *Gods of Mexico* (1923); and other works. See also books by Enoch (1909, 1924), MacHugh (1914), and Trowbridge (1919); Lumboltz, *Unknown Mexico*; and the articles CORTES and LAS CASAS.

Mexico (CITY), the capital of the republic, is situated in the Federal District (not the state of Mexico), 7347 feet above the sea, at the lowest level of the great lacustrine basin (1400 sq. m.) of the Anáhuac plateau. The largest of the six lakes that occupy this hill-girt valley, Lake Tezcuco, amid whose waters, Venice-like, the city first rose, has now retired $2\frac{1}{2}$ miles to the north-west—partly filled up by drainage deposits. In the Aztec city the principal thoroughfares radiated from an immense central square, in which towered the great temple of Huitzilopochtli; and this arrangement is yet preserved in the modern capital. All the main streets converge on the Plaza Mayor, where the site of the old *teocalli* is occupied by the no less famous cathedral (1573-1657). The walls of

Chalco and Xochimilco, where steamers run, a few of the floating gardens for which the ancient city was celebrated. Attempts had long been made to drain the valley of Mexico. A tunnel through the lowest hills to the Tula River (5 miles), cut in 1607-8 by Martinez, proved insufficient, and the city was flooded from 1629 to 1634; and even an open cut through the mountains (1637-67), 10 miles long, never entirely fulfilled its purpose. Consequently the climate, which is naturally one of the healthiest in the world, became a constant danger to its inhabitants. The federal government finally undertook the work, and operations, begun in 1890 by two English companies, were completed in 1898. Extensive drainage and sanitation works have since been carried out. In the 20th century a sumptuous legislative palace, a national Pantheon for the ashes of the great men of Mexico, and a monument to perpetuate the heroes of the Independence have been built, and the university re-founded. Mexico has extensive factories for cotton, linen, paper, tobacco and cigars, pottery, silver-ware,

Cathedral, City of Mexico.

this imposing building, forming a cross 426 by 203 feet, alone cost nearly £400,000, and the interior, with its twenty chapels and elaborate ornamentation, much more. Built into the foot of one of the two open towers (218 feet) is the famous 'Aztec' (Toltec) calendar stone. Facing the cathedral is the Municipal Palace, and on the sides of the plaza are the National Palace (the old vice-regal residence), the national Monte de Piedad, the post-office, and the national museum. Other noteworthy buildings are the national picture-gallery and library, the school of mines, the mint, and the former palace of the Inquisition, now a medical college; and, mostly in secularised ecclesiastical edifices, there are also schools of law and engineering, a conservatory of music, and an academy of fine arts. There are fifty churches or more, including the cathedral of the American Episcopal mission. The principal streets are broad, clean, and well paved and lighted, with houses of stone gaily painted in bright colours. Among the monuments of the city are the noble Columbus monument (1877), the statue of Cuauhtemotzin, the last of the Aztec emperors, and that of the engineer Martinez (1883). In addition to the *alameda*, with its stately beeches, Mexico is remarkable for the extent and beauty of its *paseos*, or raised paved roads, planted with double rows of trees, which diverge far into the country from every quarter; and there are still on Lakes

cork, bricks, and soap—many of them due to foreign enterprise. Five great railways connect the city with New Orleans, St Louis, Missouri, Chicago, New York, as well as with the other cities of Mexico. Pop. (1921) 615,367.

Mexico, GULF OF, a basin of the Atlantic Ocean, is closed in by the United States on the north, by Mexico on the west and south, and its outlet on the east is narrowed by the jutting peninsulas of Yucatán and Florida, which approach within 500 miles of each other. Right in the middle of this entrance is planted the island of Cuba, dividing the strait into two—the Strait of Florida and that of Yucatán, the former connecting the gulf with the Atlantic Ocean, the latter with the Caribbean Sea. Sir John Murray calculated the area of the gulf at 716,200 sq. m. Over a fourth of this area the ocean-floor lies at a depth

of between 1000 and 2000 fathoms, while 58,000 sq. m. is deeper still. The shores, however, are very shallow—as it were, the broad rim of this central cauldron; the portion less than 100 fathoms deep exceeds 400,000 sq. m. The extreme length from SW. to NE. is more than 1100 miles. Of the numerous bays, the largest is the Bay of Campeche (Campeche). The coasts are mostly low and sandy or marshy, and are lined with numerous lagoons; the best of the few good harbours are those of New Orleans, Pensacola, and Havana. The gulf is visited from September to March by violent north-easterly gales called *nortes*. There are very few islands. The principal rivers it receives are the Mississippi and the Rio Grande del Norte. See GULF STREAM.

Meyer, CONRAD FERDINAND, Swiss poet and novelist, was born on 12th October 1825 at Zürich, near which he lived from 1877 till his death in 1898. He excels in character-drawing and in genre-pictures of descriptive work. His chief novels are *Jörg Jenatsch* (1876), a story of Switzerland in the 17th century, and *Der Heilige* (1880), two of the best historical novels of modern German literature. His power is also well shown in *Das Amulet*, *Der Schuss von der Kanzlei*, *Die Leiden eines Knaben*, *Die Hochzeit des Mönchs*, *Die Richterin* (1885), and *Die Versuchung des Pescara* (1887). His poetical skill is best displayed in the idyllic epic poem *Huttens letzte Tage*

(1872), in *Gedichte* (1882), and in *Engelberg*. There are Memoirs of him by Reitler (1885), Frey (1909), Langmesser (1905), and by his sister Betsy Meyer (1903).

Meyer, JOSEPH, publisher and industrial organiser, was born at Gotha, 9th May 1796, and died on 27th June 1856. A man of great energy and liberal ideas, he started several industrial enterprises, the most important being the issue of great serial works by subscription at low prices, such as the German classics, the *Konversationslexikon* (new ed. in 12 vols, 1924 *et seq.*; see *ENCYCLOPÆDIA*), *People's Library of Natural Philosophy, Historical Library*, &c. His publishing business, the 'Bibliographical Institute,' was founded at Gotha, but in 1828 was transferred to Hildburghausen, and in 1874 (by his son) to Leipzig.

Meyer, KUNO (1858–1919), Celtic philologist, born at Hamburg, came to Liverpool in 1884, became professor of Old Irish there in 1895, and in 1911 professor of Celtic in Berlin. He died at Leipzig.

Meyerbeer, GIACOMO, operatic composer, was born at Berlin, September 5, 1791. The son of Herz Beer, a wealthy Jewish banker, his name was originally Jakob Beer; the name Meyer was afterwards adopted from a benefactor, and the whole consolidated and Italianised. His musical genius was first shown on the pianoforte; at the age of seven he played in public Mozart's D minor concerto. He was received, when fifteen, into the house of the celebrated musician, the Abbé Vogler, at Darmstadt; with his fellow-pupil Weber he was on terms of the most intimate and lasting friendship. His earlier works, produced at Munich and Vienna, were unsuccessful, but in the latter city he obtained fame as a pianist, which might have stood against that of any rival had he chosen to rely on this talent. His ambition, however, was to succeed as a composer; and on the advice of Salieri he proceeded to study vocal composition in Italy. There Rossini's music had just taken the public by storm; and Meyerbeer, with his remarkable adaptability, after three years was able to produce operas in the new style, which at once gained a cordial reception; the last of these, *Il Crociato*, brought out at Venice in 1824, was received with acclamation, and the composer was presented on the stage with a laurel crown. From 1824 to 1831 he lived mostly in Berlin, married, and had two children, whose loss in infancy he keenly felt. He also applied himself, with the unremitting industry he evinced from boyhood, to a minute and comprehensive study of French opera. The result of this was seen in the production at Paris in 1831 of *Robert le Diable* (libretto by Scribe), in which a totally new style was evident. It had unparalleled success over all Europe, and made the fortune of the Paris opera—even Rossini was thrown rather into the shade. It was followed in 1836 by the *Huguenots*, which, with the assistance of a magnificent cast, almost eclipsed its predecessor. He was soon after appointed by the king of Prussia as his Kapellmeister at Berlin. Here he wrote the opera *Ein Feldlager in Schlesien*, the success of which was signalled by the first appearance of Jenny Lind. After long preparation, *Le Prophète* appeared at Paris in 1849, also with success, though it was not altogether to the mind of even friendly critics. The composer now ventured into a fresh field, the Opéra Comique; *L'Étoile du Nord*, given in 1854, carried the day in spite of the prognostications of French critics, and was succeeded in 1859 by *Le Pardon de Ploermel*, known in England as *Dinorah*. He was subsequently occupied with a musical drama, *La*

Jeunesse de Goethe, the setting of which M. Blaze de Bury, the author of the work, says he saw complete, but which has not hitherto come to light. In 1861 he set to work with his usual anxiety and fastidiousness on the production of *L'Africaine*, which had been in hand since 1838. But his delicate health gave way before his ceaseless labours, and he died at Paris, 2d May 1864. The opera had a triumphant reception a year later.

The magnificent praise of Fétis and Blaze de Bury is counterbalanced by the emphatic condemnation of Schumann and the savage attacks of Wagner. Wagner's main charge is that, inspired by no deeply rooted artistic principles, he made everything subsidiary to theatrical effect. His grand operas, splendid melodramatic spectacular works, hit the taste of the public.

See Lives by Pougin (1864) and De Bury (1868), and the article in Grove's *Dictionary*.

Meynell, ALICE CHRISTIANA (1850–1922), was sister of Lady Butler (see the article on Sir W. F. Butler). A devout Catholic, she became in 1877 the wife of Wilfrid Meynell, Catholic author and journalist. From 1875, when she published her first volume of poems, she approved herself a poet of exceptional grace and tenderness and a critic of insight and sympathy. She published several volumes of delicate verse, four or five books of essays (collected in 1914), anthologies, and selections (from T. G. Hake and Coventry Patmore). She and her husband befriended Francis Thompson. Their daughter VIOLA is a poet and novelist; their son EVERARD wrote a life of Thompson.

Mezereon. See DAPHNE.

Mézenc, MONT. See CÉVENNES.

Mézières, the capital of the French department of Ardennes, on a bend of the Meuse, 155 miles NE. of Paris. Strongly fortified by Vauban, in 1521 it was successfully defended by the Chevalier Bayard, with 2000 men, against 40,000 Spaniards under Charles V.; in 1815 held out for two months against the Allies; in the Franco-German war of 1870–71 capitulated after a frightful bombardment; and in 1914–18 was again in German hands. In its Flamboyant church (restored 1884) Charles IX. was married in 1570. Pop. 8000.

Mező-Tur, a town of Hungary, 40 miles by rail SE. of Budapest; pop. 26,000.

Mezquite, the name of two trees or shrubs, of the natural order Leguminosæ, sub-order Mimosoideæ, bearing pods filled with a nutritious pulp, found in Mexico, Texas, Arizona, &c. The Common Mezquite (*Prosopis juliflora*) is usually a large shrub (though sometimes 40 feet high), with stems often decumbent, and armed with strong straight spines. In dry seasons it exudes a great quantity of gum (*Gum Mezquite*), similar in quality to gum-arabic. The Curly Mezquite, Screw Bean or Tornillo (*Prosopis pubescens*), although only a shrub or small tree, is of great value in the desert regions of the western part of North America.

Mezzanine. See ENTRESOL.

Mezzofanti, GIUSEPPE, Cardinal, a remarkable linguist, was born at Bologna, 17th September 1774. He was ordained priest in 1797, and appointed to the chair of Arabic at Bologna; soon after he was deprived because of his inability to take the oath to the Cisalpine Republic, but was reinstated later. In 1831 he settled in Rome with the rank of Monsignore, and two years after succeeded Cardinal Mai as Keeper of the Vatican Library. In 1838 he was raised to the dignity of cardinal. He died 15th March 1849 at Rome. Mezzofanti's European reputation was founded, not on his writings, but on the almost miraculous extent of his linguistic acquirements. Towards the end of his life he understood and spoke fifty-eight different

tongues. As early, indeed, as 1820 Lord Byron called him 'a walking polyglot, a monster of languages, and a Briareus of parts of speech.' Yet he was not in the strict sense a critical or scientific scholar, or even otherwise a man of great intellectual power. See his *Life* by Russell (1857).

Mezzo-soprano. See SOPRANO.

Mezzotint. See ENGRAVING.

Mfumbiro, a mountain-range of Central Africa, west of Victoria Nyanza. The name is sometimes restricted to one or other of its volcanoes, the active Kirunga-cha-gongo (11,000 feet) and the extinct Muhavuru (13,600).

Mhow (*Mhau*), a British cantonment in Indore state, Central India, 13 miles by rail SW. of Indore city. It is 1919 feet above the sea. Pop. 32,000, two-thirds Hindus.

Miako. See KYÔTO.

Miall, EDWARD, an apostle of disestablishment, was born in 1809, and served as an Independent minister at Ware, and afterwards at Leicester, down to 1840, when he founded the *Nonconformist* newspaper. In 1844 he helped to establish the British Anti-state Church Association, known later as the Liberation Society, and sat in the House of Commons for Rochdale, 1852-67, and for Bradford, 1869-74. On retiring he was presented with ten thousand guineas. He died at Sevenoaks, 29th April 1881. See the *Life* by A. Miall (1884).

Miasma. See MALARIA.

Miautsé, or MIAO-TSU, an aboriginal hill-tribe of southern China, who have contrived to maintain a practical independence and many curious local usages. They consist of numerous clans, inhabiting mainly Szechwan and the borders of Yun-nan. Some of them own Chinese sway; other tribes are absolutely independent. They are smaller than the Chinese, and unlike in features as in character. Physique and language indicate their affinity with the Annamese, Siamese, and various other inhabitants of the Indo-Chinese peninsula.

Mica, an important group of rock-forming minerals, of hardness of about 2, characterised by their perfect cleavage in one direction—the laminae being flexible and elastic. They are hydrous aluminium silicates with potassium (more rarely sodium or lithium), magnesium, or iron. Some species contain fluorine. All crystallise in monoclinic forms which approximate closely to hexagonal and rhombic crystals. *Muscovite* or potash mica is a silicate of alumina and potash, with some of the latter occasionally replaced by soda and small quantities of magnesia, ferrous oxide, and fluorine. It is seldom colourless, but usually yellowish, brownish, or greenish. The lustre is pearly or almost metallic. The thin plates are generally transparent. They were formerly much used in setting objects for the microscope, and are still for lamp-chimneys, fronts of stoves, and the like (as less liable than glass to break with sudden changes of temperature), for the mounts of natural history objects which are to be put in spirit (being more easily bored than glass), and in electrical apparatus (mica being a non-conductor). Plates of muscovite often a yard across are found near Lake Baikal, at Acworth in New Hampshire, and in China. Large plates also occur in Sweden and in Norway, and masses of the mineral are met with in Cornwall. In Siberia, China, Peru, and elsewhere it is used for window-panes. In India small pictures are frequently painted in distemper on mica. Muscovite occurs as one of the essential constituents of ordinary granite, gneiss, and mica-schist. It is also an ingredient of many other plutonic rocks and crystalline schists, but is not a primary con-

stituent of volcanic rocks: where present in the latter it is as an alteration-product. *Sericite* is a talc-like variety of muscovite, not uncommonly met with as a constituent of certain schistose rocks, to which it imparts a silky lustre on the planes of foliation. *Damourite*, somewhat like sericite, is also a variety of muscovite which occurs occasionally in schistose rocks. *Lepidolite* or lithia mica is a silicate of alumina with potash and lithia; white, rose-red, or violet as a rule, but sometimes greenish; does not occur in measurable crystals, but in irregular plates and tables, and now and again in scaly, granular, or compact aggregates. In Moravia a massive granular lepidolite is found with a fine reddish-violet colour. Like jasper, lapis-lazuli, &c., lepidolite is made into ornaments; as a rock-forming mineral it is of small account. Another lithia mica containing iron is called *Zinnwaldite*. *Phlogopite*, a magnesium mica, rich in potassium, with variable amounts of fluorine and hydrogen, and little iron, occurs chiefly in metamorphic rocks, and is found less frequently than biotite in igneous rocks. *Biotite* is iron-magnesium mica, rich in potassium, often containing much titanium, and varying considerably in the proportion of iron and magnesium. In most biotites (*merozones*) the plane of the optic axes lies in the plane of symmetry; in others (*anomites*) it is at right angles to it. Biotite is generally black or dark brown, less often yellow or green. It possesses strong pleochroism. Most 'black micas' are biotites. In microscopic section biotites usually show numerous inclusions of small crystals of apatite and zircon. Round the latter the biotite is stained a darker colour. These 'halos' have been shown by Professor Joly to be due to the presence in the zircon of radio-active substances, the diameters of the halos agreeing with the distance to which particular emanations can transmit their energy. Biotite is widely distributed alike in igneous and metamorphic rocks, chiefly in the more acid varieties of the former, in the intrusive granites, diorites, and syenites, and the equivalent lava-form rocks, rhyolites, andesites, and trachytes; it is less common in basaltic rocks, although locally abundant in their plutonic equivalents, the gabbros and peridotites. Biotites are of common occurrence in many varieties of gneisses and schists. *Lepidomelane* is a magnesia mica rich in ferrous and ferric oxides. It occurs in felspathic igneous rocks poor in magnesia and relatively rich in iron oxides. The biotites are much more readily decomposed than the muscovites, being often altered into chloritic minerals with epidote and calcite. *Paragonite* or soda mica, an aluminous silicate of soda, occurs chiefly in certain crystalline schists, and is known only in the form of small white or colourless scales. It closely resembles muscovite, from which it can only be distinguished chemically.

MICA-SCHIST is, next to gneiss, one of the most abundant of the crystalline schists. It consists of alternate layers of mica and quartz, but is sometimes composed almost entirely of the thin and shining plates or scales of mica, and from this it passes by insensible gradations into phyllite, as this in turn passes into clay-slate. The quartz occurs pure in thin layers like vein-quartz, thinning off and swelling out abruptly. Sometimes it appears as irregular swollen-shaped lumps round which the folia of mica are arranged. The mica is usually muscovite, but occasionally it is biotite. Many accessory minerals are found in mica-schist, especially garnets: others are schorl, kyanite, hornblende, andalusite, beryl, &c. In many places the mica-schist has a finely corrugated or wavy structure.

Micah, or MICAHIAH, as the name is given in Jer. xxvi. 18 (*Micayah*—i.e. 'Who is like unto Jah?') Vulg. *Micheas*), the sixth in order of the

twelve minor prophets (third in LXX., after Hosea and Amos), is described as 'the Morashtite'—i.e., a native of Moresheth Gath in the lowland of south-western Judah near Eleutheropolis, and as having prophesied during the reigns of Jotham, Ahaz, and Hezekiah, more particularly during that of Hezekiah, and so as a younger contemporary of Isaiah, Hosea, and Amos. He is carefully to be distinguished from the Micah or Micaiah of 1 Kings, xxii. 8 *et seq.*, the son of Imnah, who was a prophet of the northern kingdom, contemporary with Elijah, in the reign of Ahab. The Book of Micah is described in the superscription as the word of the Lord that came to Micah which he saw concerning Samaria and Jerusalem. It consists of a collection of detached prophecies the phraseology of which is in some cases extremely obscure; no chronological order or other method of arrangement is discernible. The opening passage (i. 2-8) contains a threatening of the divine judgment against Samaria on account of her idolatry; but the rest of the book, as might be expected in a Judæan prophet, seems to relate entirely to the southern kingdom, and probably was not spoken or written until after the fall of the kingdom of Israel in 722 B.C. The oracle contained in i. 9-16, relating to Judah and Jerusalem, is best interpreted in connection with the Assyrian invasions, threatened and actual, of the Judæan lowland, shortly after that date; it is rendered obscure for the English reader by a number of plays upon words which can be appreciated only in the original language. Micah was not, like his contemporary Isaiah, a politician, but he lived (though not in the capital) in the same religious and social environment, and took practically the same view of the position of the people of Jehovah. His whole activity was directed to a work of moral reformation; his book consists of unsparing denunciations of mercenary prophets, rapacious and corrupt priests, cruel and oppressive nobles, and a treacherous, fraudulent, godless people. He went beyond Isaiah in his threatenings, for he did not regard even the holy city as inviolable, but, anticipating Jeremiah by a hundred years, foretold the destruction of Jerusalem and the Temple (see iii. 12; iv. 9, 10; some critics regard iv. 11-13, a passage which seems to take the opposite view, as an interpolation). Like Isaiah Micah pointed the hopes of the people of Jehovah forward, in noble language, to the establishment of the kingdom of righteousness and peace based on the knowledge and fear of the Lord; he also looked forward to the kingship of a Messiah of the house of David, who (in this Micah was original) like his great ancestor should come forth from Bethlehem. Some critics refer chapters vi. and vii. to an anonymous author in the reign of Manasseh; Wellhausen and many others give a still later date to chapter vii. 7-20.

See works by Cheyne (1882); Taylor (1891); J. M. P. Smith, *International Critical Commentary*; and books cited at HOSEA.

Michael. See ANGEL, MOHAMMED; and for the Emperor, BYZANTINE EMPIRE.

Michael (St) and St George. ORDER OF, was instituted by George III. in 1818 to commemorate the acquisition of the Ionian Isles (q.v.) and Malta (q.v.), and to be conferred on natives of those islands. But later its scope was widened so as to include distinguished members of the colonial service. It has three classes, Knights Grand Cross, Knights Commanders and Companions, with collar and badge, and star. The cross is of white enamel, with St Michael on the obverse and St George on the reverse; the ribbon blue, with scarlet stripe; the motto *Auspicium melioris ævi* ('A pledge of better times').

Michaelis, JOHANN DAVID, was born 27th February 1717 at Halle, the son of Christian Benedict Michaelis (1680-1764), a theologian and orientalist. After completing his studies at Halle he travelled to England; in 1745 he began to teach at Göttingen, and in the following year was appointed professor of Philosophy. He took an active part with Haller in the formation (1751) of the Göttingen Academy. In 1750 he had been elected to fill the chair of Oriental Languages in addition to that of Philosophy. He died on 22d August 1791. Michaelis was a man of vast attainments, especially in history, archaeology, and natural science; and to him belongs the credit of being one of the first to study the biblical narratives as an integral part of oriental history.

His chief works are *Einleitung in die göttlichen Schriften des Neuen Bundes* (2 vols. 4th ed. 1788; Eng. trans. by Marsh, 4 vols. 1802); *Mosaïsches Recht* (2d ed. 5 vols. 1776-80; Eng. trans. by Dr Alexander Smith, 1814); *Spicilegium Geographiæ Hebræorum* (1769-80); *Orientalische und exegetische Bibliothek* (1775-85); *Supplementa ad Lexicæ Hebræica* (6 vols. 1784-92); and numerous others. See his *autobiographic Lebensbeschreibung* (ed. by Hassencamp, 1793).

Michaelmas Daisy. See ASTER.

Michaelmas Day. On this festival, which was instituted in the year 487 in honour of St Michael and all Angels, is elected the Lord Mayor of London. In England, too, Michaelmas Day is one of the four quarterly terms on which rents are paid; and among the curious manorial rites connected with this season may be mentioned the Lawless Court kept on King's Hill, near Rochford, in Essex, on the Wednesday morning following Michaelmas Day. The Michaelmas goose is an ancient institution. For Michaelmas term, see TERM.

Michel, FRANCISQUE (1809-87), born at Lyons, became in 1839 professor in the Faculté des Lettres at Bordeaux, and earned a reputation by researches on Norman history, French *chansons*, argot, the Basques, and the history of medieval commerce. Among his books were *Histoire des Races Maudites* (1847); *Histoire des Hôtelleries, Cabarets, Hôtels Garnis* (1851-54); *Les Écosseis en France et Les Français en Écosse* (1862); and *A Critical Inquiry into the Scottish Language* (1882), a misleading book.

Michel, LOUISE (1833-1905), came from Haute Marne to Paris as a teacher, and, condemned to death for her share in the Commune (1871), was transported to New Caledonia. Freed by the amnesty of 1880, she was soon in trouble with the home authorities as a persistent agitator. She gave anarchist lectures, and published novels and *mémoires*.

Michelangelo, often MICHAEL ANGELO. Michelangelo Buonarroti, the most distinguished sculptor of the modern world, was born on March 6, 1475. His father, Ludovico di Leonardo Buonarroti Simoni, was a poor gentleman of Florence, who, though bankrupt in fortune, did not lack the consideration which is paid to ancient lineage. When the sculptor was born, his father was *podestà* or mayor of Caprese and Chiusi, two townships in Tuscany. He returned to Florence when his term of office was expired, and the child was entrusted to the fostering care of a stonemason's wife at Settignano, where Ludovico owned a small property. The boy's enthusiasm for art revealed itself at an early age, and, though he was sent to the school of Messer Francesco di Urbino to learn the elements, his best energies were devoted to drawing. To his father's aristocratic prejudice sculpture seemed a calling unworthy of a gentleman. The lad, however, was resolute, and in 1488, while yet only thirteen years of age, he entered the *bottega* of Domenico Ghirlandajo, to whom he was bound

apprentice for three years. None was ever more fortunate than Michelangelo in the time and place of his birth. From his boyhood he was familiar with the masterpieces of Donatello, and he joined his contemporaries in making a pilgrimage to the convent of the Carmine, where he studiously copied the supreme examples of Masaccio's art. By Ghirlandajo he was recommended to Lorenzo de' Medici, and entered the school which the 'Magnifico' had established in his garden on the Piazza. Here was gathered together, under the care of Bertoldo, a priceless collection of antiques, and here Michelangelo encountered what proved the most enduring influence of his life. His talent was not long in arresting the notice of Lorenzo, who henceforth gave him a room in his house and a seat at his table; and to the beneficence of his patron he owed the acquaintance of Poliziano and many of the most learned of the day. To this period belong two interesting reliefs. In the 'Battle of the Centaurs' (now in the Casa Buonarroti at Florence) the classical influence of Lorenzo's garden is strikingly apparent. In truth it has little of the dignified calm which distinguishes the work of Phidias and his contemporaries; the style of a later period was its inspiration; but it reveals the lasting characteristics of Michelangelo's genius. The inexhaustible variety of pose, the straining muscles, the contorted limbs, which mark the artist's mature work, are already visible. A marvellous contrast to the 'Centaurs' is the 'Madonna,' conceived and executed in the spirit of Donatello, which without a suggestion of movement is quiet and harmonious in composition, and though not consciously antique is far more classical.

In 1492, when Michelangelo had spent some three years in his house, Lorenzo died, and the school which had conferred so great benefits upon art was straightway dissolved. Piero, Lorenzo's son and successor, it is true, retained for a time the services of Michelangelo, but he is said to have treated him with scant courtesy; and Michelangelo fled to Bologna. Nor did he here wait long for a patron; Gianfrancesco Aldrovandi commissioned him to execute a statue. In Bologna the sculptor lingered for a year; then he once more (in 1495) returned to Florence. It was during this sojourn in his native city that he fashioned the marble 'Cupid' to which he owed his first introduction to Rome. Baldassare del Milanese persuaded him to give the work the air of an antique by burial, and despatch it to Rome. Here it was purchased by Cardinal San Giorgio, who, though he speedily discovered the fraud which had been put upon him, was quick to detect the talent of the sculptor who had tricked him. He therefore summoned him to Rome, and on June 25, 1496 Michelangelo arrived for the first time in the Eternal City. The influence of Rome and the antique is easily discernible in the 'Bacchus,' now in the National Museum at Florence; it is modelled with an elegance and restraint which are evidence of the hold which the classical tradition, as interpreted by the Græco-Roman sculptors, had upon Michelangelo. To the same period belongs the exquisite 'Cupid' of the South Kensington Museum. The 'Pietà,' which is now in St Peter's, was executed in 1497, but presents an amazing contrast. There is in it a touch of the middle ages, a suggestion of realism which is wholly at variance with the antique ideal. But it is beautifully composed, the drapery is handled with a masterly breadth, and the body of the dead Christ is an epitome of anatomical research.

For four years the sculptor remained in Rome, perpetually urged to return to Florence by his father, who, though he objected to his son's craft as unbefitting his station, was nothing

loth to profit by the wealth which was the reward of artistic success. Michelangelo went back; and Soderini, who was then gonfaloniere, permitted him to convert into a statue the colossal block of marble upon which Agostino d'Antonio had been at work many years before, and out of the irregular block grew the celebrated 'David.' The sculptor was compelled to modify his composition on account of the shape and size of his material. Indeed, it is characteristic of this titan's impetuous genius that obstacles were ever an incentive. His 'David' is the Gothic treatment of a classic theme. The influence of the antique is obvious, but the personal touch of the sculptor is also apparent (especially in such details as the treatment of the hands). The figure is modelled with strength and simplicity; the surface is not furrowed by an endless series of lines; there is no parade of anatomical knowledge; in pose and composition there is a stately grandeur, a dignified solemnity, which do not for an instant suggest that the artist was hampered by material difficulties. Indeed, so far from being a *tour de force*, it is a complete, well-ordered achievement. In 1504 it was placed upon its pedestal in the Piazza de' Signori, whence it was removed in 1873 to the Academy of Arts. Michelangelo's sojourn in Florence was a period of great activity. A second 'David' (this time of bronze) was commissioned and sent to France, where all trace of it is lost. The sculptor also designed two marble reliefs, one of which passed into the possession of Sir George Beaumont, and is now at Burlington House. The 'Holy Family of the Tribune' and the 'Manchester Madonna' in the National Gallery belong to the same time, and prove that Michelangelo had not wholly neglected the art of painting. His genius, however, was essentially plastic. He had far more interest in form than in colour; indeed, in his hands pictorial art was but an opportunity for the vigorous modelling of the human form. The zeal of Soderini, the gonfaloniere, in the cause of art inspired the scheme of decorating the Great Hall of the Council. For one wall Leonardo da Vinci was commissioned to design a fresco; a second was entrusted to Michelangelo. The latter chose as his subject an incident in the war of Pisa, and executed a cartoon which Vasari with devout exaggeration proclaims to have been of divine rather than of human origin. A body of soldiers were represented bathing; their camp has been attacked by the enemy, and they are hastening to seize their arms and repulse the assault. The motive is admirable, and gave the artist scope for the variety of pose and the violent action in which he took peculiar delight. The fresco was never completed, and on the return of the Medici to Florence the cartoon was removed to the hall of their palace, to which painters were permitted unrestrained access. The result was that over-zealous admirers of Michelangelo cut the cartoon to pieces. The original is lost as irretrievably as the masterpieces of Zeuxis and Apelles; and our impression of it is obtained from literary sources, from the engravings of Marcantonio and Agostino Veneziano, who reproduced single groups, and from a suspicious copy at Holkham Hall.

In 1503 Julius II. succeeded to the pontificate, and, being not merely a warrior but a patron of the arts as well, he lost no time in summoning Michelangelo to Rome. In Michelangelo the sturdy pope met his match. The two men, indeed, were not unlike in temperament. Each was endowed with the extraordinary vigour of mind and body which was the best characteristic of the Renaissance. But both had the defects of their qualities; Michelangelo no less than Julius was violent and overbearing; the sculptor could as little brook opposi-

tion as the pope, and their dealings were continually interrupted by bitter quarrels and recriminations. It is impossible to accept Vasari's anecdotes as statements of the literal truth, but there is no doubt that they have solid foundation in fact. Had Michelangelo known the misery and disappointment which were in store for him, he might well have hesitated before obeying the summons of Julius. The pope commissioned the sculptor to design his tomb, and thus began what Condivi aptly calls *la tragedia della sepoltura*. For forty years Michelangelo clung to the hope that he would yet complete the great monument in honour of Pope Julius and his own genius. But intrigue and spite were too strong for him. Other demands were continually made upon his energy, and the sublime statue of Moses is the best fragment that is left to us of the tomb of Julius. However, at the outset both pope and sculptor were full of enthusiasm. The plans were approved and the work would have at once proceeded had not the sculptor one day asked audience of the pope in vain. In a sudden fit of temper Michelangelo left Rome, and the entreaties of the pope availed not to procure his return. After much fruitless negotiation they met at Bologna, and, with the generosity that was characteristic of both, were instantly reconciled. Michelangelo, as a pledge of renewed friendship, commenced a statue of Julius II., which was cast in bronze and placed over the gate of San Petronio (afterwards melted down and converted into a cannon). Michelangelo followed the pope to Rome, eager to resume his work upon the monument. In the meantime, however, Bramante, if Vasari's account be true, had poisoned the pope's mind against the sculptor; instead of being allowed to devote himself to the monument, which he deemed the work of his life, he was ordered to decorate the ceiling of the Sistine Chapel with paintings. In vain he protested that sculpture was his profession, in vain he urged Raphael's higher qualifications for the task; the pope was obdurate, and in 1508 Michelangelo began the work for which his training had ill adapted him. However, he set himself resolutely to the toil, and in four years achieved a masterpiece of decorative design. The flat oblong space of the ceiling is divided into nine compartments, each of which contains an incident drawn from the Old Testament. The lunettes above the windows, the spandrels, as well as the ressaunts between the lunettes, are filled with heroic figures. The designs are admirably accommodated to the space they are intended to fill, and the broad effect is one of harmony and homogeneity. It is only when you analyse the composition and examine each compartment by itself that you realise the superhuman invention, the miraculous variety of attitude and gesture, which place this marvellous work among the greatest achievements of human energy. Michelangelo, however, had not forgotten the monument of Pope Julius, and no sooner had he finished his work in the Sistine Chapel than he returned with eagerness to the tomb. But once again his favourite project was interrupted. In 1513 Pope Julius II. died, and, though he had commanded the cardinals Santi Quattro and Aginense to see that his monument was completed in accordance with his expressed wishes, the cardinals were thrifty men, and demanded of Michelangelo another and a more modest design. This was furnished, but before the work could be undertaken Pope Leo X. had despatched Michelangelo on business of his own to Florence. Leo was of the Medici family, and professed no interest in the tomb of his predecessor; his whole anxiety was to do honour to his ancestors by the adornment of Florence. He therefore commissioned Michelangelo to rebuild the façade of the church of San Lorenzo and enrich it

with sculptured figures. The master reluctantly complied, and set out for Carrara to quarry marble. Even here the pope would not permit Michelangelo to work his will, but urged him to leave Carrara and seek what material he needed at Serravezza, which lay in Leo's own territory. In vain the sculptor insisted that the marble was of inferior quality, and that to convey it to Florence roads must be cut through mountains and laid upon stakes over marsh-land and swamp. Leo X. was deaf to reason, and for eight years Michelangelo was forced to devote himself to toil as idle as that of Sisyphus; from 1514 to 1522 his artistic record is a blank. Nor were the next years fruitful of achievement. The sculptor remained in Florence still working on the tomb of Julius and building the Sacristy of San Lorenzo. In 1528 the unsettled state of his native city turned him again from the practice of his art. He devoted himself heart and soul to the science of fortification, and when in 1529 Florence was besieged Michelangelo was foremost in its defence. The city was forced to surrender in the following year, and for some time Michelangelo, fearing treachery, lay in concealment. His safety, however, being assured, he resumed his work upon the tombs of the Medici, and completed the monuments to Giuliano and Lorenzo de' Medici, which are among the greatest of his works. In 1533 yet another compact was entered into concerning Pope Julius's ill-fated sepulchre; it was at last determined to reduce it to a mere façade, and Michelangelo would doubtless have carried it to completion had he not been once again commissioned to adorn the Sistine Chapel with frescoes. After a delay of some years he began in 1537 to paint 'The Last Judgment.' The design was finished and displayed on the Christmas-day of 1541, and was the master's last pictorial achievement. In the following year he was appointed architect of St Peter's, and devoted himself to the work with loyalty and devotion until his death, which took place on the 18th February 1564.

Michelangelo is by far the most brilliant representative of the Italian Renaissance. He was not only supreme in the arts of sculpture and painting, but was learned in all the learning of his age, a poet of powerful individuality, an architect and military engineer. From an artistic point of view his was by far the greatest personality, his the most potent influence, the modern world had seen. His debt to the antique was immense, yet it must be remembered that he knew only the decadence of classical art; had he seen the masterpieces which have since been brought to light, it is possible that his style might have been largely modified. But, though in the finest examples of his art classical influence is conspicuous, he was rarely able to exclude his personality. As he was violent in his life, so there is ever a touch of violence in his art. He is making, as it were, an emphatic protest against the dark ages which lay behind him; he is discovering to the world the utmost possibilities of the reawakened arts. There is generally to be observed in his work a profound learning, an extraordinary knowledge of perspective and foreshortening, a firm conviction that there is nothing in heaven or on earth that art cannot express. At beauty Michelangelo does not aim. Grandeur, sublimity, power, these are his themes. And he recurs to them again and again with the persistence which characterises a man of transcendent genius. Both Donatello, who came before him, and Raphael among his contemporaries, were more richly endowed than he with the artistic temperament. Neither the one nor the other was wont to overstep the limits of art. Their ambition was to attain perfection; they did not chafe against the restraints imposed by beauty and

simplicity. But Michelangelo, though their inferior in art, had a far greater, if less governable, genius. He was not content to model a perfect statue, to paint a perfect form; he was ever striving to throw himself and his intelligence into marble or on to canvas. And so, though his works will be ranked till the end of time among the masterpieces of the world, he is neither for sculptor nor for painter the most valuable model. As an influence he was more potent than any of his contemporaries, and it can hardly be said that his influence was wholesome. The Flemish and Dutch painters, who visited Italy in the 16th century, carried home with them his love of distorted limbs and twisted draperies, but failed to catch a breath of his invention and vigour. It is easy, even for the mediocre, to parody a strongly-marked talent.

The master's career is not without irony. His genius was plastic; by temperament and training he was a sculptor, and yet frescoes were the only works he was destined to bring to fulfilment. He has left behind him, it is true, not a few grandiose statues, such as the 'Moses,' but none of his elaborate designs for sculptural monuments was ever completed. His career, indeed, was, until he came for the last time to Rome, a prolonged struggle against fate and his patrons. Time after time his own projects were set aside at the pleasure of a pope. For this his own waywardness and excitability were in some measure to blame, and throughout his life he seems to have been unable to attack any enterprise except at fever-heat. His sonnets, the composition of which he, unlike the rest of mankind, reserved for his old age, possess the same qualities as his statues. Just as his 'David' was torn from the marble, so his verses are rough-hewn out of the language. In all of them it is meaning rather than form that is sought after. Dr Johnson's criticism of a production of Bentley's is precisely applicable to them. 'They are the forcible verses of a man of a strong mind, but not accustomed to write verse.' The best of them were inspired by his friendship for the accomplished Vittoria Colonna, the widow of the Marchese di Pescara. Michelangelo's life was untouched by the passion of love, and his one romance belongs to his old age. He is said to have met Vittoria for the first time in 1538, and until her death, which took place in 1547, the closest ties of friendship bound them. Her loss was the severest blow which ever fell upon him. He painted her portrait, and this honour he conferred on none other save Tommaso Cavaliere, for whom he cherished a romantic attachment and to whom also he addressed sonnets.

Michelangelo's character was a strange medley of conflicting qualities. Though kind and loyal to those who depended on his care—as is proved by his untiring interest in his nephew and his devotion to Urbino, his faithful servant—he showed himself resentful and even suspicious to his enemies. He could brook no opposition to his wishes, and he mercilessly attacked those who dared to withstand him. But he lived in an age of treachery and intrigue, and much may on this count be forgiven him. He loved solitude and a simple life. From his earliest youth he was an eager student of literature, and applied himself with peculiar devotion to Dante and Petrarch. Though feared and attacked by the envious among his contemporaries, he earned his full meed of praise during his lifetime, and at his death universal honour was paid to his memory.

See Lives by Vasari and Condivi. The best edition of the letters is Milanese's *Lettere di Michel Angelo* (1873). The sonnets have been edited by Cesare Guasti, *Rime di Michelangelo Buonarroti* (1863), and translated into English by J. A. Symonds. Of modern and critical biographies there is no lack—those, for example, by Springer, Grimm, Von Scheffler (1892), Ollivier, Gabriel Thomas, Justi, Thode, Frey, J. A. Symonds (1892), Holroyd (1903;

new ed. 1911), Horne (translating Condivi, 1904), Davies (1909), and Rolland (trans. by Lees, 1912).

Michelet, JULES, a great French historian, was born a printer's son at Paris, 21st August 1798. After a brilliant course of study under Villemain and Leclerc, he became at twenty-three a professor of History in the Collège Rollin. Later he lectured at the Collège Sainte-Barbe and the École Normale, and after the revolution of 1830 was given an important post at the Archives, became assistant to Guizot at the Sorbonne, and tutor to the Princess Clémentine. In 1838 he was elected to the Academy, and at the same time became professor of History at the Collège de France. Already he had made his name known by admirable handbooks on French and on modern history, and commenced the monumental work which was to give him an illustrious place among great historians, his *Histoire de France* (24 vols. 1833-67; new ed. 19 vols. 1879), the labour of about forty years. Other works were *Origines du Droit Français cherchées dans les Symboles et Formules du Droit Universel* (1837), *Mémoires de Luther* (1845), and *Procès des Templiers* (1841-51). Michelet had a great dislike for priests, but especially for the Jesuits, and he now plunged into controversy with all the impetuosity of his nature and eloquence, bringing to bear upon the enemy at once all his powers of sarcasm and all his unrivalled knowledge of history. Three books were the fruits of his polemic: *Des Jésuites*, written in conjunction with Edgar Quinet (1843); *Le Prêtre, la Femme, et la Famille* (1845); and *Le Peuple* (1846). Next followed his famous *Histoire de la Révolution* (7 vols. 1847-53; centenary ed. 5 vols. 1889), which is not a good history with all its eloquence and enthusiasm. Before its conclusion Michelet had lost his office by refusing to take the oath of allegiance to Louis Napoleon. Henceforth he lived mostly in Brittany and in the Riviera, buried in his gigantic literary labours. A series of books of a novel kind, full of rhapsodic eloquence and more valuable as literature than as science, were *L'Oiseau* (1856), *L'Insecte* (1857), *La Mer* (1861), and *La Montagne* (1868). Other books of unusual interest were *L'Amour* (1858), *La Femme* (1860), *La Sorcière* (1862), and *La Bible de l'Humanité* (1864). The little book, *Nos Fils* (1869), was a plea for compulsory education. Michelet's great history brings down the story of France to the outbreak of the great Revolution. The second instalment continues it to the close of the Revolution. In the last years of his life he set himself to complete his task, and thus bequeath a great continuous history to France, but he did not live to carry it beyond Waterloo (3 vols. 1872-75). He died at Hyères, 9th February 1874.

Michelet ever treats history from a personal point of view, and his imagination is prone to bring into undue relief striking figures and dramatic scenes and incidents. Thus his work is a series of tableaux, as these were visible to the eyes of a man of genius, full of prejudices for and against his puppets, and destitute of the sense for historical perspective. Yet the whole stands out a masterpiece of genius, instinct with life, and the wide range of historical literature must be ransacked for episodes surpassing his treatment of Joan of Arc or the Templars, or the luminous geographical survey of France with which the works opens.

Michelson-Morley Experiment. See RELATIVITY.

Michigan (Chippewa-Indian *Mitchi Sawgyegan*, 'Great Lake,' originally applied to both Lakes Huron and Michigan), the third in size of the five great fresh-water lakes of North America, and the

only one lying wholly in the United States, having Michigan on the N. and E., and Wisconsin and Illinois on the W. It is about 335 miles long, and from 30 to 88 broad; the mean depth is 325 feet. It has the same elevation as Lake Huron (with which it is connected by the Strait of Mackinaw)—581 $\frac{1}{2}$ feet above sea-level; this is 20 $\frac{1}{2}$ feet lower than Lake Superior, and 8 $\frac{1}{2}$ feet above Lake Erie. Its surface area is 22,450 sq. m., or 1350 less than that of Lake Huron; but its drainage area—37,700 sq. m.—is 6000 sq. m. greater than its neighbour's. There is a neap-tide of 1 $\frac{1}{2}$ inch, and a spring-tide of about 3 inches. The shores of Lake Michigan, which are guarded by a number of lighthouses, are for the most part low; the annual erosion amounts to about 5 feet. Its principal harbours are those of Chicago, Milwaukee, Racine, Escanaba, and Grand Haven. It has important fisheries; whitefish (*Coregonus*) and trout are largely exported.

Michigan, one of the northern tier of states of the American Union, the twenty-second in area and seventh in population, is in 41° 42' to 48° 20' N. lat., and 82° 25' to 90° 32' W. long. It has an area of 57,980 sq. m.; 1114 sq. m. are occupied by 5173 small lakes, while the surface of 179 islands and islets, from one acre upwards, measures about 633. The coast-line in navigable lake waters is 1624 miles. The state is bounded on the S. by Indiana and Ohio; on the E. by Lake Erie, Detroit River (properly Strait), Lake St. Clair, St. Clair River, Lake Huron, and St. Mary's River, beyond all which lies the province of Ontario, Canada; on the N. by Lake Superior, on the SW. (upper peninsula) by Wisconsin, and on the W. by Lake Michigan. From its north-western point at the mouth of Montreal River to the extreme south-east on Maumee Bay is about 500 miles. It is sometimes called the Peninsular State, from its formation in two great peninsulas, the upper and lower, or northern and southern. The upper has an extreme length of 318 and width of 164 miles, the lower of 277 and 197 miles; the latter includes the Huron Peninsula, or the 'thumb' of the 'mitten,' in eastern Michigan, and the small Leelanaw Peninsula in the north-west. The eastern part of the other, looking toward St. Mary's River, is sometimes called St. Mary's Peninsula. Keweenaw Peninsula, bearing the great copper-mines, stretches far north into the waters of Lake Superior; and on the south, near Mackinac Island, is the little but picturesque St. Ignace Peninsula. The upper region is mostly rugged, broken, rocky, and comparatively barren, though teeming with mineral wealth; but hopeful beginnings of agriculture have been made in the eastern half of it. In the north-west, near Lake Superior, is the highest land in the state, among the hills known as the Porcupine Mountains (1830 feet above the sea). The famous Mineral range passes south of this, from Keweenaw Point south-westward into Wisconsin; but it is merely a gentle swell from both sides, nowhere really mountainous. No part of the lower peninsula is more than 1780 feet above sea-level; and the mean height is only 160 feet above the environing waters of the lakes. The highest part of Detroit is but 73 feet above the river at this point, and the uplift of a few feet in the adjacent river and lake beds would flood a thousand square miles of Michigan soil. This soil is mainly formed by the glacial drift, in alternated clay, sand, and gravel beds, supplying all the chemical constituents of a good soil, and enabling the growth of all crops adapted to this climate. The mean annual temperature of the state is 48° F. (summer, 72°; winter, 24°); the annual rainfall is 32.2 inches. Both peninsulas, with occasional exceptions of swamps or small prairies, were originally covered with dense forests, the products

of which have proved exceedingly valuable. The geology of the state is highly interesting; it represents every rock series known from the oldest strata to the top of the Carboniferous. In the west of the upper peninsula, on the Wisconsin border, are the Laurentian, and on either side and eastward the Huronian formations, in which are the great deposits of iron ore. The Mineral range is of volcanic rock, with older strata tilted upon its sides. Farther eastward are the long belts of the Lower Silurian, curving from Green Bay through the St. Mary's Peninsula. The lower peninsula is compared, geologically, to a nest of wooden dishes. Its centre is a coal-bearing area. In succession beyond, and in mighty sweeps around the central tract, are the upturned edges of other Carboniferous strata, then the Devonian formations, and finally the Lower Helderberg group of the Silurian. In the Michigan salt group are the rich brine wells of the Saginaw valley; in the Marshall or Waverley are the Huron grindstones, quarried on the shore of Lake Huron; and other groups yield valuable mineral products.

Copper and iron are the chief minerals, copper-mining dating from 1845. The great Calumet and Hecla copper-mines, probably the largest in operation, are on the Keweenaw Peninsula. The copper is of a quality nowhere surpassed, and for some purposes unequalled. Iron ore is mined mainly in Marquette county. Coal and salt are got. Silver is mined to some extent, while gypsum appears in immense deposits, mostly in Kent county. Portland cement is also found in large quantities, and building-stones abound in both peninsulas. Glass sand is found in the extreme south-east of the state; and lime, brick, tiles, and the like are made easily and cheaply in many parts. There are many mineral springs, the waters of some of which have a commercial value.

Lumbering and wood manufactures constitute interests of some importance, maple, beech, and birch figuring largely. Consequent upon the extensive destruction of forests, attempts are at present being made to effect reforestation. Agriculture employs a considerable proportion of the population, the production of maize, potatoes, sugar-beet, and wheat being of some importance. From the fruit areas of the south and south-west come large supplies of cucumbers, apples, grapes, and strawberries. The dairy-produce is worthy of note.

The motor-car industry is centred in Michigan, especially in Detroit, where the factories of Henry Ford are the most noteworthy. There is also a large output of machinery, chemicals, and furniture, and the state ranks seventh in shipbuilding.

The commerce of the state is very great, and is promoted by three ship-canal—one among the shallows at the head of Lake St. Clair, another near the head of St. Mary's River, at the Sault de Ste. Marie, and another on the Keweenaw Peninsula, known as the Portage Lake Canal. The commerce of Detroit is large, especially the export trade, consisting mostly of grain, pork, wool, and copper. There are other ports of entry, at Port Huron, Grand Haven, and Marquette. The railways in the state have about 10,000 miles of track. Popular and higher education has been liberally developed; the illiterates form only 3 per cent. of the population, and most of them are foreign born. Besides the state university at Ann Arbor, there are denominational colleges and state normal schools; the agricultural school, the school for the blind, and reform school for boys at Lansing; the deaf and dumb institute at Flint, and an industrial home for girls at Adrian. Other principal state institutions are several asylums for the insane, an asylum for insane criminals, and the Soldiers' Home at Grand

Rapids. There are state prisons at Jackson and Marquette, and houses of correction at Detroit, Marquette, and Ionia.

History.—The Michigan country was probably visited by Jean Nicolet in 1634, at the Sault de Ste Marie, where the first permanent white settlement was made by Father Marquette in 1668 for a Jesuit mission. Detroit was founded in 1701 by a French colony under Cadillac. The country passed to the English in 1760, and to the United States in 1796; it was again occupied by Great Britain in 1812, but was recovered by the Americans the next year. It formed a part of the North-west territory, erected in 1787; became a part of the Indiana territory in 1802, was organised as Michigan territory in 1805, and admitted as a state in 1837. Pop. (1800) 551; (1840) 212,267; (1880) 1,636,937; (1900) 2,420,982; (1920) 3,668,412. Detroit, with a population of over 1 million, has always been the chief city; Grand Rapids (137,643) is second, and Flint (91,599) third. Other cities are Saginaw, Sault Ste Marie, Marquette, Bay City, Muskegon, Jackson, Kalamazoo, Port Huron, Lansing (the capital), Battle Creek, Manistee, Ishpeming, Menominee, Ann Arbor, Adrian, &c.

Michigan City, a city of Indiana, on Lake Michigan, 38 miles by water ESE. of Chicago. It has a good harbour, contains a college, a state prison, and railway-shops, and manufactures cars, refrigerators, furniture, &c. Pop. (1860) 3320; (1890) 10,704; (1920) 19,457.

Mickiewicz, ADAM, the greatest of Polish poets, was born near Novogrodek on 24th December 1798, and educated at Vilna. In 1822, whilst teaching Polish literature at Kovno, he published his first collection of poems, full of the inspirations of Polish national life. Two years later he was banished to the interior of Russia for being concerned in the formation of a students' secret society. In 1825 he paid a visit to the Crimea, whose beauties he celebrated in a series of exquisite sonnets. Before quitting Russia in 1829 he published three epic poems, *Dziady* (1823–27), on the religious commemorations of their ancestors by the Slav races, and *Konrad Wallenrod* (1828; Eng. trans. 1841, 1925) and *Grazyna* (1827), the last two drawn from the struggle between the Lithuanians and the Knights of the Teutonic Order, and both glowing with patriotic feeling. From Russia Mickiewicz passed through Germany (where he visited Goethe and awakened the old Olympian's warm admiration) and France to Italy and Rome. In 1834 appeared his masterpiece, the epic poem *Pan Tadeusz* (Master Thaddeus; trans. 1886, 1917)—a most admirable delineation of Lithuanian customs and manners, traditions, ideas, and beliefs, and Lithuanian character, including fine poetical descriptions of the gloomy primeval forests and of the scenery of the country. After teaching for a while at Lausanne, Mickiewicz was appointed professor of the Slavonic Literatures at Paris in 1840; but three years later he was deprived of his chair, having given offence to the government of the day by political utterances in his lectures. For some years he lived a hard and unsettled life—in 1848 he was in Italy, helping to organise the Polish legion that fought side by side with the Italian republicans at Rome—until in 1852 Louis Napoleon appointed him a librarian in the Arsenal Library at Paris. He died 28th November 1855 at Constantinople, whither the French government had sent him to organise a Polish legion to fight against Russia. Mickiewicz is pre-eminently the national poet of the Poles, and next after Pushkin the greatest of all the poets of the Slavs.

His collected works were issued at Paris in 11 vols. (1860–61), at Leipzig in 5 vols. (1862–69), and at Lemberg,

in 4 vols. (1885–93). See *Life* by his son Ladislas (French, 1888; Polish, 4 vols. 1890–94); and a life with analysis of his work, and translations, by Monica M. Gardner (1911).

Mickle, WILLIAM JULIUS, translator of the *Lusiad*, was born in Langholm manse, Dumfriesshire, in 1734. He was educated at Edinburgh High School, failed in business as a brewer, and next went to London to make a living by writing. In 1765 he published his would-be Spenserian poem, *The Concubine* (in its next edition entitled *Syr Martyn*), and so prepared the way for his version rather than translation of the *Lusiad* of Camoens (1771–75), which he completed during four years' seclusion in a farmhouse. In 1779 he went to Lisbon as secretary to Commodore Johnstone, but his last years were spent in London, where he died in 1788. Of his other works none are now of importance. His ballad of *Cumnor Hall*, which suggested to Scott the romance of *Kenilworth*, is poor stuff, but the delightful song, 'There's nae luck about the house,' is long since safely assured of its immortality. An attempt has been made to ascribe this song to the ill-fated Greenock poetess, Jean Adam (1710–65), but her claim will not bear serious examination. See *Athenæum* for January 27, 1877. The best edition of Mickle's poems is that edited, with a Life, by the Rev. John Sim (1806).

Micmacs, a tribe of Algonquin Indians, the first with whom the English came in contact; they remained hostile to the English and their colonies till 1760. They now number from 3000 to 4000, and are mostly in Nova Scotia, Newfoundland, and New Brunswick. See Rand, *English Micmac Dictionary* (Halifax, 1888).

Microbe, **Micrococcus**. See BACTERIA, GERM.

Microcline. See FELSPAR.

Microcosm and **Macrocosm**. The belief of the ancients that the world or kosmos was animated, or had a soul (see ANIMA MUNDI), led to the notion that the parts and members of organic beings must have their counterparts in the members of the kosmos. Thus, in a hymn ascribed to Orpheus, the sun and moon are looked upon as the eyes of the animating godhead, the earth and its mountains as his body, the ether as his intellect, the sky as his wings. The natural philosophers of the 16th century—Paracelsus at their head—took up this notion anew in a somewhat modified shape, and considered the world as a human organism on the large scale, and man as a world, or kosmos, in miniature; hence they called man a *microcosm* (Gr., 'little world') and the universe itself the *macrocosm* ('great world'). With this was associated the belief that the vital movements of the microcosm exactly corresponded to those of the macrocosm, and represented them as it were in copy. From this it was an easy transition to the further assumption, that the movements of the stars exercise an influence on the temperament and fortunes of men (see ASTROLOGY).

Microcosmic Salt is used in blowpipe analysis, and may be prepared by mixing concentrated solutions of phosphate of soda and chloride of ammonium. It has the composition $\text{NaNH}_4\text{HPO}_4 \cdot 4\text{H}_2\text{O}$.

Microlestes, a name given to one of the early fossil representatives of Mammals, in the order Multituberculata, probably allied to Monotremata (q.v.). Only the small teeth are known, from the Trias of England and Germany.

Micrometer (Gr. *mikros*, 'little'; *metron*, 'measure') is an instrument used for the measurement of minute distances and angles. Its different forms, depending on different principles, may be divided into two sections, according as they are

applied to physics or astronomy. Of the former section are the Vernier (q.v.) and the Micrometer Screw, the latter instrument being merely a screw with a very regular thread, and a large round head, which is carefully graduated, generally to sixtieths, and furnished with an index. It is easily seen that if a complete turn of the screw advance its point $\frac{1}{60}$ of an inch, a turn sufficient to pass the index from one graduation to another will only advance it $\frac{1}{3600}$ of an inch, &c. This is the micrometer used in the construction and graduation of instruments. Of those applied to astronomical purposes the most simple is a short tube, across the opening of which are stretched two parallel threads, which are moved to or from each other by screws. These threads are crossed by a third perpendicularly, and the whole apparatus is placed in the focus of a lens. The distance of two stars is found by adjusting the two parallel threads, one to pass through the centre of each star, taking care that the threads are placed perpendicular to the line joining the stars, and finding how many turns and parts of a turn of the screw are required to bring the wires to coincide. The angle of position of two stars is also obtained by turning round the instrument till the third wire, which is normally horizontal, bisects both stars, and reading off on the circumference the arc passed over. *Fraunhofer's suspended annular micrometer* consists merely of a steel ring surrounded by a flat rim of glass, and the position of the star is deduced from the time when it crosses the ring and its path while within it. The Abbé Rochon substituted for the wire micrometer one made of two prisms of rock-crystal or Iceland spar, capable of double refraction.

Microphone. This instrument, invented in 1878 by Professor Hughes, does for faint sounds what the microscope does for matter too small for sight. One of the most sensitive substances for microphonic action is willow-charcoal, plunged in a state of white heat into mercury. The theory is that in a homogeneous conductor of electricity the compressions and dilatations of the molecules balance each other, and no variation of current ensues; while, with a state of fine grained non-homogeneity of the conductor, variations of pressure on the conductor produce variations in its conducting power, and thus induce variations in the strength of the electric current traversing it; and these variations of current, when the current passes through a second similar conductor, induce corresponding variations in its molecular stresses, which may act upon the surrounding air and give rise to sonorous waves; or the variations in the current may be detected by the Telephone (q.v.). One form of microphone consists of a piece of mercury-tempered carbon, an inch long, placed vertically between two carbon-blocks hollowed to receive its ends; wires connect the blocks with the battery and with the receiver by which the sounds are to be heard. 'A piece of willow-charcoal,' says the inventor, 'the size of a pin's head is sufficient to reproduce articulate speech.' Two nails laid parallel, with wire connections, and a third nail laid across them, make a simple form of microphone. A few cells of any form of battery may be used. Many useful applications of the microphone have been made or suggested. See WIRELESS TELEPHONY.

Microscope (Gr. *mikros*, 'small;' and *skopeō*, 'I see') is an instrument for enabling us to examine objects which are so small as to be almost or quite undiscernible by the unaided eye. Its early history is obscure; but, as it is quite evident that the property of magnifying possessed by lenses must have been noticed as soon as they were made, we are quite safe in attributing its existence in its simplest form to a period considerably anterior

to the time of Christ. It is generally believed that the first compound microscope was made by Zacharias Jansen, a Dutchman, in the year 1590, and was exhibited to James I. in London by his astronomer, Cornelius Drebbel, in 1619. It was then a very imperfect instrument, colouring and distorting all objects. For many years it was more a toy than a useful instrument, and it was not until the invention of the achromatic lens by Chester Moor Hall (1729) and John Dollond (1752-57), and its application to the microscope by Lister and others, that it was set on the way to reaching the advanced position it now occupies among scientific instruments.

An object to be magnified requires simply that it be brought nearer to the eye than when first examined; but as the minimum focal distance of the eye ranges from 6 inches to 14 inches—10 inches being the average minimum focal distance—it follows that a limit to the magnifying power of the eye is attained whenever the object to be examined is brought too near. If, however, we blacken a card, and pierce a hole in it with a fine needle, and then examine a minute object, as, for instance, the wing of an insect held about an inch from the card, we shall see it distinctly, and that, too, magnified about ten times its size. This is explained by the fact that the pin-hole limits the divergence of the pencil of rays from each point of the object, so that the eye can converge it sufficiently on the retina to produce a distinct impression, which is faint; and did not the blackened card exclude all other light it would be lost. If we now remove the blackened card without either moving our eye or the object under examination, it will be found that the insect's wing is almost invisible, the unassisted eye being unable to see clearly an object so near as one inch; thus demonstrating the blackened card with the needle-hole in it to be as decidedly a magnifying instrument as any set of lenses.

In fig. 1 AB is a double convex lens, in front of which, between it and its focus, K, but near that focus, we have drawn an arrow, EF, to represent the object under inspection. The cones drawn from its extreme points are representative rays of light, diverging from these points and falling on the lens. These rays, if not interrupted in their course by the lens, AB, would be too divergent for the eye to bring them to a focus upon the retina (see EYE). But after traversing the lens, AB, they travel, if the object be sufficiently near the focus, K, in lines which are nearly parallel, or which apparently diverge from points, such as C, D, not nearer to the eye than the least distance of distinct vision, which is, for most individuals, about ten inches. Suppose the lens is as close as may be to the eye, and that the object, EF, is brought up to it to such a distance that the virtual image, CD, is at 10 inches' distance from the eye; and let us further suppose that the focal length of the lens is such (see LENS)

Fig. 1.

that the image, CD, is ten times, linearly, as great as EF; then the eye, instead of vainly striving to see the small object, EF, near K, will seem to perceive distinctly an image ten times as great

linearly, and situated at the convenient distance, H. The magnification of the lens is independent of the eye, and is the relation between the size of the image and that of the object. When one of these is at an infinite distance and the other at a principal focus, the magnifying power depends on the position of the eye, and is the ratio between the apparent size of the object at any given distance and that of the virtual image as seen with the aid of the lens; this may be seen to increase as the eye is withdrawn to a greater distance, especially when the one eye is used to look at the object, say a page of print, and the other to look through the lens; but the greatest retinal image is formed when the lens is close to the eye.

We have supposed the whole of the light to enter the eye through the lens, AB (fig. 1); but so large a pencil of light passing through a single lens would be so much distorted by its spherical figure, and by the chromatic dispersion of the glass, as to produce a very indistinct and imperfect image. This is partly rectified by applying a stop to the lens, so as to allow only the central portion of the pencil to pass. But, while such a limited pencil would represent correctly the form and colour of the object, so small a pencil of light is generally unable to illuminate the whole of the magnified picture with any adequate degree of brilliancy. Dr Wollaston was the first to overcome this difficulty, which he

Fig. 2.

achieved by constructing a doublet (fig. 2), which consists of two plano-convex lenses, having their focal lengths in the proportion of 1 to 3, and placed at a distance best ascertained by experiment. Their plane sides are placed towards the object,

and the lens of shortest focal length next the object. By this arrangement the distortion caused by the first lens is corrected by the second, and a well-defined and illuminated image is seen. Dr Wollaston's doublet was further improved by Mr Holland, who substituted two lenses for the

Fig. 3.

first in Dr Wollaston's doublet, and retained the stop between them and the third. This combination, though generally called a triplet, is virtually a doublet, inasmuch as the two lenses only accomplish what the anterior lens did, although with less precision, in Dr Wollaston's doublet. In this combination (fig. 3) of lenses the errors are still further reduced by the close approximation of the lenses to the object, which causes the refraction to take place near the axis, and thus we have a still larger pencil of light transmitted, and have also a more distinct and vivid image presented to the eye.

Simple Microscope.—By this term we mean an instrument by means of which we view the object through the lens directly. These instruments may be divided into two classes—those simply used in the hand, and those provided with a stand or frame, so arranged as to be capable of being adjusted by means of a screw to the exact focal distance, and of being moved over different parts of the object.

Fig. 4.

The single lens used may be either a bi-convex or a plano-convex. When a higher power is wanted a doublet, such as we have already described, may be employed, or a Coddington lens, which consists (fig. 4) of a sphere in which a groove is cut and filled up with opaque matter. This is perhaps the most convenient hand lens, as it matters little, from its spherical form, in what position it is held. In the simple microscope single or combined lenses may be employed, varying from a quarter to two inches focal length. There are many different

kinds of stands for simple microscopes made, but, as they are principally used for dissection, the most important point next to good glasses is to secure a firm, large stage for supporting the objects under examination. When low powers alone are used the stage-movements may be dispensed with; but when the doublet or triplet is employed some more delicate adjustment than that of the hand is necessary.

Compound Microscope.—In the compound microscope in its simplest form the observer does not view the object directly, but an inverted real image or picture of the object is formed by one lens or set of lenses, and that image is looked at through another lens. The compound microscope consists of two lenses, an object and an eye lens; but each of these may be compounded of several lenses playing the part of one, as in the simple microscope. The eye-lens, or ocular, is that placed next the eye, and the object-lens, or objective, that next the object. The objective is generally made of two or three achromatic lenses, while the eye-piece generally consists of two plano-convex lenses, with their flat faces next the eye, and separated at half the sum of their focal lengths, with a diaphragm or stop between them. Lenses of high power are so small as to admit only a very small beam of light, and consequently what is gained in magnifying power is often worthless from deficient illumination. Various devices have been employed to overcome this difficulty. The light may be concentrated by achromatic condensers placed beneath the stage, or the curvature of the lens may be such as to allow as large a number of divergent rays as possible to impinge upon it. Such a lens is said to have a large 'angle of aperture,' the angle of aperture being that made by two lines converging from the margins of the lens to its focal point. Lenses, termed 'immersion lenses,' are also constructed, of such a curvature that when they are immersed in a drop of liquid placed over the object light is admitted under a high angle of aperture. With an immersion lens there is high magnifying power with sufficient illumination.

The accompanying diagram (fig. 5) explains one manner in which the complete compound microscope acts. We have here represented the triple achromatic objective, consisting of three achromatic lenses combined in one tube, in connection with the eye-piece, which now consists of the field-glass, FF, in addition to the eye-glass, EE. The function of the field-glass, FF, is that the rays of light from the object tend, after traversing the objective, to form an image at AA; but coming in contact with the field-glass, FF, they are bent, and made to converge at BB, where a real image is formed, at which place a stop or diaphragm is placed to intercept all light, except what is required to form a distinct image. From BB the rays proceed to the eye-glass, EE, exactly as they do in the simple microscope. The real image formed at BB is therefore viewed as an original object through the eye-glass, EE. The lens, FF, is not essential to a compound microscope; but as it is quite evident that the rays proceeding to AA would fall exterior to the eye-lens, EE, if it were removed, and only a part of the object would

Fig. 5.

thus be brought under review, it is always made use of in the compound microscope. In use, the microscope is first lowered so as to bring the object-glass as near as may be to the object; the real image is then formed, or tends to be formed, above BB; the whole is then gradually lifted away from the object, during which operation the real image descends towards BB; when it reaches BB, the virtual image is first distinctly seen, at AA; the instrument is then 'in focus.'

The theory of the conditions which must be fulfilled in order to obtain accurate images of extremely minute objects with very fine markings is a very elaborate one; a good sketch of Professor Abbe's investigations will be found in the 8th edition of Carpenter's *The Microscope*. The calculation of the corresponding curvatures which must be given to the component lenses and of the special characteristics of the kinds of glass from which they must respectively be made is the subject-matter of a very recondite branch of mathematics. In the early days of antiseptic surgery Professor Lister (Lord Lister, q.v.) had to walk by inference and not by sight, for his 'germs' had never been seen in the existing microscopes; the very special kinds of glass from which the required lenses could be made were themselves not obtainable until the year 1887 (Abbe-Schott glasses, Jena); now the modern science of bacteriology is a commonplace of medical study with the aid of modern microscope lenses.

A mirror is placed under the stage for reflecting the light through the object under observation. This method of illumination by transmitted light is used when the object is transparent. When opaque, light is reflected on the object by a bull's-eye lens, called a condenser. Of late years considerable attention has been devoted to lateral illumination, which enables objects of a degree of minuteness inaccessible to the microscope used with transmitted light to be seen as bright points against a dark background (Ultra-microscopy).

The best instruments are supplied with six or seven object-glasses, varying in magnifying power from 20 to 2500 diameters. The eye-pieces supplied are three in number, each of which consists of two plano-convex lenses, between which a stop or diaphragm is placed, half-way between the two lenses. As the magnifying power of

a compound microscope depends on the product of the magnifying powers of the object-glass and the eye-piece, it follows that its power may be increased or diminished by a change in either or both of these glasses. In the mechanical arrangements it is of importance to have the instrument so constructed that, while every facility is afforded for

Fig. 6.

observation and easy adjustment, there should also be great steadiness. These ends are achieved in various ways, of which fig. 6 is one of the

simplest: *a*, brass stand, supported on three feet; *b*, mirror supported on trunnions; *c*, diaphragm, pierced with circular holes of various sizes, to regulate the admission to the object of reflected light from the mirror; *d*, stage-plate, on which the object is placed; *e*, screw, with milled head for fine adjustment; *f*, the object-glass or objective; *g*, brass tube in which the body of the instrument is moved, so as to effect the coarse adjustment; *h*, the eyepiece, or ocular. Recently Mr Bertram has developed methods for the examination of exceedingly minute objects by the use, instead of ordinary light, of ultra-violet rays of extremely short wavelengths (*Super-microscope*).

For a more complete account of the different kinds of microscopes, and the various purposes to which they are applied, see Quekett *On the Microscope* (1885); Carpenter, *The Microscope* (8th ed. 1901); works by Hogg and Beale; Spitta's *Microscopy* (1920); Cotton and Mouton, *Les Objets Ultramicroscopiques* (1907).

Microtome, an instrument for cutting thin sections of portions of plants and animals preliminary to their microscopic examination. The objects to be cut are imbedded in some material such as paraffin or celloidin, or frozen in gum, which makes the slicing of minute or delicate objects readily feasible. The cutting used to be done by holding the prepared object in one hand and wielding a razor in the other, but this method, apt to yield sections of unequal or insufficient thinness, has given place to the use of some form of microtome, which is at once quicker and more effective. These instruments are quite simple devices by which a sliding razor slices a fixed but adjustable object, or by which the object is made to move across the edge of the razor.

Midas, a common name of the ancient Phrygian kings, most famous of whom is Midas, son of Gordius and Cybele, and pupil of Orpheus. For his kindness to Silenus he was promised by Dionysus whatever he should ask, and in his folly he asked that everything he touched should become gold; but, as the very food he touched was at once changed into gold, he was soon fain to implore the god to take back his fatal gift. He was told to bathe in the sources of the Pactolus, and from that day to this its sands have yielded grains of gold. Once, when Apollo and Pan were engaged in a musical competition on the lyre and the flute, Midas was called in to decide between them. He gave the palm to Pan, whereupon Apollo changed his ears to those of an ass. He concealed the deformity under his Phrygian cap, but could not hide it from his barber, who felt so heavy the burden of a secret he dared not reveal that he dug a hole in the ground and whispered into it, 'King Midas has ass's ears.' He then filled up the hole, and his heart was lightened; but out of the ground sprung up a reed which ever whispered the shameful secret to the breeze.

Middelburg, capital of the Dutch province of Zeeland, in the island of Walcheren, and 4½ miles by rail N.E. of Flushing. In former times it was one of the leading mercantile cities of the United Provinces, sending many ships to the East and West Indies, and the Levant (Thomas Cromwell was one of its merchants); but its commercial importance has greatly declined, except for an active inland trade in corn, potatoes, and madder. Cotton-factories represent its only industry of note. The town-house, founded by Charles the Bold in 1468, is adorned with twenty-five statues of counts and countesses of Holland and Zeeland. A once celebrated abbey is now used as offices. The museum of the Academy of Sciences contains a telescope made by Lippershey, a native of the town, inventor of the instrument. Pop. 18,000.—Middelburg in the Transvaal (pop. 5000), 250 miles

W. of Lourenço Marquez, is a trading and mining centre; Middleburg in the Cape Province (4000) is 250 miles N. by W. of Port Elizabeth.

Middle Ages is the collective term for the centuries that intervened between the close of classic times and the dawn of the modern epoch. The term does not apply to Asiatic history, except, in part, in the Orient. By general acceptance, the middle ages are considered to begin after the overthrow of the Western Empire of Rome in 476, and to terminate at the Reformation, in the first quarter of the 16th century, or even earlier, in the last half of the preceding century, when printing was invented, America discovered, and the Renaissance (q.v.) of Learning was in full career. See the *Cambridge Medieval History* (1912 *et seq.*).

Middle Level. See BEDFORD LEVEL.

Middlesbrough, a great iron and steel manufacturing and shipbuilding and shipping centre in the North Riding of Yorkshire, is a municipal, parliamentary, and county borough, and capital of the district of Cleveland. It is on the south bank of the Tees near its mouth, 15 miles by rail ENE. of Darlington, 50 N. of York, and 246 N. by W. of London. In 1829 the site was occupied by a solitary farmhouse surrounded by marshy land; the town owes its remarkably rapid growth partly to the extension thither (in 1830) of the Stockton and Darlington Railway, but mainly to the discovery of iron ore in the adjoining Cleveland hills (1850) and its nearness to the Durham coalfield. Another industry—that of boring salt—was added in 1886. There are iron and steel works, blast-furnaces, shipbuilding and ship-repairing yards, marine engineering works, bridge works, iron pipe and tube works, iron, steel, copper, and brass foundries, chemical works and wire works; factories for oil and grease, fertilisers, paving blocks and bricks, steel hoops, firebricks, and much else. The Cleveland district contributes nearly one-half of the total production of pig-iron in the United Kingdom. The London and North Eastern Railway has a dock (26 acres); and there are wharves and dry docks appurtenant to the shipbuilding and repairing yards of the river. In addition the corporation is constructing docks for small vessels and a public landing-stage. The Tees Conservancy Commission (1852) has by dredging and the construction of two breakwaters at the mouth of the river and the erection of training walls made of waste slag from the local ironworks converted the Tees into a navigable river capable of accommodating the largest vessels. The South Gare breakwater was begun in 1863, and took twenty-four years to build, being over 2½ miles long. The North Gare breakwater has been completed to a length of about three-quarters of a mile. The parish church of St Hilda was erected in 1840 on the site of a monastic cell supposed to have been established 686 A.D. and destroyed by the Danes about 857. A chapel was erected soon after 1066, and by a grant of Robert de Brus the church of Middlesbrough was founded in 1120, which church was affiliated to Whitby Abbey, and demolished in 1660. There are besides Anglican and Nonconformist churches a Catholic cathedral and a Jewish synagogue. The town-hall and municipal buildings, of 13th-century style, are by repute architecturally the finest public buildings in the North of England. Among other public buildings are a public library and museum, and several hospitals. The Constantine Technical College, chiefly for metallurgy, is about to be erected. A transporter bridge (1911), for pedestrians and vehicles, connects Middlesbrough with Port Clarence. The Albert Park (72 acres) was given in 1868 by Mr H. W. F. Bölekow, the first mayor and member of parliament;

Marton Hall and Park (134 acres), now the 'Stewart Park,' was presented in 1923 by Councillor Stewart of Middlesbrough. In the Victoria Park, opposite the municipal buildings, there are statues of Mr Vaughan, the founder of the Cleveland iron trade, and Sir Samuel A. Sadler, the first Conservative member of parliament for Middlesbrough, a public-spirited benefactor. Mr Bölekow's statue stands in Zetland Place. The first governing body, 'The Middlesbrough Improvement Commission,' was established in 1841; the borough was incorporated in 1853, and created a county borough in 1889. From 1867 it returned one member to parliament, since 1918 two. Middlesbrough (not Middlesborough) is the local and official spelling, the charter having spelt it so from the first. Pop. (1921) 131,070.

Middlesex, a small county in the south of England, bounded on the N. by Hertfordshire, on the E. by Essex, on the W. by Buckinghamshire, and on the S. by the Thames and the county of London. The northern boundary is irregular, having been determined originally by the estates of the abbey of St Albans and the bishopric of Ely. On the east the river Lea and on the west the Colne and the Brent form the natural boundaries. Although the area is but 233 sq. m., the population is large (1,253,164 in 1921), which is accounted for by the neighbourhood of the county and city of London. We first hear of Middlesex as a sub-kingdom dependent on Essex. Its position between the territory of the East Saxons and that of the West Saxons accounts for the name. The greater part of the surface was covered with a forest, of which Enfield Chase and Hampstead Heath are relics; but it was traversed by the great road which crossed the Thames, probably by a ford at Westminster, and led north-westward under the name of the Watling Street. The population was very sparse, and it has been remarked that no castle stood within its boundary, and no great abbey except that of Westminster. After the Conquest we hear little of the county until 1101, when Henry I. granted it in farm to the citizens of London. The position of Middlesex thenceforward until the passing of the Local Government Act in 1888 was wholly peculiar. For a rent of £300 per annum the citizens had the appointment of the sheriff and all other regal rights. It was usual for the sheriffs of the city to hold the office on alternate days, whence the legal form, 'the sheriffs of London and sheriff of Middlesex.' The whole body of citizens held the office, and their nominees were strictly speaking not high but sub-sheriffs, while the Lord Mayor was Lord-lieutenant. Under this régime, as is well known, the county shared in the prosperity of its great neighbour, and became at last so populous that by the act already named those portions of it which lay nearest the Thames and the city were severed from it, and, with certain districts of Kent and Surrey, were incorporated into a new 'county of London' (q.v.). At the same time a sheriff for Middlesex and a lord-lieutenant were appointed by the crown, and a singular usage which had subsisted for more than seven centuries ceased to obtain. Middlesex has (since 1918) ten members of parliament.

The low rolling undulations consist of London Clay, topped here and there with river-drift, in which indications of early human life have been found. There is but little tillage, except for market-gardens, and a great part of the county consists of grazing land, being covered largely with villa residences, surrounded in many places with large parks. Brickfields occupy the western border, and the number of large suburban villages—without, however, any important town—is remarkable. Brentford, Uxbridge, and Ealing are

to the west of London, and the first-named is usually reckoned the county town. Northward are Harrow, with its school, Enfield, and Tottenham. Eastward are Highgate and Hornsey. London, it may be well to note, was never in Middlesex.

Middlesex, and especially its eastern border, was the scene of many conflicts with the Danes. During the Wars of the Roses, Barnet on the northern verge gave its name to the battle on the neighbouring Hadley Common, where in 1471 the King-maker was defeated and slain. The principal mansions are Hampton Court (see HAMPTON), Sion House (see ISLEWORTH), and Osterley, near Hounslow, a handsome building by Robert Adam.

Middle Temple. See INNS OF COURT.

Middleton, a town of Lancashire, on the Irk, 3 miles W. of Oldham and 6 NNE. of Manchester. An old town which in 1791 received a charter for a weekly market, it was incorporated as a municipal borough in 1886, the borough area including the townships of Middleton, Tonge, and Alkrington, with parts of Hopwood and Thornham. The staple industry is cotton. It has an interesting church, a grammar-school (1421; re-founded 1572), library, &c. Pop. (1851) 5740; (1921) 28,290.

Middleton, a town of Ireland, 13 miles by rail E. of Cork. At the college (1696) Curran was educated. Pop. 3200.

Middleton, CONYERS, a famous controversialist, was born at Richmond in Yorkshire in 1683. He studied at Trinity College, Cambridge, and in 1706 obtained a fellowship, which a prudent marriage soon enabled him to resign. About 1722 he became librarian to the university, and in his later years was presented to the living of Hascombe in Surrey. He died at his seat at Hildersham in Cambridgeshire in 1750. All his life through Middleton was busy in controversy, and in bitterness of tone and ferocity of temper he was a match for any of his contemporaries. His first antagonist was the redoubtable Bentley; but, though at first successful, he was afterwards obliged to apologise to him for libel. His later controversies were theological in character, and in these he gained great distinction, but left his own sincerity under grievous suspicion. His *Letter from Rome, showing an exact Conformity between Popery and Paganism* (1729), was a severe attack on the Catholic ritual. He next assailed the orthodox champion Waterland, and startled the devout by giving up literal inspiration and the historical truth of the Old Testament stories. In 1747 and the following year he published his famous *Introductory Discourse* and the *Free Inquiry* into the miraculous powers claimed for the Christian church after the apostolic age. He attacked the ecclesiastical miracles, pointing out that their true source was in the general intellectual condition of the age that produced them, without needing to postulate either supernatural interference or human imposture. Middleton's best-known book is his well-written and enlogistic *Life of Cicero* (1741). See Sir Leslie Stephen's *English Thought in the Eighteenth Century*; also the article BELLENDEN (WILLIAM).

Middleton, JOHN, 1ST EARL OF MIDDLETON, born, probably in 1619, of a noble Scottish family, served with a regiment in France, then in the English parliamentary army, and became prominent in the army of the Covenant in Scotland, distinguishing himself at Philiphaugh (1645). He was one of the leaders of the Scottish army which invaded England in 1648 to deliver the king from the Independents, and was taken prisoner after a stern fight at Preston. Thereafter a royalist, he attempted several risings in Scotland, and was again taken prisoner at Worcester. He fled to the Continent, and returned as Earl of Middleton with Charles II. in 1660. Commissioner to the Scottish

parliaments of 1661 and 1662, he overreached himself in his endeavours to restore Episcopacy in Scotland, quarrelled with Lauderdale, and lost his offices in 1663. Later becoming governor of Tangier, he died there in 1673.

Middleton, RICHARD, poet and essayist, born in 1882, committed suicide in Brussels in 1911. Two series of *Poems and Songs* appeared in 1912-13, besides essays and short stories. See Savage, *Richard Middleton: The Man and his Works* (1922).

Middleton, THOMAS, dramatist, born about 1570, was the only son of William Middleton, gentleman, who settled in London and married Anne, daughter of William Snow. The earliest mention of Middleton in Henslowe's *Diary* is under date 22d May 1602, when he was engaged with Munday, Drayton, Webster, and others on a lost play, *Cæsar's Fall*. First on the list of his printed plays is *Blurt, Master Constable* (1602), a light, fanciful comedy. Two interesting tracts, *Father Hubbard's Tale* and *The Black Book*, exposing the practices of London rogues and sharpers, were published in 1604, to which year belongs the first part of *The Honest Whore* (mainly written by Dekker, but containing occasional scenes by Middleton). *The Phoenix* and *Michaelmas Term* (both published in 1607) are lively comedies; and even more diverting is *A Trick to Catch the Old One* (1608). *The Family of Love* (1608) and *Your Five Gallants*, n.d. [1608], are of slender merit; but *A Mad World, my Masters*, from which Aphra Behn pilfered freely in *The City Heiress*, is conducted with singular adroitness. All these early comedies of Middleton, even the poorest of them, are distinguished by smartness and buoyancy. *The Roaring Girl* (1611), written in conjunction with Dekker, describes the exploits of Mary Frith, a noted cut-purse and virago, who is turned into an attractive heroine by the kindly playwrights. In 1613, and frequently in later years, Middleton was employed to write the Lord Mayor's pageant. The highly amusing but somewhat indecorous comedy, *A Chaste Maid in Cheapside*, printed in 1630, was probably produced in 1613; and to that year may belong *No Wit, No Help like a Woman's*, first printed in 1657. *A Fair Quarrel* (1617), written with William Rowley, presents in the person of Captain Ager a noble example of blameless magnanimity. *The World Tost at Tennis* (1620), to which Rowley contributed, is an ingenious, well-written masque, contrived with more elaborate care than was usually bestowed on such compositions. On 6th September 1620 Middleton was appointed to the office of City Chronologer. A MS. City Chronicle compiled by him was extant in the 18th century, but has since disappeared. *More Dissemblers besides Women* (circa 1622, probably written in conjunction with Rowley), is more elaborate and substantial than the early comedies.

The dates of *The Witch*, *The Mayor of Quinborough*, and *The Old Law* are difficult to fix. *The Witch*, first printed in 1770, is interesting from the resemblance that it offers in the incantation scenes to the similar scenes in *Macbeth*, which was (probably) written earlier. Some of the songs from Middleton's play were foisted into *Macbeth* by the players. *The Mayor of Quinborough* (first printed in 1661) was supposed by Dyce to be one of Middleton's earliest plays; but a passage in iv. 3 is certainly imitated from *The Tempest*. The tragic scenes contain some of Middleton's most powerful writing; the broadly comic scenes may be safely assigned to Rowley. The delightful comedy, *The Old Law*, first published in 1656 as the work of Massinger, Middleton, and Rowley, bears some indications of having been originally produced in 1599. Massinger did no more than

revise the play on its revival at the Salisbury Court Theatre; and there is more of Rowley in it than of Middleton.

In the three posthumously published plays, *The Changeling*, *The Spanish Gypsy*, and *Women beware Women*, Middleton's genius is seen at its highest. Rowley had a share in the first two and probably in the third. *The Changeling* (written circa 1623) has not the sustained tragic power of Webster's masterpieces, and is weighted with a cumbrous comic underplot (evidently managed by Rowley); but it contains one scene (the colloquy between De Flores and Beatrice after the murder of Alonzo) that for sheer intensity of passion finds no parallel outside Shakespeare's greatest tragedies. It was one of the first plays revived at the Restoration. *The Spanish Gypsy* (circa 1623), a rich romantic play, opens sombrely, leading us to expect a tragical issue, but ends cheerfully; the breezy Gypsy-scenes are doubtless by Rowley. *Women beware Women* has a blithe beginning, but closes in tragic gloom. As a whole it is even more powerful than *The Changeling*.

A very curious, interesting, and skilful play is *A Game at Chess*, which was acted for nine days continuously, with unbounded applause, in August 1624. The cause of its great popularity was that it gave expression to the general feeling of satisfaction at the failure of the negotiations for the Spanish marriage. Gondomar ('the Black Knight') was satirised with scathing severity; and the Archbishop of Spalatro ('the Fat Bishop') was rudely handled. After the performance had continued for nine days a strong protest from Gondomar caused the withdrawal of the play; and both author and actors were summoned to appear before the Privy-council. Middleton shifted out of the way.

The Widow, a comedy of uncertain date, was published in 1652 as the work of Jonson, Fletcher, and Middleton; but it is difficult to assign any part to Jonson, and Fletcher's share was slight. The scene in act iv. where Latrocinio disguises himself as an empiric and dispenses his nostrums seems rather to be imitated from Ben Jonson than written by him. *Anything for a Quiet Life*, printed in 1662 and written circa 1619, may have been revised by Shirley.

In 1626 Middleton composed the city pageant, *The Triumphs of Health and Prosperity*. On 4th July 1627 he was buried at Newington Butts. He had married in 1602 or 1603 Mary, daughter of Edward Morbeck, one of the six clerks in Chancery; and his son Edward, the only child of the marriage, was born in 1604. The widow survived for about a year. Ben Jonson succeeded to the post of City Chronologer.

Middleton was concerned in the authorship of some of the plays included in the works of Beaumont and Fletcher. Mr Fleay plausibly assigns to him *A Match at Midnight* (usually attributed to Rowley) and the pseudo-Shakespearean *Puritan*.

Dyce's edition of Middleton appeared in 1840 (5 vols.); A. H. Bullen in 1885-86 (8 vols.). Selected Plays, with an Introduction by Swinburne, are included in the 'Mermaid' Series, ed. Havelock Ellis.

Middletown. (1) a city and port of entry of Connecticut, on the right bank of the Connecticut River, 15 miles below Hartford, at the junction of three railway lines. It is a well-built town, dating from 1636, with wide, shaded streets and numerous handsome residences. Here are the Wesleyan University (1831), the Berkeley Divinity School (Episcopal), a large state hospital for the insane, and an industrial school for girls. The manufactures include pumps, textiles, hardware, &c. Pop. 14,000.—(2) A city of New York, 67 miles by rail NNW. of New York City. It contains

the state homœopathic insane asylum, and has manufactures of machinery, hats, &c. Pop. 18,400.—(3) A city of Ohio, on the Miami River and Canal, 28 miles N. of Cincinnati, with paper-mills and other factories. Pop. 23,600.

Middlewich, an old-fashioned market-town of Cheshire, on the river Dane and the Grand Trunk Canal, 21 miles E. of Chester. Its salt-manufacture dates from Saxon times at least. Pop. 5000.

Midgard. See SCANDINAVIAN MYTHOLOGY.

Midge, a common name for many different kinds of delicate flies, more or less gnat-like in structure, but usually harmless in habit. The adults dance in great swarms in the air; the larvæ are usually aquatic. A common little brown midge, *Corythra plumicornis*, has beautifully transparent larvæ, frequent in stagnant water; while those of *Chironomus plumosus* are bright red, known as blood-worms, and much sought after by birds and fishes. The name is sometimes extended beyond the limits of the family Chironomidæ to include such forms as the formidable Danubian gnat (*Simulium columbascense*) or the allied buffalo gnat of the southern United States. See GNAT.

Midhurst, a small town of Sussex, on the Rother, a navigable tributary of the Arun, 65 miles by rail SW. of London and 12 N. of Chichester. Cobden was born close by, and Lyell was educated at the grammar-school (1672). Cowdray House, $\frac{1}{2}$ mile NE., built about 1530 by Southampton, was in 1793 reduced by fire to a beautiful ruin. Till 1885 Midhurst borough (35 sq. m.) returned a member to parliament.

Midi, CANAL DU, DENT DU. See GARONNE, DENT DU MIDI.

Midianites, an Arab race, descended, according to Scripture, from Midian, the son of Abraham by Keturah. They occupied great part of the country between the Red Sea and the Plains of Moab, and had their headquarters east of what is now the Gulf of Akabah. They were at least partly nomadic, but their caravans brought gold and incense from the south to Palestine, and traded between Egypt and Syria. Some of them lived near Sinai; to them belonged Jethro, priest or sheik of Midian—the father-in-law of Moses. The Midianites were very troublesome neighbours to the Israelites till Gideon's victory over them. The national god was Baal-Peor. In Midian proper, to the east and south-east of the Gulf of Akabah, the Romans had valuable mines. Sir Richard Burton was convinced that gold was still to be found there, and as an outcome of visits paid in this interest wrote his *Gold Mines and Ruined Cities of Midian* (1878), and *Midian Revisited* (1879). Later travellers have not confirmed his opinion; but petroleum seems to occur. Midian ceased to be Egyptian and became Turkish again in 1887. Turkish rule ended with the Great War. The political conditions in Arabia at the present day are unstable and many of the neighbouring tribes are affected, so that it is difficult to forecast the immediate future and to guess to which of the four states—Egypt, Palestine, Trans-Jordania, or Arabia—the modern descendants of the ancient Midianites either do or will own allegiance. The biblical references to Midian are critically discussed in the *Cambridge Ancient History* (vol. ii.). See also articles in *Jew. Ency.* and *Ency. Brit.* For the general relations of Jews and Arabs, see Prof. D. S. Margoliouth (Schweich Lectures for 1921, publ. Oxford, 1924). The works of modern travellers should also be consulted, e.g. W. E. Palgrave, *Narrative of a Year's Journey* (Lond. 1868); C. M. Doughty, *Travels in Arabia* (Lond. 1921), *Wanderings in*

Arabia (Lond. 1923); and H. St John B. Philby, *The Heart of Arabia* (Lond. 1922).

Midlothian. See EDINBURGHSIRE, ROSEBERRY.

Midnapur, capital of a district in Bengal, on the Kasai River, 63 miles W. of Calcutta by road and canal. There are some manufactures, and an American mission to the Santals. Pop. 29,000.

Midrash, the Hebrew exposition of the Old Testament. See EXEGESIS.

Midriff. See DIAPHRAGM.

Midshipman, the title under which formerly young officers entered the British navy. From song and story, and especially from Marryat's novels, 'the midshipmite' has acquired a historic interest, and become inseparably associated with the navy. The term is derived from the fact that in the old British men-of-war the 'young gentlemen' had their quarters *amidships* on the lower deck. The United States, whose navy borrowed the term from Britain, abolished it by act of congress in 1882, but revived it in 1902. Great changes have taken place in the method of entry of junior officers in the British navy. These new regulations involved the final disappearance from the service of the sailing training-vessels, and the fact that 'training in masts and yards and sails has disappeared never to return.' See NAVY.

Midsummer Day—24th June—is one of the four English quarter-days. For Midsummer Eve, see JOHN'S (EVE OF ST.).

Midwifery. The Midwives Act of 1902 provides that after 1st April 1905 any woman, not being certified under this act, who shall use the name and title of midwife in England shall be liable, on conviction, to a fine not exceeding £5; that after 1st April 1910 no woman shall for gain attend women in childbirth except under the direction of a qualified medical practitioner, unless certified under this act, the penalty being a fine not exceeding £10. The act, however, does not apply to legally qualified medical practitioners, or to any one rendering assistance in cases of emergency. The Midwives (Scotland) Act of 1915 made like provision for Scotland from 1st January 1917 and 1st January 1922 respectively. See OBSTETRICS.

Mieris, FRANS VAN, Dutch painter, born at Leyden, 16th April 1635, died there, 12th March 1681. He painted genre pictures and portraits, all of small size. He was a pupil of Gerard Dow, but, though a very able painter, scarcely rises to the level of his master. His son, Willem (1662-1747), and Willem's son, Frans (1689-1763), followed closely in his footsteps.

Miescher's Vesicles. See GREGARINIDA.

Mignard, PIERRE (1612-95), French artist, trained with Vouet at Paris, but soon went to Rome, where he won for himself no small reputation as a painter of portraits and frescoes. Migrating in 1658 to the court of Louis XIV., he employed himself painting portraits of all the great personages of the society of the day—Maintenon, Sévigné, Turenne, Molière, Bossuet, &c. The king sat to him ten times. Amongst other buildings he decorated the cupola of the Val de Grâce, a most elaborate piece of work, while he also produced numerous religious pictures. After a lengthy quarrel with Le Brun, the president of the Academy, he succeeded him in office in 1690. He intended to decorate the cupola of the Invalides, but he was already over eighty, and death cut short his project.

Migne, JACQUES PAUL, to whom Catholic theology owes a great debt of gratitude, was born at St Flour in Cantal, 25th October 1800, and died in Paris on his seventy-fifth birthday. He was educated at the seminary at Orleans, was ordained priest in 1824, and served some time as

curate at Puisieux in the diocese of Orleans. A difference with his bishop about a book on the liberty of the priests drove him to Paris in 1833, where he started *L'Univers Religieux*, afterwards called simply *L'Univers*. In 1836 he sold the paper, and soon after set up a great publishing house at Petit Montrouge, near Paris, which gave to the world, besides numerous other works of theology, *Scriptura sacrae cursus completus* and *Theologie cursus* (each 28 vols. 1840-45), *Collection des Orateurs sacrés* (100 vols. 1846-48), *Patrologia cursus completus* (Latin series, 221 vols., 1844 *et seq.*; 2d ed. 1878 *et seq.*; 1st Greek series, 104 vols., 2d series, 58 vols., both since 1857), and the *Encyclopédie théologique* (171 vols. 1844-66). Unfortunately these editions were prepared too hastily, and moreover by superficial scholars, so that they do not possess critical value. The Archbishop of Paris, thinking that the Abbé Migne's great undertaking had become a mere commercial speculation, forbade it to be continued, and, when the indefatigable director refused to obey, suspended him. A great fire, more powerful than the veto of the archbishop, put an end to the work in February 1868.

Mignet, FRANÇOIS AUGUSTE MARIE, a great French historian, was born 8th May 1796 at Aix in Provence, studied at Avignon, and then law at Aix. His true vocation was at once apparent in the no less solid than brilliant prize-essay for the Academy of Inscriptions on the institutions of France in the time of St Louis. In 1821 he went to Paris, and soon began to write for the *Courrier Français*, and to lecture with applause on Modern History at the Athénée. In the spring of 1824 appeared his *Histoire de la Révolution Française*, a sane and admirable summary—the first complete history by one other than an actor in the great drama. Mignet joined the staff of the *National*, and with Thiers signed the famous protest of the journalists on 25th July 1830. After the revolution of 1830 he became Keeper of the Archives at the Foreign Office, but lost this in 1848. In 1833 he went on a confidential mission to Spain, and used the opportunity to explore the famous Simancas Archives. Elected to the Academy of Moral Sciences at its foundation in 1832, he succeeded Comte as its perpetual secretary in 1837, and was elected to fill Raynouard's chair among the Forty in 1836. He died 24th March 1884. Mignet was the first great specialist in French history who devoted himself to the complete study of particular periods, and in his work he displayed a marvellous mastery of documents.

Mignonette (*Reseda odorata*), a plant of the natural order Resedaceæ, a native of Cyrenaica, in universal cultivation on account of the delicious fragrance of its flowers. Though usually cultivated as an annual, it is really a perennial, and assumes a sub-shrubby character when protected from cold and wet in winter. It was first introduced into England by Lord Bateman, who brought it from the Royal Garden at Paris in 1752; nor had it then been long known in France. It rapidly became a universal favourite throughout Europe. The French name *mignonette*, now its popular name everywhere, signifies *Little Darling*. In French the name *mignonette* is applied to many flowers, to this among others, but its usual name is *réséda*. What is called *Tree Mignonette* is not even a distinct variety, but merely the common kind trained in an erect form, and prevented from early flowering by pinching off the ends of the shoots. The name *Mignonette tree*, however, or *Jamaica mignonette*, is sometimes given to *Lawsonia inermis*, or Henna

(q.v.), of the order Lythraceæ.—Weld (q.v.) belongs to the same genus as *mignonette*.—Another British species is *Reseda lutea*, or wild mignonette, a smaller plant than weld, also found in waste places. It has commonly six sepals and six petals, the two upper petals having three lobes, the two lateral petals two, and the two lower being undivided.

Migraine (Fr., from Lat. *hemisphæra*, Gr. *hēmi*, 'half,' *kranion*, 'skull;') the same word as *megrin*, a severe headache usually affecting only one side of the head. See HEADACHE.

Migration is generally understood to mean the movement of a people as a whole, and is distinguished from Emigration (q.v.) and Immigration (q.v.), in which only individuals and families participate, from Colonisation, in which the surplus population swarms off (see COLONY), and from mere military invasion. Some possible early migrations of the Indo-Germanic peoples are discussed in the article ARYANS and ARYAN LANGUAGES. A later series of movements called the *Völkerwanderung* occurred among the German tribes. The movements of the Huns and Avars, their pressure upon the Germans, the wanderings of the Goths and other Germanic nations, their strife among themselves and with the Roman Empire, are dealt with in the articles HUNS, AVARS, GOTHs, BURGUNDY, VANDALS, ALBEMANNI, GEPIDÆ, LOMBARDS, FRANKS. For the peopling of England and Lowland Scotland see ANGLES, JUTES, SAXONS, and ENGLAND (*History*); and for the last stages in the Germanic *Völkerwanderung* see the article NORTHMEN and the references there. For other peoples see SLAVS, HUNGARY (*History*; for the Magyars), and similar articles.

Migration, a term applied rather loosely to more or less periodic mass-movements of animals, notably birds, from one place to another. Thus many naturalists speak of the migration of locusts, of herring, of eels, of lemmings, though the mass-movements of these animals are very different in character from the typical migrations of birds. The central facts in regard to migration in the strict sense are that it recurs with regular periodicity, that it takes place between one seasonal habitat and another, that there is always a return journey, and that it has a twofold reference, partly to changes in meteorological conditions and food-supply, partly to the continuance of the race and the requirements of the young. Thus in birds there is a seasonal oscillation between the summer-quarters, the breeding and nesting-place, in the colder part of the range, and the winter-quarters, the feeding and resting-place, in the warmer part of the range. In a north temperate country, like Britain, the majority of the birds are migratory, a small minority are residents, such as red grouse and sparrow. The migrants may be distinguished as follows: (a) There are *summer visitors*, arriving from the south in spring and early summer, breeding in the country, and leaving again for their southern winter-quarters in late summer or autumn. Swallow and swift, cuckoo and nightingale, corn-crake and puffin, are familiar examples. (b) There are *winter visitors*, such as fieldfare and redwing, snow-bunting and great northern diver, which come from the north in autumn, remain throughout the winter, and return in early spring to their northern breeding haunts. (c) There are the *birds of passage* in the stricter sense, such as some sandpipers, which spend a short time twice a year in the country in question on their way farther north or farther south. (d) There are the *partial migrants*, such as lapwing and goldfinch, which shift their quarters from one part of the country to another, or which include many representatives that leave

the country and many that stay. It is plain that birds which seem to be resident in a particular area, since there is no month in the year when they are unrepresented, may be, in point of fact, partial migrants. One set may go southwards, for instance, and their place may be taken by another set from farther north. Careful investigations have shown that this is common. It is also plain that a winter visitor in one country will be a summer visitor farther north, and that a 'bird of passage' in one country will be a summer visitor or a winter visitor in another country.

The migratory movements differ greatly in range. In warm countries there may be little more than an oscillation between the uplands and the valleys. Many British curlews frequent the shore-areas in the cold part of the year and the high moors in their breeding season. Arctic terns, on the other hand, have been seen within the Antarctic Circle, and the Pacific golden plover flies from the Hawaii Islands to Alaska to breed. Whatever be the distance travelled, the general rule is that birds breed in the colder part of their migratory range. There is in many cases a twofold regularity in the migratory movement as regards time and as regards space; this points to the fact that the migration is old-established, and that it has come to work with great smoothness. As regards time, there is often a striking uniformity in the dates of arrival in a given area, and a less marked uniformity in the dates of departure. As regards space, it has been proved by marking birds that, in some cases, e.g., stork and swallow, an individual may return from a winter sojourn in the south to the building where it was hatched, or where it made its nest, the year before. For certain birds there seems to be considerable regularity in the migratory routes, but precise knowledge is still scanty. There is often a tendency to follow a coast-line, a chain of islands, a river-valley, and so on; and in some cases, e.g., that of the Pacific golden plover, there is evidence of a gradual short-cutting of the paths followed. In a north temperate country the prevalent direction of the autumnal movement of the summer visitors is from north to south, from north to south-east, from east to west and then south. The immigration of the summer visitors into a north temperate country is mainly from south to north, or from south to north with a divergence eastward and westward. By marking birds with numbered rings, some secure data as to migratory routes are being gradually accumulated; thus it is certain that many North-European storks pass southwards in autumn through Africa to Natal and similar areas. There is sometimes a marked difference between the spring flight northwards, which tends to be impetuous, with few or no interruptions, and by the shortest route, and the autumn flight southwards, which tends to be more leisurely and dallying and more circuitous. The first migrants to arrive in a north temperate country in spring are the mature birds, the males often leading; the immature birds bring up the rear. In autumn, however, the order is reversed; the older birds linger longer, the younger birds leave first, with the exception of the European cuckoo, where the parents may leave a month or so before their offspring. Some migrants, such as larks, starlings, thrushes, and hooded crows fly rather low; the majority fly high; and some pursue their way at a great height—of 1000–3000 feet. Many migrants continue their journey by night. Estimates of the velocity of the migratory flight are often exaggerated, but some birds attain to fifty miles an hour.

The impulse to migrate at particular times, and the capacity of migrating, seem to be inborn or instinctive, engrained in the race in the course of

ages. The impulse is exhibited by young birds who have known no winter, and by caged birds physically comfortable; it often asserts itself before there is any pinch of external circumstances; it occurs at many different levels of intelligence among other backboned animals, such as salmon, turtle, and seal. Its history is probably wrapped up, like that of many racial peculiarities in mankind, with the history of changing climates. Not that the climatic changes can be thought of as directly engendering a migratory habit, but rather that variations of the nature of periodic restlessness, like 'roving' in mankind, would have survival-value in certain conditions, and tend to become racial characteristics. Long, cold, dark, and sterile winters would favour the survival of restless experimenting birds which began migrating southwards; they would make for the elimination of the dull, the sluggish, the foolhardy, and the inept. Another factor would be the overcrowding at the end of the breeding season. The return journey in spring from the winter-quarters, say in a semi-tropical country, to the colder breeding area, may be associated with the risks and discomforts of nesting in hot and dry places, and also with the abundance of food (insects, fruits, and seeds) characteristic of summer in many northern areas. It is not inconsistent, with this view of the migratory impulse and capacity, to look for internal and external conditions which serve as trigger-pulling stimuli, or to look for facts which may throw light on the way-finding.

While there is considerable mortality in the yearly migrations of birds, especially when the weather is unpropitious, the striking fact is that a large measure of success usually attends the adventure. This way-finding remains an unsolved problem. Allowance may be made for the utilisation of land-marks; but these are not available at night, nor across the pathless sea. Allowance may be made for some measure of social tradition, those birds that followed well one year may lead well the next; but, in the case of most British birds, the novices are said to go off first, apparently unattended by old experienced hands. As it is difficult to be confident in regard to statements of this sort, the further difficulty in the way of the tradition theory may be noted that it is not possible to indicate what the physiological or psychological content of the tradition would be in the case of birds migrating in the darkness, at a great height, and across an expanse of sea. Very important experiments by Watson and Lashley have shown, for instance, that nesting terns from the Tortugas, at the mouth of the Gulf of Florida, may be transported by steamer, in hooded cages, over unknown waters to the north and west, for 800 miles or more, and yet find their way back in a short time in a varying percentage of cases. A provisional eclectic statement may be suggested, that birds utilise stimuli, at present undetected, which have hereditarily come to have directive significance; that the impulse and constitutional capacity represent the outcome of ages of selection operating on favourable germinal variations; and that something may be allowed for individual acuteness and for socialised co-operation.

The march of Lemmings (q.v.) is not a true migration; it is an attempt to deal with irregularly recurrent over-population, and there is no return journey. The same may be said in regard to the invasions of Locusts (q.v.). The mass-movements of some gregarious fishes—like mackerel and herring—imply (1) a pursuit of the crustaceans and the like which form the staple food, and which vary in abundance according to the seasons and local conditions; and (2) a working along tracts of congenial temperature, salinity, oxygenation, and

the like; but they are not migrations in the strict sense. Apart from birds, true migrations are illustrated by some fishes, such as salmon and sturgeon (and also by eels, though there is no return journey of the adults after spawning); by some marine turtles among reptiles; by seals, some whales, and some bats among mammals.

Newton, article 'Migration' in *Dictionary of Birds* (1893-96); Gätke, *Heligoland as an Ornithological Observatory* (1895); W. P. Pycraft, *History of Birds* (1910); J. B. Watson and K. S. Lashley, *Observations on Nesting Terns at the Tortugas* (Carnegie Institution, Washington, vii. 1915); J. Arthur Thomson, *The Biology of the Seasons* (1911), *The Wonder of Life* (1914), *Secrets of Animal Life* (1919), *The Biology of Birds* (1923).

Miguel, MARIA EVARIST, usurper of the throne of Portugal, was born at Lisbon, 26th October 1802, the third son of King John VI. A determined hater of all constitutional principles, he plotted (1824) to overthrow the constitutional form of government granted by his father: he caused the ministers to be arrested and his father to be closely watched in his palace; but the aged king escaped to an English man-of-war anchored in the estuary. Miguel and his mother, his principal abettor, were banished. At the death of John VI. in 1826 the throne devolved upon Miguel's elder brother, Pedro, the emperor of Brazil; he, however, resigned it in favour of his daughter, Maria, but making Miguel regent till her majority. Miguel at once dissolved the constitutional cortes, summoned the cortes that had preceded it, and was on 30th June 1828 by it proclaimed king. But Pedro (who had abdicated in 1831) gathered an army at the Azores, and in 1832 captured Oporto and Lisbon, and Charles Napier destroyed Miguel's fleet off Cape St Vincent (1833). Next year Maria was restored to the throne, and Miguel withdrew to Italy, protesting. He died on 14th November 1866 at Bronnbach, near Wertheim in Baden, having been a spoilt youth, a wildly dissolute man, and a tyrannical ruler.

Miklosich, FRANZ VON, the greatest of Slavonic scholars, was born at Luttenberg, in the Slovenian part of Styria, 20th November 1813. After studying law at Graz University he went in 1838 to Vienna to practise as an advocate, but was led by Kopitar to the study of philology, and in 1844 obtained a post in the Imperial Library. From 1850 to 1885 he was professor of Slavonic at Vienna, in 1851 being elected to the Academy, and knighted in 1869. He died 7th March 1891. His works, nearly thirty in number, include *Radices Linguae Palaeoslovenicae* (1845); *Lexicon Linguae Palaeoslovenicae* (1850); *Vergleichende Grammatik der Slawischen Sprachen* (4 vols. 1852-74), which did for Slavonic what Grimm and Diez did for the German and the Romance languages; *Die Bildung der Slawischen Personennamen* (1860); *Ueber die Mundarten und die Wanderungen der Zigeuner Europas* (12 parts, 1872-80); *Rumänische Untersuchungen* (1882); and *Etymologisches Wörterbuch der Slawischen Sprachen* (1886).

Miknas, MEQUINEZ, or MIKNASA, a town of Morocco, 32 miles W. by S. of Fez and 70 miles from the coast, stands amidst olive groves on the slope of a hill. It is surrounded by walls, and is perhaps the best built town in Morocco. The palace is the summer residence of the sultan, and the mosque of Muley Ismail is the burial-place of the royal house. Pop. about 30,000. For the place and its history, see works named at MOROCCO.

Mikulov. See NIKOLSBURG.

Milan, the second in size of Italian cities, stands in the great plain of Lombardy, 80 miles N.E. of Turin, 155 W. of Venice, and 25 S. of the Lake of Como at the foot of the Alps. The city, nearly circular in shape, is surrounded on three sides by walls, has a circuit of nearly 8 miles, and is entered by 14 gates. Although a place of great antiquity, it does not possess many very old buildings: it has been too greatly ravaged by war. The modern city is a busy, enterprising, and wealthy community. The streets are broad and regular, and the houses substantial and roomy. The principal church is the cathedral of the archbishop, the foundation of which was laid, on a site where already two cathedrals had stood, by Gian Galeazzo Visconti in 1386; it was completed by order of Napoleon I. in 1805-13. It is built entirely of marble, and in the Gothic style, with an approach to Flamboyant in the ornamentation; but the windows and portals of the façade (16th century) are Italian. The

(given by the king to the nation in 1919), with fine modern frescoes; the Late Renaissance municipal palace (1558); the Poldi-Pezzoli palace, with a collection of paintings of Leonardo da Vinci's school, armour, and artistic objects; and several others. In 1900 the municipal art and archaeological museums were transferred to the restored Castello Sforzesco. The arcaded colonnade of Victor Emmanuel (1865-67), lined with fine shops, forms a favourite promenade of the people. The Arch of Peace, built of white marble (1807-38), commemorates the exploits of Napoleon. The Della Scala opera-house (1778) is the second largest (next after San Carlo at Naples) in Italy. Beccaria, Manzoni, the popes Pius IV. and Gregory XIV. were natives of Milan. A university was opened in 1924. The principal other scientific and artistic institutions are an academy, a higher technical institute, several scientific societies, a museum of natural history, schools of veterinary practice, music, and a military geographical institute. The charitable institutions are numerous and splendidly endowed; the Great Hospital (founded in 1448) can accommodate 2500 patients. Owing to its central situation in the upper valley of the Po, to the fact that it is the principal meeting-place of the north Italian railways and canals, and owing to its proximity to the Alpine passes, Milan has always been a place of much commerce. It now carries on a vast trade, much increased since the opening of the Gothard railway, in raw silk, cotton, grain, rice, and cheese, and manufactures silks, velvets, gold, silver, and iron wares, railway carriages, tobacco, porcelain, electric-light apparatus, and is an active centre of the printing-trade. Milan is the chief financial and banking city of North Italy. Pop.

Milan Cathedral.

exterior is adorned with some 2000 statues in niches and a vast number of pinnacles. Other noticeable churches are St Ambrose, founded in 868, on the site of one dedicated by the saint himself in 387—it has early mosaics, an altar with clever goldsmith's work, and other antiquities; St Eustorgius, dedicated in 320, with interesting sepulchral monuments; St George, founded in 750 but greatly modernised, with pictures by Luini and Ferrari; St Maria delle Grazie (built 1463), on the walls of whose refectory is Leonardo da Vinci's 'Last Supper'; and St Maurice the Greater (1497-1506), adorned with paintings by Luini and his school. The principal secular building is the Brera Palace (12th century), formerly a Jesuit college, now the palace of arts and sciences, which shelters within its precincts a very valuable gallery of paintings by such masters as Raphael, Da Vinci, Luini, Mantegna, the Bellinis, Titian, Vandyck, &c., an academy of art, a collection of casts for modelling, the magnificent monument of Gaston de Foix, the national library (1770), archaeological museum, and observatory. In the famous Ambrosian Library (1609) there are collections of drawings, engravings, and pictures. The city is adorned with numerous palaces, as that of the archbishop (1570); the royal palace

(1911) 599,200; (1921) 718,800.

Milan (Lat. *Mediolanum*) was originally a town of the Insubrian Gauls. It was conquered by the Romans, 222 B.C., and under them became a conspicuous centre of wealth and civic influence; its citizens were noted for their refined manners and literary tastes, and the public buildings for their beauty and elegance. In the beginning of the 4th century it was selected as the residence of the imperial court by Maximian. It was sacked by the Huns (under Attila) in 452, by the Goths in 539, and passed to the Longobards (569), and to the Franks previous to its subjection by the German empire. Here several of the German emperors were crowned with the Iron Crown. The city was in the 11th century the head of the Lombard League of towns that opposed Frederick I., who twice besieged it, and once razed it to the ground. Nevertheless it continued to prosper, notwithstanding that it was distracted by the intestine feuds of the Guelphs and Ghibellines. Supreme power became eventually (from 1277) vested in the Ghibelline Visconti, who extended the ascendancy of Milan over the whole of Lombardy, and in 1395 bought from the emperor the title of duke. The successors of the Visconti in the lordship of Milan were the Sforzas (1450-1535). From 1555 to 1713

Milan submitted to the predominance of Spain, and from Spain passed to Austria. Under Bonaparte it was declared the capital of the Cisalpine Republic, of the Italian Republic, and, finally, of the kingdom of Italy. In 1815 Milan was restored to Austria, and continued the capital of the Lombardo-Venetian kingdom until the annexation of Lombardy to Piedmont in 1859 by the peace of Villafranca.—The province has an area of 1220 sq. m. and a pop. (1921) of over 1,900,000. See Histories by Rosmini (1820), Canù (1844), Cusani (1862-67), Bonfadini (1890), Holtzmann (1899), and Dorothy Muir (1924); also E. Hutton, *Milan and Lombardy* (1925). For the Milan Decrees, see CONTINENTAL SYSTEM.

Milazzo (anc. *Mylæ*), a fortified seaport of Sicily, on a promontory 21 miles W. of Messina. Off *Mylæ* in 260 B.C. the Romans won a great sea-fight over the Carthaginians; and here on 20th July 1860 Garibaldi, with 2500 men, defeated 7000 Neapolitans. Pop. 20,000.

Mildew (O. E. *meledæaw*, 'honey-dew,' confused with *meal*), a general name applied to numerous diseases of plants caused by or associated with the parasitism of certain fungi. Some of the most important are species of *Erysiphe*, and are common both on leaves and green stems of many Dicotyledons and a few Monocotyledons. The filaments of the fungus branch and spread over the epidermis of the plant, sending suckers every here and there into the cells. They multiply by the asexual formation of spores, and in most cases also from sexually produced fructifications. Among the common forms may be noted: *Erysiphe lamprocarpa* on Compositæ, Plantago, Verbascum, Labiatae; *E. graminis* on grasses; *E. Martii* on Umbelliferae and Leguminosæ; *E. communis* on Polygonum, Rumex, Convolvulus, Teasel, Ranunculus, &c.; *Oidium Tuckeri* on the vine; *Podosphaera Kunzei* on Prunus; *P. castagnei* on hops. These are all nearly related, but the mildew or rust of corn (*Puccinia graminis* or *Æcidium berberidis*), whose life is divided between barley and cereal, belongs to a distinct series. See FUNGI.

Mildura, an irrigation district on the Murray River, in the north-west of Victoria. Thanks to the success of irrigation, Mildura has rapidly become one of the chief fruit-growing centres in Australia. It produces oranges, lemons, grapes, also some wheat. Population of town, 5500.

Mile, a terrestrial measure of length, is derived from the Roman *milliare*, which contained 1000 paces (*mille passuum*) of 5 Roman feet each, the pace being the length of the two steps made by a pair of feet. The Roman foot being between 11·65 and 11·62 English inches, the Roman mile was thus less than the present English mile by from 142 to 144 yards. The length of the modern mile in different countries exhibits a remarkable diversity not satisfactorily accounted for. Before the time of Elizabeth, scientific writers made use of a mile of 5000 English feet, from the notion that this was the Roman mile, forgetting the difference in value between the English and Roman foot. The present statute mile was incidentally defined by an act passed in the thirty-fifth year of the reign of Elizabeth to be '8 furlongs of 40 perches of 16½ feet each'—i.e. 1760 yards of 3 feet each; and it has since retained this value. The *geographical* or *nautical mile* (see KNOT) is the sixtieth part of a degree of the equator (= 1·151 English statute mile), and is employed by the mariners of all nations; but in Germany the geographical mile denotes $\frac{1}{15}$ th part of a degree in the equator, or 4 nautical miles.

Milesians, another name for the Scots, the last of the prehistoric invaders of Ireland (q.v.);

from an assumed eponymous ancestor *Milesius*, whose name is a modification of *Miles*, a Latin translation of the Celtic *Gulam*. See also MILETUS.

Miletus, anciently the most flourishing city of Ionia, in Asia Minor, situated near the mouth of the Mæander, was famous for its woollen cloth and carpets, and its furniture, and for its extensive trade. Before being forcibly colonised by the Ionians (see IONIA) under Neleus, it appears to have been inhabited by Carians or by Leleges. Its people early founded nearly fourscore colonies on the Black Sea and in the Crimea—Abydos, Lamp-sacus, Cyzicus, Sinope, Amisus, Olbia, Panticapæum, &c.—sent merchant fleets to every part of the Mediterranean, and even into the Atlantic, and maintained an obstinate war with the early Lydian kings, until Croesus was at length acknowledged as their master. They were believed to be the purest representatives of the Ionians in Asia. After the conquest of Lydia by the elder Cyrus, Miletus submitted to Persia; but in 500 B.C. it was stirred up to rebellion against the Persians. Six years later Darius besieged the city, stormed it, plundered it, massacred most of its inhabitants, and banished the survivors to the mouth of the Tigris. Afterwards it was rebuilt, but never regained its former importance, although its people frustrated the attempt of the Athenians to compel their allegiance, and dared to resist Alexander till he stormed the city. It was a second-rate commercial town down to the time of Pliny, and was finally ruined by the Turks. Miletus was the birthplace of the philosophers Thales, Anaximander, and Anaximenes, and of the historians Cadmus and Hecataeus. See a history by Miss Dunham (1915).—Short tales, mostly in dialogue, and of a witty and obscene character, were greatly in vogue amongst the Greeks under the name of 'Milesian tales.'

Milfoil, a name applied to several kinds of plants as the Common Milfoil or Yarrow (*Achillea Millefolium*), the Hooded Milfoil (*Utricularia*), and the Water Milfoil (*Myriophyllum*). The first-named is invariably understood by the term when it is used without any qualifying adjective. The plant belongs to the Compositæ. It is one of the commonest of British plants, and is very abundant in Europe and Russian Asia, from the Mediterranean to the Arctic Circle, and extends over a great part of North America. The plant is medicinal, being mildly aromatic, tonic, and stimulant; and yields tannin, a bitter extractive, a volatile oil, and an acid called *achilleic acid*.

Milford, a town of Massachusetts, 36 miles W. by S. of Boston, with manufactures of boots and shoes, straw goods, and machinery; pop. 13,500.

Milford Haven, a seaport of South Wales, in the county of Pembroke, till 1918 a parliamentary borough of the Pembroke group, is pleasantly situated on the north side of Milford Haven, about 7 miles ENE. of St Ann's Head, and (by rail) 27½ miles W. of London. The town itself presents few features of interest; the Haven, which as a natural harbour is unequalled in area, complete shelter, and facility of entrance, being by far the greater attraction. Stretching inland some 10 miles, it varies in breadth from 1 to nearly 2 miles, and has a depth in most places of from 15 to 19 fathoms—even at low-water spring-tides there being a minimum depth of 8 fathoms. In 1485 the Earl of Richmond (afterwards Henry VII.) disembarked here from Brittany shortly before the battle of Bosworth. The history of the town proper is relatively short but varied. At present it is of considerable importance as the headquarters of a fleet of steam-trawlers, while fish-curing is largely carried on. New docks were

constructed towards the close of last century, but the trade of the port has not developed much, although proposals have been made from time to time to make it a terminus of transatlantic trade. Pop. 6400.

Milford Haven, MARQUESS OF. See **BATTENBERG**.

Military Law. See **MARTIAL LAW, COURT-MARTIAL, and MUTINY.**

Military Orders, religious associations whose members united in themselves the double characters of monk and knight. These orders arose about the period of the Crusades, the first to be formed being the Hospitallers (q.v.). Their primary duties were to tend sick pilgrims at Jerusalem, afterwards to protect them also on their way to the holy city. The order of the Templars (q.v.) soon followed; their purpose was to protect pilgrims, a duty to which was afterwards added that of guarding the Temple at Jerusalem. The orders of Alcántara, of Calatrava, and of Santiago of the Sword, in Spain, had for their immediate object the defence of their country and creed against the Moors. These orders, as well as that of St Bennet of Aviz in Portugal, which was instituted with a similar view, differed from the Templars and the Knights of St John (Hospitallers) in that their members were permitted to marry. The same privilege was enjoyed in the Savoyard order of Knights of St Maurice and the Bavarian order of St Hubert. On the contrary, the Teutonic Knights (q.v.), who had their origin in the Crusades, but afterwards made the south-east and east shores of the Baltic the theatre of their activity, were bound by an absolute vow of chastity. These religious associations have mostly been abolished or have fallen into disuse, though some still subsist as orders of knighthood.

Military Schools in connection with the British army are of three classes. First, the Royal Military School (Duke of York's) now at Dover, the Queen Victoria School at Dunblane, and the Royal Hibernian Military School at Shorncliffe, Kent, where the sons of soldiers receive a general education free of charge. Preference is given to orphans and to those whose parents are in straitened circumstances or have rendered meritorious service. Candidates must be likely to become fit for military life, and though there is no compulsion to enter the army on leaving the majority do so. The commandants of these establishments are officers of the army, and the indoor teaching is conducted by members of the Army Educational Corps. The Duke of York's School was founded in 1801; the Queen Victoria School, founded in 1905 as a memorial to the Scottish soldiers and sailors who fell in the South African war, was opened in 1909, and also admits the sons of sailors. To this class belonged also the Royal Hibernian School at Dublin, afterwards at Shorncliffe. It originated from the Hibernian Society of 1765, and was abolished in 1924. The second class comprises the Royal Military Academy, Woolwich, the Royal Military College, Sandhurst, and the Royal Army Medical College at Millbank, where cadets qualify for commissions under special instruction. The third class includes those establishments where officers, non-commissioned officers, or men, already in the service, receive technical instruction in various branches of military art—the Staff College at Camberley, the War Office School of Education at Shorncliffe, the School of Gunnery at Shoeburyness (the Artillery College), the School of Musketry at Hythe, the Army Veterinary School, the Royal Military School of Music at Kneller Hall, Hounslow, and many others. All are under officers of the army,

and, with very few exceptions, the instructors are also officers or sergeants. The Royal Military Academy at Woolwich is described at **ARTILLERY**.

The Royal Military College at Sandhurst, in Berkshire, 33 miles WSW. of London, was organised in 1858. Admission to Sandhurst is obtained by open competition at examinations. Successful candidates remain there normally for eighteen months, and, subject to passing the half-yearly examinations in various subjects, are then given commissions as second-lieutenants. At the Royal Army Medical College in London (superseding the Netley school) medical candidates already professionally qualified are given further instruction. Professors and assistant professors are mostly officers in the Royal Army Medical Corps. After examination the candidates are commissioned as surgeons in the army. Entrance to the Staff College at Camberley, near Sandhurst, is obtained by competitive examination. A service of at least five years is also required, and candidates must be under thirty-seven years of age, be captains or have passed the qualifying examination for that rank, and have been selected by their commanding officers as fit for the staff in physical qualifications, military knowledge, conduct, habits, and temper. At the School of Gunnery, Shoeburyness, officers and men of the Royal Artillery undergo a course of gunnery and artillery exercises; while at the Artillery College, Woolwich, officers are instructed in the manufacture of ordnance, &c. The School of Military Engineering, Chatham, is for the instruction of engineer officers and men in construction and estimating, practical fortification, surveying, submarine and military mining, and other subjects. Young officers on appointment from the Royal Military Academy remain under instruction and on probation at this school for two years. For officers of other branches of the service there are classes for instruction in field-works and surveying; for cavalry soldiers, a 'cavalry pioneers' course. For the Royal Military School of Music, Kneller Hall, see **BAND**. At the School of Gymnastic Instruction, Aldershot, officers qualify for the appointment of superintendent of gymnasiums, and non-commissioned officers or men for that of gymnastic-instructor. Within recent years, especially since the Great War, the system of officers' training corps has been developed, branches being attached to the universities and some of the public schools.

In India there is a Staff College at Quetta founded on the lines of Camberley. In Canada there is a Royal Military College at Kingston (1876), which offers commissions of all arms; and a similar one at Sydney will perform equivalent services for Australia. A South African Military School is situated at Roberts Heights.

Army Schools (see section thereon under **ARMY**) are provided for the general education of soldiers and their children; and 'garrison classes' under specially qualified staff-officers, generally graduates of the Staff College, for the technical instruction of officers studying for the examinations which they must pass before promotion to the ranks of captain and major.

For the United States Military Academy, see **WEST POINT**.

Militia is the name sometimes given to the troops of the second line of a national army. Though at first intended for home defence only, those troops are freely used to reinforce the regular army if the exigencies of the campaign require it. In several respects the militia of Great Britain, as it existed until 1908, differed from that of other European nations. It could only be sent out of the country if it volunteered and with the consent of parliament, and with few exceptions the men composing it had never served in the regular army.

It was a constitutional force raised under the sanction of parliament for the defence of the country against invasion. Organised by counties and cities, it was essentially a local force. In Anglo-Saxon times all men were required to bear arms as a sort of body-rent for the land they held, but it was Alfred who first organised the *fyrð* or general levy, making land the basis of numbers, and the family system that of discipline; so many families were a tything, ten tythings a hundred, and hundreds were united into county powers, each under its *heretoga*, dux, or duke. Each section of the community had not only to furnish its quota in time of war, but also to provide arms, keep them in repair, and train its men for so many days every year. After the Conquest the feudal troops deprived the general levy of its former importance; but it never ceased wholly to exist, and when the crown began to contend with the Norman barons it naturally found its most powerful instrument in the old *fyrð*. Henry II. established 'an assize of arms,' at which every holder of land was bound to produce one or more men, fully equipped and capable of fighting in the national defence. This annual assembly of the *fyrð* or general levy is first recorded after the Conquest in 1181, but it gradually fell into decay. In the years of the Armada the old shire levies, under the name of Trained Bands or Militia, as they now first came to be called, began to show signs of a more permanent organisation, though they still remained deficient both in discipline and drill. During the Civil War the trained bands for the most part sided with the parliament. After the Restoration the loyal parliament of Charles II. declared the disposition of the militia to be the undoubted right of his majesty, but as the crown now largely depended upon a mercenary army, the militia was much neglected until 1757, when, a large portion of the regular army being absent in the Seven Years' War, it was carefully organised for the defence of the kingdom. Important militia acts were passed in 1786, 1802, 1852, and 1882. In 1871 the control of the militia was transferred to the War Office from the lords-lieutenant, who still recommended for commissions. When in 1876 the United Kingdom was divided into 69 infantry regimental districts, each had its territorial regiment, consisting generally of two line battalions and two to nine militia battalions, besides the regimental depot, volunteer battalions, and the men in the Army Reserve and Militia Reserve. The latter were militiamen who, by taking a double bounty (£2) at the end of each training, rendered themselves liable in time of emergency to be drafted into the regular army. The Militia Reserve was established in 1867; enlistment for it ceased in 1901. The 'quota' or number of militiamen to be provided by each territorial district was fixed by government in proportion to the number of battalions in each such district. These numbers were to be raised by voluntary recruitment, serve six years, and might re-enlist for six more; but should volunteering fail, a levy by ballot would be made upon all the inhabitants of the locality between the ages of eighteen and thirty to serve five years. The power of making this ballot always existed, and would have by law to be enforced but for the annual Militia Ballot Suspension Act. Many classes were exempt from the ballot, as peers, volunteers, yeomanry, resident members of universities, clergymen, parish schoolmasters, articled clerks, apprentices, crown employés, and 'poor men' with children. From the year 1871 onwards many steps were taken to increase the efficiency of the militia and assimilate its position to that of the regular army. Large barracks were built at the headquarters of regimental districts, and camps

constantly formed; the officers were frequently employed with regular troops, both infantry and artillery; and recruits were trained under regular officers at district headquarters. The general status of the force was fixed by an act of 1882. Recruitment was for six months; annual training for not less than twenty-one days, with a possible extension to fifty-six days. The period of service was for six years, with re-engagement for the same period. The area of service was limited to the United Kingdom. When out for training or embodied, officers and men received the same pay as regular troops of corresponding arms of the service, and were subject to military law. Officers were at all times so subject; they ranked with, but were junior to, those of the regular army. Broadly speaking, the force might be embodied in any national emergency, and its services in this respect were frequently called for. Part or whole was called out from 1757 to 1763, from 1778 to 1783, from 1792 to 1803, and in 1815. Several battalions served in the Peninsula, and won high praise from the Duke of Wellington. During the Crimean War of 1854-56 the force was embodied, and provided garrisons for Malta and Gibraltar. It was embodied again during the Indian Mutiny of 1857-59, partially in 1885, and finally in 1899 for the South African War.

This war brought up once more the question of the relation of the militia to the regular army and its place in the scheme of national defence. The problem was solved in 1907-8 by the transformation of the force into the Special Reserve (see RESERVE). Hitherto it had been called on to give annually some 12,000 recruits in time of peace to the line, and then in time of war (as in 1899) invited to serve abroad with depleted battalions. Not only was it deficient in strength, but without organisation for war; and the Royal Commission of 1904 had declared that, by no fault of its own, it was unfit to take the field for the defence of the country. It was inevitable, therefore, that it should be drastically dealt with in any scheme of reconstruction. The policy which Mr Haldane (Lord Haldane) ultimately adopted was to abolish its existing constitution and use its substance to form a true reserve to the regular army. Thus, after the annual training of 1908, the old constitutional force, with its splendid record of patriotic service, ceased to exist either in name or in fact. At this time it consisted of 124 infantry battalions, 32 corps of garrison artillery, 3 field battalions, and 2 engineer corps. Its true descendant must be looked for in the Territorial Force (see VOLUNTEERS, &c.). Of the 124 battalions of infantry, 23 were disbanded, and the remaining 101 were converted into units of the Special Reserve—74 of these serving at the regimental depôts, and 27 being made extra-reserve battalions. The Royal Garrison Artillery Militia, except certain Irish corps, was converted into the Royal Reserve Artillery, and the engineer corps into reserve, siege, and railway companies, and the Royal Army Medical Corps Militia was disbanded. Then two Irish regiments of Imperial Yeomanry were at the same time re-formed into Special Reserve units. The new units for the most part corresponded territorially with the old militia units, and their substance was at first largely composed of transferred militiamen, the remainder being men directly enlisted under Part III. of the Territorial and Reserve Forces Act. The name Militia was restored to the Special Reserve in 1921.

The celebrated local militia was the former general levy; it was instituted in 1808, and suspended but not abolished in 1816. It consisted of a force for each county six times as numerous as the regular militia quota. The men were drawn

by ballot from those between the ages of eighteen and thirty, served four years, and were not paid bounties or allowed to find substitutes. The counties were liable to a fine of £15 for every man short of the quota. These troops could only be marched beyond their respective counties in the event of actual invasion, but were liable to be called out in case of rebellion. Their numbers reached in 1811 to 213,000 men.

The militia of Scotland was not organised until 1797, and in 1802 it was brought under the same rules as the English militia. The Irish militia (Protestants from sixteen to sixty) dated from 1715, and in 1809 was organised like the English force. The Channel Islands militia dates from 1201. Canada and other British oversea dominions and colonies have many of them a militia force. The militia of the United States is not a federal or national force unless when called into the national service; nominally it is a state organisation. See ARMY, LANDWEHR, and the articles on the several countries.

Miliukov, PAUL NIKOLAEVICH, Russian politician and historian, born in 1859, studied and afterwards lectured at Moscow, but dismissed in 1904 for his political leanings went abroad, lecturing in the United States. As political editor of the *Rech*, he took a leading part in forming the Constitutional Democratic party. At the revolution he was foreign minister under Prince Lvov, and on the seizure of power by the Bolsheviks escaped to Kiev and became editor of a journal in Paris. He has proved himself an able historian.

Milk is an opaque white fluid secreted by the mammary glands of the females of the class Mammalia, after they have brought forth their young, and during the period in which their offspring are too immature to live upon ordinary food. It is devoid of odour, except for a short time after its extraction; is of a slightly sweet taste, most commonly of a slightly alkaline reaction (except in the Carnivora, in which it is acid); and its average specific gravity (in the case of human milk) is 1.032.

When examined under the microscope milk is found to consist of numberless transparent globules, of very minute size, floating in a clear, colourless fluid, the milk plasma. These globules are composed of fat, and when milk has stood for some time the larger globules rise to the surface and form a layer of *cream*, which is therefore rich in fat and poor in other nutritive substances (presently to be described) that are found in the milk plasma. If the cream be agitated in a churn the surface tension, which keeps the fat in globular form, is overcome, and the fat runs together to form Butter (q.v.). The casein which exists in solution in the plasma is an albuminous substance combined with calcium phosphate. This calcium phosphate is necessary for its solution, and if its union with the albumen be interfered with, as by the addition of an acid, the casein separates out in microscopic filaments which interlace, enclosing the milk globules, and forming a more or less solid clot. If milk be allowed to remain in an open vessel in warm weather, a few hours will produce this result; the casein clots in little masses, and we say 'the milk has turned.' It is acid or sour to the taste, and contains micro-organisms (*Bacterium lacticum*), by whose agency these changes are brought about. These little microbes have the power of converting the milk sugar into lactic acid, which in its turn coagulates the casein. These microbes do not exist in milk freshly passed from the mammary glands; they must find their way into the milk, where they rapidly multiply; and, as their germs are very freely distributed, this occurs sooner or later. The dairy-keeper, by efficient ventilation and scrupulous clean-

liness, endeavours to keep his dairy and his milk as free from these organisms as possible, and the careful nurse scalds out the infant's bottle in order that they may not multiply, as they will readily do, in any stale milk, rapidly infecting the fresh milk each time the bottle is used. The casein is not only clotted by acids, but a secretion of the stomach called rennet has a similar action, and a preparation of this, made from the stomach of calves, is used in cheese-making. This clotting occurs in the stomach when we drink milk, and this is one reason why milk may disagree: in order to render it more digestible it may be 'sipped' or it may be taken with lime-water, for in this way the formation of large clots within the stomach may be avoided. In Cheese (q.v.) formed after the addition of rennet we have a rich supply of nitrogenous matter (casein) together with fatty matter derived from the milk globules held fast in the curd.

Milk contains a sugar—milk sugar—in solution, and in addition a rather large proportion of inorganic salts. It contains all that a child requires for the growth and nourishment of the body, and is manufactured at great expenditure of the mother's strength if continued beyond the normal lactation period of 7 to 9 months. The first milk that flows from the breast at the beginning of a lactation period is termed the *colostrum*, and is rich in casein and albumin. The colostrum has an aperient effect. After a few days the secretion becomes thoroughly established. In a healthy, well-fed woman this continues for some months, after which time the drain upon the energy of the mother's body renders the milk poorer and less nutritious. The milk contains the salts, chiefly of lime, from which the infant builds its skeleton. It is well known that many medicines taken by the mother are excreted in the milk; much nonsense is, however, believed in regarding the fatal and sudden injury done to children as a result of severe mental excitement on the part of the wet-nurse. See INFANT (FEEDING OF), BREASTS.

The following table gives the average percentage composition of human milk and that of various domesticated animals:

	Water.	Fat.	Milk Sugar.	Casein.	Albumin.	Ash.
Woman.....	88.2	3.3	6.8	1.0	.5	.2
Cow	87.4	3.7	4.65	3.0	.5	.75
Mare.....	89.8	1.17	6.89	1.70	.14	.3
Ass.....	90.12	1.26	6.5	1.32	.34	.46
Goat.....	86.04	4.63	4.22	3.49	.86	.76
Elve.....	79.46	8.63	4.23	5.23	1.45	.95
Bitch.....	75.47	9.57	3.08	6.10	5.05	.73

Disease is very frequently transmitted by milk, not only from using contaminated water for washing the milk cans and for adulterating it, but also from the cow itself (see TYPHOID FEVER, SCARLATINA). It is not improbable that many obscure tubercular conditions are thus acquired by children.

Condensed milk is generally prepared from that of the cow, sweetened by the addition of ordinary cane sugar, and evaporated to about $\frac{1}{3}$ of its bulk. While hot it is poured into tins and sealed up. When used for food the milk may be diluted with six or seven times its volume of water, but in the case of infants the dilution must be more liberal. It is, however, never advisable to make use of condensed milk for the feeding of infants.

Milk is frequently adulterated, chiefly with water (see ADULTERATION). In this case a given volume of milk will contain an abnormally small number of fat globules. As these fat globules are the cause of the opacity of milk, a thin layer of milk will, if adulterated, be less opaque than a similar layer of unadulterated milk. At Lactometer (q.v.) is described the apparatus for testing the opacity and consequent dilution of milk. Unskimmed milk should yield in standing 12 to 24

parts per cent. of cream, and its specific gravity should be 1.028 to 1.034. Skimmed milk is heavier—1.032 to 1.040. In order to avoid the adulteration of milk a standard has been adopted by Government which requires that whole milk should contain not less than 3 per cent. of fat and 8.5 per cent. of other solids. See DAIRY, and for substitutes COW-TREE, SOYA.

Milk-fever. The establishment of the secretion of milk about two days after delivery is occasionally the cause of considerable constitutional disturbance, with all the symptoms of the feverish state. This occurs especially when the infant is not applied soon enough to the breast, and especially when the mother is kept on too low a diet; a fact which probably explains the much greater frequency of the condition in former times, when such treatment was considered necessary. The disturbance of health is not serious, and passes off when the breasts are emptied.

In the lower animals, also, milk-fever comes on within a few days after parturition. One variety, common to most animals, consists in inflammation of the membranes of the womb and bowels, and is produced by exposure to cold, overdriving, or injury during labour; it is best treated with oil and laudanum, tincture of aconite, fomentations to the belly, and antiseptics such as carbolic acid (largely diluted) injected into the womb itself. The other variety, to which alone the term 'milk-fever' is usually applied, is almost peculiar to the cow. This disease, though designated a 'fever,' is accompanied by a sub-normal temperature. It attacks animals in high condition, that are good milkers, and have already borne several calves, and consists in congestion of the brain and large nervous centres, and impairs all the vital functions, leading to dullness, loss of sensation, stupor, and complete unconsciousness. The treatment consists in giving the animal attacked 1 oz. chloral hydrate with 8 lb. treacle, repeating half the dose in half-an-hour if there is no motion of the bowels. As the treatment produces intense thirst, large quantities of water must be given to the cow. Preventive measures consist in giving the cow laxative foods before and after calving, in drawing small amounts of milk at frequent intervals, never completely emptying the udder during the first three days. The disease is particularly prevalent in dairies where the practice of removing the calf from the cow immediately after birth is followed. The above method of milking during the first few days follows the natural method of the calf in sucking.

Milk-tree. See COW-TREE, SAPOTACEÆ.

Milk-weed. See ASCLEPIAS.

Milkworts are various species of plants of the order Polygalææ or Polygalacææ. The order comprises about 10 genera and 700 species, which are widely distributed over the tropical and sub-tropical parts of the world; several species are natives of North America and of Europe. They are herbaceous plants or shrubby, occasionally in the latter case being of climbing habit. The leaves are usually simple and destitute of stipules; the flowers are irregular. Their qualities are generally tonic and slightly acid; and some are very astringent.—The Common Milkwort (*Polygala vulgaris*) is a small perennial plant, growing in dry hilly pastures, with an ascending stem, linear-lanceolate leaves, and a terminal raceme of small but very beautiful flowers, having a finely-crested keel. It varies considerably in size, in the size and even shape of the leaves, and in the size and colour of the flowers, which are sometimes of a most brilliant blue, sometimes purple, pink, or white.—*P. Senega* is a North American species, with erect

simple tufted stems, about one foot high, and terminal racemes of small white flowers. The root, which is woody, branched, contorted, and about half an inch in diameter, is the Senega Root, Seneka Root, or Snake Root of the United States, famous as an imaginary cure for snake-bites, but really possessing important medicinal virtues—stimulating, diuretic, diaphoretic, emmenagogue, and in large doses emetic and purgative—employed in catarrhs, pulmonary affections, rheumatism, low fevers, &c. Its chief active principle is Polygalic Acid, $C_{22}H_{18}O_{11}$. The root of *P. Senega* has been employed as a cure for snake-bites by the American Indians from time immemorial, and it is a curious fact that *P. crotalariaoides* is employed in the same way in the Himalayas. *P. vulgaris* is tonic, stimulant, and diaphoretic; and *P. amara*, a very similar European species, possesses the same properties in a higher degree, as does

Common Milkwort
(*Polygala vulgaris*).

P. rubella, a small North American species. The root of *P. angulata*, a Brazilian species, with leathery leaves, is an active emetic, and in a fresh state is employed in bilious fevers. *P. tinctoria*, a native of Arabia, furnishes a blue dye like indigo. *P. venenosa* is by the natives of Java dreaded on account of its noxious heavy odour, which they say causes severe headache and violent sneezing. Rhatany (q.v.) Root was placed in this order by Benthams and Hooker. The bark of the roots of *Monnina polystachya* and *M. salicifolia* is used in Peru as a substitute for soap; and *Mundtia pinosa*, a South African shrub, produces an eatable fruit.

Milky-way. See GALAXY.

Mill. This word is now used in a general way as a name for almost all kinds of manufactories, as well as for machines used for grinding; but in this article we shall describe only a flour-mill. For other mills, see SPINNING, WEAVING, COTTON, FLAX, WOOL, &c.

From time immemorial, until comparatively recent times, wheat was always ground between two stones. At first hand-mills were used such as are still met with amongst uncivilised peoples (see QUERN); but the mill subsequently passed through many mechanical developments up to large merchant mills, some of which contained upwards of 100 pairs of great millstones. These were made of 'buhr,' a very hard silicate, the best stones coming from the valley of the Seine. The millstones were circular, usually about four feet in diameter, formed of wedged-shaped pieces strongly cemented together, and bound by iron hoops. The surfaces were cut into a series of radiating ridges and furrows, by which means the wheat was pushed from the centre to the circumference of the stones, as well as broken between the edges of the ridges. Great care had to be taken that the surfaces of the

two stones were perfectly level and perfectly parallel to each other. Only the upper stone or runner revolved, the lower or bedstone being fixed. The first successful steam flour-mill was erected in London in 1784.

Iron rollers in place of millstones were first practically tried at the roller mill in Pest, founded in 1840 by the patriot Count Szechenyi. This new system, called the high grinding or gradual reduction roller system, ultimately spread throughout Hungary, and made Budapest for many years the greatest flour-milling centre in the world. By 1875 this system had been adopted by the millers of the north-western states of America; and it enabled them to outstrip their teachers: Minneapolis is now the largest flour-milling centre in the world. Since 1880 this system has been universally adopted. The great advantage of rollers over millstones is found to be that the former avoid the rasping of the outside of the wheat berry which was inseparable from millstones, and produced a small quantity of very dark powder which necessarily mixed with the flour and greatly deteriorated its colour.

The following is a description of the different processes which together form the high-grinding or gradual reduction system of flour-milling. (1) The wheat is cleaned by means of sifting, winnowing, and being put through a cylinder of wire-cloth, with rapidly revolving arms inside, which combines the actions of sifting and polishing the wheat. A machine furnished with hard brushes may be employed to scrub the wheat; which is often also cleaned by washing, and is subsequently dried by passing through hot air. (2) The cleaned wheat is sent to grooved chilled-iron rollers (see fig. 1), and slightly broken between them; the product is sifted by means of cylinders covered with wire-cloth or silk-gauze, by which means a proportion of flour is separated, mixed with a substance composed of small pieces of the floury part of the wheat berry, and called usually 'middlings,' sometimes 'semolina.' The pieces of broken wheat are sent to other rollers to be again broken, and the product sifted as before. This process is repeated from four to seven times, according to the ideas of the miller and the nature of the wheat, until, as far as possible, all the floury part has been scraped from the husk or 'bran,' which is sold for fodder.

Fig. 1.—Roller Mill.

We are thus left with the mixture of flour and 'middlings' from the four to seven breaking processes. The products from the different breaking processes are generally mixed together and then sifted as before described, in order to separate the flour which is then ready for use from the 'middlings,' which are then put through the process called 'purification.' It may here be mentioned that the making of a large quantity of 'middlings' is the principal difference between the former

'low-grinding' and the present 'high-grinding' system, and is the chief advantage of the latter. By the former process it was sought to reduce the wheat at one grinding as far as possible into flour and bran: it was, however, found to be impossible to keep the two separate, a portion of finely-powdered bran being inevitably mixed with the flour, greatly to the detriment of the latter. By high-grinding the floury part is reduced in the first instance principally to a granular state, and, though bran particles are mixed with the flour granules, they may be almost entirely separated, owing to the difference in their specific gravity, by means of this process of purification. (3) The size of the granules of the middlings varies from that of fine sand to that of a pin's head. The middlings are therefore first separated by sifting into as many sizes as may be thought desirable, and each size is sent to one or more machines called middlings purifiers. These are of two types, called gravity and sieve purifiers. In the first type, which is generally used for the large sizes of middlings, the material is directly acted on by a draught of air. The machine usually takes the form of a series of sloping boards or of revolving discs, by either of which devices the middlings are caused to fall repeatedly in a thin even stream through a current of air produced by a revolving fan. As the specific gravity of the flour granules is greater than that of the bran particles, it is obvious that the current of air may be so regulated as to carry away the particles of bran, leaving the flour granules to fall to the bottom of the machine.

The sieve purifier generally takes the form of an oblong box, or case, of wood; occupying the centre plane of this case a sieve formed of silk-gauze is supported on springs, and is made to oscillate by means of a crank. A revolving fan is placed at the top of the machine, which draws air through the meshes of the sieve, the current of air being so regulated that the branny particles are either carried away by the draught to a suitable receptacle or are kept suspended on the top of the sieve until they are carried over the end of it, while the heavier flour granules fall through the sieve. This type of machine is always used for the smaller sizes of middlings. It is the dust drawn from these machines by the fans that, when mixed in a certain proportion with air and accidentally ignited, has caused several very serious explosions in flour-mills. The middlings, after being thoroughly cleaned (by repetition of the process when necessary), are ground between smooth chilled-iron rollers and the product sifted; the flour thus produced is of fine quality, and is usually called 'patent' flour.

Fig. 2.—Centrifugal Dressing Reel.

Fig. 2 represents one type of cylinder used for sifting (technically, dressing) the products in flour manufacture. These cylinders are of two

kinds, the ordinary reel or cylinder being a frame-work covered round with wire-cloth or silk-gauze and made to rotate, thus setting in motion the enclosed material. The other type is called a centrifugal dressing machine (see fig. 2). In this machine, in addition to the rotating cylinder, there is a frame with long pieces of wood or iron attached, made to revolve independently inside the cylinder. By this means the material is thrown against the circumference of the cylinder, so that a much smaller surface is required than in the ordinary reel to do the same amount of work. The 'Plansichter,' introduced in Budapest in 1888, which, as its name implies, is a horizontal sieve, has a special contrivance for keeping the material in motion and the meshes clear. This machine, with or without modifications, is now largely used in place of cylinders. Almost all modern mills are constructed on what is termed the automatic system, which means that all the conveyance of the material from one point in the mill to another is done by mechanical means; so that of the great bulk of the flour it may be said that it is never stopped or touched on its journey from the time it leaves the wheat sack until it reaches the flour sack. The conveyer generally used to move material in a horizontal direction is a helical screw (sometimes called an Archimedean screw); and to lift to a higher level an elevator is used.

In recent years certain chemical processes have been in use in some mills. One process for bleaching the flour is to pass the flour through air containing a small proportion of dioxide of nitrogen gas, generated either by chemical reaction or by passing the air through an electric flame. Another process is to mix a small quantity, not more than .3 per cent., of phosphate of lime with the flour; this improves what is called 'strength' in flour, i.e. the power when made into dough of rising under the action of a ferment.

Mill (Lat. *mille*, 'a thousand'), in the United States, is the tenth part of a cent, the thousandth part of a dollar. As a coin it has no existence.

MILL, JAMES, was the son of a shoemaker, and was born in Logie-Pert parish, near Montrose, Scotland, 6th April 1773. He studied, with a view to the church, at the university of Edinburgh, where he distinguished himself in Greek and in Moral and Metaphysical Philosophy. He was licensed to preach in 1798; but instead of following out the ministry, he went to London in 1802, where he settled as a literary man. He became editor of the *Literary Journal*, which after a time was discontinued; and wrote for various periodicals, including the *Eclectic* and the *Edinburgh Review*. In 1806 he commenced his *History of British India*, which he carried on along with other literary work, and published in the winter of 1817-18. The impression produced by this masterly history on the Indian authorities was such, that, in 1819, the Court of Directors of the Company appointed him to the high post of Assistant-examiner of Indian Correspondence, notwithstanding the then unpopularity of his well-known radical opinions. The business assigned to his care was the revenue department, which he continued to superintend till four years before his death, when he was appointed head of the examiner's office, where he had the control of all the departments of Indian administration—political, judicial, and financial—managed by the Secret Committee of the Court of Directors. Shortly after his appointment to the India House, he contributed the articles on Government, Education, Jurisprudence, Law of Nations, Liberty of the Press, Colonies, and Prison Discipline to the *Encyclopædia Britannica*. These essays were reprinted in a separate form, and became widely known. The powers of analysis, of

clear statement, and of the thorough-going application of principles, exhibited in these articles, had probably never before been brought to bear on that class of subjects. In 1821-22 he published his *Elements of Political Economy*, a work prepared primarily with a view to the education of his eldest son, John Stuart Mill. In 1829 his *Analysis of the Human Mind* appeared. His last published book was the *Fragment on Mackintosh*, brought out in 1835. He was also a contributor to the *Westminster Review* and to the *London Review*, which merged in the *London and Westminster*.

Not long after he settled in London, he made the acquaintance of Jeremy Bentham, and for a number of years lived during the summer in Bentham's country-house. Although he must have derived much benefit from his intercourse with the great law-reformer, he was not a mere disciple of Bentham, but a man of profound and original thought, as well as of great reading, in all the departments of moral, mental, and political philosophy. His conversation was impressive to a remarkable degree, and he gave a powerful intellectual stimulus to a number of young men, some of whom (including his own son, and Grote, the historian of Greece) afterwards rose to eminence. He took a leading part in the founding of University College, London. He died at Kensington, 23d June 1836.

See the Autobiography of J. S. Mill; Bain, *James Mill* (1882); Leslie Stephen, *English Utilitarians* (1900).

MILL, JOHN STUART, the eldest son of James Mill, was born in London on 20th May 1806. He was educated by his father, by whom he was subjected from his earliest years to a careful and systematic training, which was to fit him to carry on the work and champion the opinions with which the elder Mill was identified. Almost from infancy his intellect was on the strain. He is said to have begun Greek at the age of three, and before he was fourteen he had read extensively in Greek, Latin, mathematics, and English, had begun logic and political economy, and already possessed the intellectual acquirements of a well-educated man. But he was secluded from companions of his own age. As he himself says, he 'never was a boy.' His nearest approach to recreation was the long walks—in reality peripatetic oral examinations—for which he was regularly taken by his father. In 1820 he went to France on a visit to the family of Sir S. Bentham (Jeremy Bentham's brother), and was thus removed for more than a year from his father's immediate influence. His studies were never intermitted. His residence in France not only gave him a keen interest in French politics and social conditions, but stimulated his botanical enthusiasm, and the love for scenery and travel, which became the chief relaxations of his arduous life. After his return home he worked at history and law, and read the English and French philosophers. His first published writings appeared in the *Traveller* newspaper in 1822. In the following year a career was secured for him by an appointment under his father at the India Office, from which he retired as head of his department in 1858, on the transfer of the Company's government to the crown. At the same time he declined a seat in the new India Council offered to him by Lord Derby. During the years 1823-26 he was a member of a small Utilitarian society which met for the purpose of discussion at Jeremy Bentham's house. The name 'Utilitarian' was suggested by an expression in one of Galt's novels, and seized upon by him 'with a boy's fondness for a name and a banner,' to describe himself and others of like opinions. In the Speculative Society, which was founded in 1825, and of which he remained a member till 1829, he met men of a greater variety

of creeds, and formed an intimate friendship with Maurice and Sterling, Liberals of a different type from those he had met at his father's house, and influenced by Coleridge, not by Bentham.

Before he was twenty, Mill was recognised as the champion and future leader of what may be called the Utilitarian School in philosophy and politics, and had become the most frequent contributor to the newly-established organ of the party, the *Westminster Review*. But the 'mental crisis' through which he passed at this time (1826-27) led to a modification of his attitude. Bentham's *Treatise on Legislation*, which he had read four or five years before, formed the keystone of his previous position. It gave him 'a creed, a doctrine, a philosophy; in one among the best senses of the word, a religion; the inculcation and diffusion of which could be made the principal outward purpose of a life.' The crisis under which his enthusiasm for his old creed and opinions broke down was attributed by himself not merely to a dull state of nerves, but to the purely intellectual education which weakened his sympathies at the same time as it taught him to analyse and trace them to their origin. He ultimately emerged from the state of depression by discovering that feeling was not dead within him. The experiences of this period left, he tells us, two very marked effects on his opinions and character. In the first place, they led him to a new theory of life in relation to happiness. The conviction was forced upon him that happiness—although the test of all rules of conduct and the end of life—was only to be obtained by not making it the direct end, but by having one's mind fixed on some such ideal end as the improvement of mankind, or even some art or pursuit. His 'mental crisis' further led him to see the necessity for human well-being of the internal culture of the individual. He ceased to attach almost exclusive importance to the ordering of outward circumstances, and to the forced training of the human being for thought and action. And soon after this time he found in Wordsworth's poems 'the very culture of the feelings' he was in quest of.

The wider appreciation of speculation and literature brought about by this new attitude may be seen in his reviews of Tennyson's poems (1835), and of Carlyle's *French Revolution* (1837), as well as in his article on Coleridge (1840). His article on Bentham (1838) made clear the extent of his divergence from his inherited creed, and gave rise to the 'admiration mixed with fear' with which Grote and others of the school regarded him. In this article can be traced the lines along which, in his subsequent writings, he modified the traditional creed of Bentham and James Mill. Perhaps the reaction from Benthamism would have gone further had it not been for the friendship with Mrs John Taylor (whom he first met in 1830, and whom he married in 1851), which formed the romance of his life. It is indeed hardly possible to estimate her influence so highly as Mill did himself. All his leading opinions were formed before he made her acquaintance, and some of his most important works were completed without her assistance. But she did exert great influence on the expression of his views, and apparently had a steadying effect on his philosophical position.

Mill never forsook, though he modified, the leading principles of the philosophy in which he was educated. He held that knowledge could be analysed into impressions of sense, and that the principle of association was the great constructive force which combined these sensations and their copies, or ideas, into systems of thought, modes of feeling, and habits of acting. His *System of Logic* (1843)—perhaps the most original and important of his works—traces, and gives a

rationale of, the way in which the real, disjointedly given in sensation, is combined into scientific knowledge. Its treatment of the methods of inductive science—in which it owes much to Herschel, Whewell, and Comte—has become classical. His *Examination of Sir W. Hamilton's Philosophy* (1865), and edition of James Mill's *Analysis of the Phenomena of the Human Mind* (1869), contain a polemical defence and exposition of the association-psychology, notable for their clear recognition of the mental elements which that psychology assumes without explanation. His essay on *Utilitarianism* (1861) defends the greatest-happiness theory, but suggests modifications inconsistent with it (see the article ETHICS). He held that government was to be purified and made into a utilitarian instrument by means of representative institutions; but he had less confidence than Bentham and his father had in the effect of reason and argument upon men, disapproved of an equal suffrage, distrusted the ballot, and argued eloquently for individual liberty of thought and action against the tyranny of the majority (*Considerations on Representative Government*, 1861; *Thoughts on Parliamentary Reform*, 1859; *On Liberty*, 1859). His *Principles of Political Economy* (1848) is a systematic treatise, which does not depart in its main teaching from the theory laid down in abstract fashion by Ricardo; but it recognises more clearly the hypothetical character of this theory, and it discusses the social applications of economic doctrines. Mill was M.P. for Westminster from 1865 to 1868. In parliament he voted with the advanced Radical party; and his advocacy of women's suffrage in the debates on the Reform Bill of 1867 led to an active movement for placing the legal and political rights of women on an equality with those of men. Mill died at Avignon, 8th May 1873, and was buried in the cemetery there.

In addition to the works already mentioned, Mill was the author of *Essays on some unsettled Questions of Political Economy* (1844), *Auguste Comte and Positivism* (1865), *England and Ireland* (1868), *Subjection of Women* (1869). After his death were published *Autobiography* (1873; complete edition 1925), and *Three Essays on Religion* (1874). His more important occasional writings are collected in four volumes of *Dissertations and Discussions* (1859-75). For his life and opinions, see biographies by A. Bain (1882) and W. L. Courtney (1889), and a study by C. M. Douglas (1895).

MILL, JOHN, a New Testament critic, was born about 1645, at Shap in Westmorland, entered Queen's College, Oxford, as servitor in 1661, and was successively fellow and tutor of his college, rector of Blechington in Oxfordshire (1681), principal of St Edmund's Hall (1685), and prebendary of Canterbury (1704). He died 23d June 1707, just fourteen days after the publication of his great *Novum Testamentum Græcum*, with its thirty thousand various readings, the labour of thirty years.

Millais, SIR JOHN EVERETT, P.R.A., painter, was born at Southampton, 8th June 1829, the descendant of an ancient Jersey family. In the winter of 1838-39 Millais began to attend the drawing academy of Henry Sass, passing, two years later, into the schools of the Royal Academy. At the age of seventeen he exhibited at the Royal Academy his 'Pizarro seizing the Inca of Peru,' ranked by competent critics of the day as on a level with the best historical subjects then shown. Till now his work had been upon the lines of art generally current in England at the time; but there followed a phase of revolt from accepted standards, a period of search for new paths. He became associated with the knot of young artists known as the Pre-Raphaelite Brotherhood, of whom the other chiefs were Dante Gabriel Rossetti and Holman Hunt; and undoubtedly he was.

markedly influenced by the powerful personalities of both of these men, and by Mr Ruskin their literary ally. From them, in particular, his art received an impetus towards imagination and symbolism, which—as has been proved by the curious absence of such qualities from his later and more independent productions—were to a great extent foreign to his native genius. His marvellous technical skill enabled him to embody in visible artistic form conceptions that were essentially those of others with far greater adequacy than their own less trained hands could possibly have done. His first Pre-Raphaelite picture, a scene from the *Isabella* of Keats, strongly recalling the manner of the early Flemish and Italian masters, figured in the Academy in 1849, where it was followed in 1850 by the striking 'Christ in the House of his Parents,' known as 'The Carpenter's Shop,' in 1851 by 'The Woodman's Daughter,' in 1852 by 'The Huguenot' and 'Ophelia,' and in 1853 by 'The Order of Release' and 'The Proscribed Royalist.'

In 1856 he was elected an Associate of the Royal Academy, and soon afterwards he exhibited three of the richest and most poetic of the productions of his Pre-Raphaelite period—the 'Autumn Leaves' in 1856, the 'Sir Isumbras at the Ford' in 1857, and 'The Vale of Rest' in 1859. In the finer of the works which followed, such as 'Charlie is my Darling' (1864)—the year in which the painter received full academic honours—'The Minuet' (1866), and 'Rosalind and Celia' (1868), the precision and clear definition of Pre-Raphaelite methods still survive; but in the exquisite 'Gambler's Wife' (1869) there became visible a larger and freer method of handling, which is yet more fully established in 'The Boyhood of Raleigh' (1870), a picture which, retaining a measure of the imaginative charm of his earlier subjects, marks the transition of his art into its final and, technically, most masterly phase, displaying all the brilliant and effective colouring, the effortless power of brush-work, and the delicacy of flesh-painting. The interest and value of his later works lay mainly in their splendid technical qualities. In great part they are actual or fancy portraits, varied by a few important landscapes, of which in many ways the finest is 'Chill October' (1871), and by such an occasional figure-piece as 'The North-west Passage' (1873) and 'Effie Deans' (1877). Millais executed a few etchings, and his innumerable illustrations, dating from about 1857 to 1864, and most of them published in *Good Words*, *Once a Week*, and the *Cornhill Magazine*, placed him in the first rank of woodcut designers. He was D.C.L. of Oxford; in 1885 he was created a Baronet; he was elected P.R.A. in February 1896, and died 13th August of the same year.

See Armstrong's *Life and Work of Millais* (1885); Sir W. Richmond, *Leighton, Millais, and William Morris* (1898); M. H. Spielmann, *Millais and his Work* (1898); and *Life and Letters* (1899) by his fourth son, John Guille Millais, who, born in 1869 and educated at Trinity, Cambridge, became a clever animal painter, and wrote and illustrated many books of natural history.

Millau, on the Tarn, 52 miles NW. of Montpellier. In the 16th and 17th centuries it was a stronghold of the Calvinists. Leather and gloves are manufactured, and in wool there is a good trade. Pop. 15,500.

Millay, EDNA ST VINCENT, born 22d February 1892 at Rockland, Maine, studied at Vassar College, and lived in New York. Ere nineteen she revealed a remarkable lyric gift in 'Renascentia,' which gave its title to her first volume of verse (1917). *Figs from Thistles* (1920), *Second April* (1921), and *The Harp-Weaver* (1924) bore out the promise. *Aria da Capo* is a poetic play. She also writes short stories.

Millbank Prison, or THE PENITENTIARY, demolished in 1891, was in Westminster, near Vauxhall Bridge. It was erected at an enormous cost to carry out the plans of the philanthropists Howard and Bentham; the latter's contract with the Treasury was signed in 1794, but the building was not actually commenced till 1812, and not completed till 1821. It had accommodation for 1100 prisoners, and was so constructed that, from a room in the centre, the governor was able to view every one of the cells, in which solitary confinement was rigidly enforced. Convicts condemned to penal servitude used to undergo first a term of solitary confinement in Millbank; but the prison ceased to be a convict establishment in 1886, and was finally closed in November 1890. The Tate Gallery now occupies its site. See books on Millbank by Griffiths (1875-97).

Millboard is the name given to 'board' made of paper material, and varying in thickness from $\frac{1}{8}$ th to $\frac{1}{4}$ th of an inch. It is of a gray colour, as the various kinds of waste substances—old ropes, old sacking, scraps of paper and of cardboard—from which it is usually made are not bleached either separately or when mixed and reduced to a pulp, as in the manufacture of white paper (see PAPER).

Mille, PIERRE, 'the French Kipling,' editor of *Le Temps*, born in 1865 at Choisy-le-Roi, wrote *Barnavaux* (trans. 1915), *Louise and Barnavaux* (1916), and other tales.

Milledgeville, the former capital of Georgia (q.v.), 32 miles ENE. of Macon; pop. 4600.

Millenary Petition. See HAMPTON.

Millennium (Lat., 'a thousand years'), a long indefinite space during which the kingdom of the Messiah will, according to the belief of many Christians, be visibly established on the earth. The idea originated proximately in the Messianic expectations of the Jews; and the Christians' belief in the *Parousia*, or Second Coming of Christ, was developed by the oppression and persecutions to which they were long subjected. The chief basis of the millenarian idea, in Judaism as well as in Christianity, is the ardent hope for a visible divine rule upon earth, and the identification of the church with that of which it is merely a symbol. In the 1st century of the church, chiliasm (the Greek equivalent of millenarianism, from *chilioi*, 'a thousand') was a widespread belief, to which the books of Daniel and the Apocalypse (chaps. xx. and xxi.) gave authority; while various prophetic writings, composed at the end of the 1st and the beginning of the 2d century—such as the *Testament of the Twelve Patriarchs*, the *Christian Sibylline Books*, the *Epistle of Barnabas*—lent it a more vivid colouring and imagery. Not only the heretic Cerinthus, but even orthodox doctors—such as Papias of Hierapolis, Irenæus, and Justin Martyr—delighted themselves with dreams of the glory and magnificence of the millennial kingdom. The *Sibylline Books*, for instance, hold that the earth will be cultivated throughout its length and breadth, that there will be no more seas, no more winters, no more nights; everlasting wells will run honey, milk, and wine. Papias indulges in monstrous representations of the rebuilding of Jerusalem, and of the colossal vine and grapes of the millennial reign.

According to the general opinion, which was as much Christian as Jewish, the millennium was to be preceded by great calamities. The personification of evil appeared in *Antichrist* (q.v.), the precursor of Christ (identified during the 1st century with Nero), who would provoke a frightful war in the land of Magog (Ezek. xxxviii. and xxxix.) against the people Gog, after which the Messiah would appear, heralded by Elias, or Moses, or

Melchizedek, or Isaiah, or Jeremiah, and would bind Satan for a thousand years, annihilate the godless heathen, or make them slaves of the believers, and overturn the Roman empire. From its ruins a new order of things would spring forth, in which the 'dead in Christ' would arise, and along with the surviving saints enjoy an incomparable felicity in the city of the 'New Jerusalem,' which was expected to descend literally from heaven. With the innocence which was the state of man in Paradise there were associated, in the prevalent notions of the millennium, great physical and intellectual pleasures.

The lapse of time, chilling the ardour of the primitive Christian belief in the nearness of the *Parousia*, had without doubt also the tendency to give a more shadowy, and therefore a more spiritual aspect to the kingdom over which the expected Messiah was to reign. The influence of the Alexandrian philosophy contributed to produce the same result. Origen, for example, started the idea that, instead of a final and desperate conflict between Paganism and Christianity, the real progress and victory of Christianity would consist in the gradual spread of the truth throughout the world, and in the voluntary homage paid to it by all secular powers. Yet even in the Egypto-Alexandrian Church millenarianism, in its most literal form, was widely diffused. The Montanists (see MONTANISM) generally were extreme millenarians or chiliasts, and, being considered a heretical sect, contributed largely to bring chiliasm into discredit, or, at all events, their own carnal form of chiliasm, which Tertullian himself attacked. Lactantius, in the beginning of the 4th century, was the last important Church Father who indulged in chiliastic dreams. In the 5th century, St Jerome and St Augustine expressly combated certain fanatics who still hoped for the advent of a millennial kingdom whose pleasures included those of the flesh. From this time the Church formally rejected millenarianism in its sensuous 'visible form,' although the doctrine every now and then made its reappearance, especially as a general popular belief, in the most sudden and obstinate manner. Thus, the expectation of the *Last Day* in the year 1000 A.D. reinvested the doctrine with a transitory importance, though less than is sometimes thought.

At the period of the Reformation, millenarianism once more experienced a partial revival, because it was not a difficult matter to apply some of its symbolism to the papacy: the pope, for example, was Antichrist. Yet the doctrine was not adopted by the great body of the Reformers, but by some fanatical sects, such as the Anabaptists, as also by various theosophists in the next century. During the civil and religious wars in France and England it was also prominent; the Fifth Monarchy Men (q.v.) of Cromwell's time were millenarians of the most exaggerated type. The extravagances of the French Mystics and Quietists culminated in chiliastic views. During the Thirty Years' War enthusiastic and learned chiliasts flourished. Among the foremost chiliastic teachers of modern centuries are to be mentioned Ezechiel Meth and Bishop Comenius in Germany; Professor Jurieu of Sedan, and Poiret; Serarius in Holland; and in England Joseph Mede (*Clav. Apocal.* 1627), while Thomas Burnet and William Whiston endeavoured to give chiliasm a geological foundation. Most of the chief divines of the Westminster Assembly were millenarians; so were Sir Isaac Newton and Bishop Horsley. Bengel revived an earnest interest in the subject among orthodox Protestants. Spenser and Joachim Lange held chiliastic views; and Swedenborg employed apocalyptic images to set forth the transfigured world of the senses. Bengel's millenarianism was adopted by the Swabian theosophist

Oetinger (died 1782), and widely spread throughout Germany by Jung Stilling, Lavater, and Hess. Charles Wesley and Toplady were millenarians.

Modern millenarians or pre-millenialists (as believing in the pre-millennial advent of Christ) differ in many minor points from one another, but agree in holding that the millennial age will be heralded by the personal return of the Lord Jesus, to establish a theocratic kingdom of universal righteousness, during which time sin will remain on earth but be greatly diminished. Immediately on Christ's appearing will take place the resurrection of the righteous dead and the translation of living Christians, who will be rewarded according to their works. The judgment work of Christ will occupy the whole millennial period. The Jews, restored to their own land, will repent and be converted. All the hosts of Antichrist will be destroyed, Satan bound, and the Holy Ghost poured out. At the end of the millennial age Satan released will make a last vain attempt to regain his power, but he and the wicked, who now have their resurrection, will be finally judged and cast into the lake of fire. The earth will be renewed by fire, and be the scene of the everlasting kingdom of Christ over all sanctified mankind. Attempts to fix the date of the advent are generally disapproved. Dates that have been fixed for the beginning of the millennium have been 1785 by Stilling, 1836 by Bengel, 1843 by Miller in America, 1866, 1867, and 1868 by Dr Cumming, and 1890 by the Mormon Church. Some adventists teach the doctrine of Apocatastasis (q.v.), others the final annihilation of the impenitent. See ADVENTISTS (SECOND), and HELL.

Many great German theologians were more or less pronouncedly pre-millenialists; such as Rothe, Hofmann, Nitzsch, Ebrard, Lange, Delitzsch, Christlieb, Luthardt, as also Oosterzee, Gausson, and Godet. The Free Church of Italy and the Plymouth Brethren collectively hold these views. The Irvingites expect the speedy appearance of Christ. Pre-millennial views appear in the works of many eminent Anglicans—such as Archbishop Trench, Bishops Ellicott and Ryle, Canons Fremantle and Hoare, Dean Alford. Amongst Presbyterians Dr John Cumming and Dr Horatius Bonar are conspicuous names.

Millepede, a popular name for the members of one of the orders of Myriapods, of which *Julus* is a good type. See CENTIPEDE, MYRIOPODA.

Millepore. See CORAL.

Miller, HUGH, a distinguished self-taught geologist and author, was born at Cromarty, 10th October 1802. He was descended from a family of sailors, and lost his father by a storm at sea when he was five years of age. From his seventeenth to his thirty-fourth year he worked as a stone-mason, devoting his enforced winter leisure to literary study and research in natural history. In 1824-25 he worked at Niddrie, near Edinburgh. In 1829 he published *Poems written in the Leisure Hours of a Journeyman Mason* (1829), which was followed by *Scenes and Legends of the North of Scotland* (1835). His attention was soon drawn to the ecclesiastical controversies which were agitating Scotland, and his famous *Letter to Lord Brougham* on the 'Auchterarder Case' brought him prominently into notice. In 1834-39 he acted as bank-accountant; in 1839 he was invited to Edinburgh by Dr Candlish and Robert Paul, who had read his famous letter, as editor of the *Witness*, a newspaper started in the interest of the Non-intrusion party in the Church of Scotland; and in 1840 he published in its columns a series of geological articles, which were afterwards collected under the title of *The Old*

Red Sandstone, or New Walks in an Old Field (1841). These articles were very remarkable, from both a scientific and a literary point of view. They contained a minute account of the author's discovery of fossils in a formation believed, until then, to be destitute of them, and were written in a style which harmoniously combined strength, beauty, and polish. He was warmly praised by Murchison, Agassiz, and Buckland. Agassiz 'would give his left hand to possess such powers of description as this man.' Miller's editorial labours during the heat of the Disruption struggle were immense, and educated the people for the climax in 1843. He used the term 'Free Church' before the Disruption. In 1847 he had to vindicate his position as editor in a private pamphlet against clerical interference, and may be said to have come off triumphant. But, after years of hard, earnest, fagging toil, his brain gave way, and he shot himself, 23d December 1856. Miller contributed to Wilson's *Tales of the Borders* (1835) and *Chambers's Journal*. Chalmers said of him that when he did go off he was a great gun, but he required a deal of time to load. Yet he contributed at least a thousand articles to the *Witness*, 'complete journalistic essays, symmetrical in plan, finished in execution, and of sustained and splendid ability. Miller's works, besides those already mentioned, are *First Impressions of England and its People* (1847), the record of a journey to England in 1845; *Footprints of the Creator, or the Asterolepis of Stromness*, in which he combated the evolution theory (1850); *My Schools and Schoolmasters, or the Story of my Education* (1854); and *Testimony of the Rocks* (1857), an attempt to reconcile the Genesis with geology; *Cruise of the Betsey* (1858), being geological investigations among the islands of Scotland; *Sketch Book of Popular Geology*, with preface by Mrs Miller (1859); *Headship of Christ* (1861); *Essays, Historical and Biographical* (1862); *Tales and Sketches* (1863); *Edinburgh and its Neighbourhood* (1863); *Leading Articles* (1870). Besides his autobiography, see Lives by Bayne (1871), and Leask (1896), and Sir A. Geikie's centenary discourse (1902).

Miller, JOAQUIN (1841-1913), the pen-name of Cincinnatus Heine Miller, an American poet, born in Indiana. Removing with his parents to Oregon, he became a miner in California, was with Walker in Nicaragua, and afterwards lived with the Indians till 1860. He then studied law in Oregon, and set up in practice in 1863, after a Democratic paper that he edited had been suppressed for disloyalty. He was a county judge from 1866 to 1870, and then visited Europe; in England his first volume of verse was published. He afterwards settled as a journalist in Washington, and in 1887 in California. In 1890 he revisited England.

Miller, JOE. See JEST-BOOKS.

Miller, WILLIAM. See ADVENTISTS.

Miller, WILLIAM HALLOWS (1801-80), professor of Mineralogy at Cambridge, is especially distinguished for his system of Crystallography (q.v.).

Millerand, ALEXANDRE, born in Paris in 1859, studied law, edited socialist papers, was Minister of Commerce 1899-1902, of Public Works 1909-10, of War 1912-13, 1914-15, Commissaire Général in Alsace-Lorraine 1919, Premier January to September 1920, and President of the Republic (1920-4). He had an important part in the application of the Treaty of Versailles.

Miller's Thumb. See BULLHEAD.

Millet, a grain, of which there are several kinds, the produce of species of *Panicum*, *Setaria*, and allied genera. The genus *Panicum* contains

many species, natives of tropical and warm temperate countries, some of which, as Guinea Grass (q.v.), are amongst the largest fodder grasses. The flowers are in spikes, racemes, or panicles; the glumes very unequal, one of them often very minute; each spikelet containing two florets, one of which is often barren. The genus *Setaria* has a spike-like panicle, with two or more bristles under the glumes of each spikelet.—Common Millet (*Panicum miliaceum*) is an annual grass, three or four feet high, remarkably covered with long hairs, which stand out at right angles. It has a much-branched nodding panicle; the spikelets are oval, and contain only one seed. It is probably a native of Egypt or Asia, but is extensively cultivated in the warmer parts of Europe and other quarters of the world. The grain, which is very nutritious, is only about one-eighth of an inch in length. It is used in the form of groats, or in flour mixed with wheat-flour, which makes a good kind of bread; but bread made of millet alone is brittle and full of cracks. Poultry are extremely fond of millet.—Other species, *P. miliare*, *P. colonum*, and *P. pilosum*, are cultivated in different parts of India, chiefly on light and rather dry soils, yielding very abundant crops. Millet of various species is the staple food-grain of India as a whole, and not rice, as is often thought.—German Millet, or Mohar (*Setaria germanica*), and Italian Millet (*S. italica*)—regarded by many as varieties of one species, and probably originally from the East, although now naturalised in the south of Europe—are cultivated in many of the warmer parts of Europe, in India, and other countries. Italian millet is three or four feet in height; German millet is much lower, and its spike comparatively short, compact, and erect; it is less valuable as a corn-plant. The grains of both are very small, only about half as long as that of Common Millet; but they are extremely prolific, one root producing many stalks, and one spike of Italian millet often yielding two ounces of grain. The produce is estimated as five times that of wheat. The grain of these millets is im-

a, Common Millet (*Panicum miliaceum*); b, German Millet (*Setaria germanica*).

ported into Britain for feeding cage-birds. It is used for soup in the south of Europe. To the same tribe of grasses belong the genera *Paspalum*, *Pennisetum*, *Penicillaria*, *Digitaria*, and *Milium*. *Paspalum exile* is common in Africa; and *P. scrobiculatum* is cultivated on poor soils in India. *Pennisetum typhoideum*, often called Egyptian Millet and Guinea Corn, is cultivated in Africa and India, and the south of Europe.—*Pennisetum cenchroides* causes much inconvenience to the traveller in Central Africa, the little bristles which are attached to its seeds making them stick to the clothes and pierce the skin.—*Digitaria sanguinalis*, or *Panicum sanguinale* (Polish Millet), cultivated in Poland, is used like rice. It is a common grass

in tropical and warm countries and in many parts of Europe; in the south of England it is probably only an introduced weed. The spikes in this genus are compound, and from their appearance give it the names *Digitaria* and *Finger-grass*.—The Millet Grass (*Milium effusum*) of Britain, occasionally found in shady woods, is a very beautiful grass, three or four feet high, with a spreading pale panicle of small flowers. Another species of the same genus (*M. nigricans*) is the *Maiz de Guinea* of Peru, where its seeds are converted into a very white flour.—The name Indian Millet is sometimes given to Durra (q.v.).

Millet, JEAN FRANÇOIS, painter, was born in the village of Gruchy, near Gréville, on the 4th of October 1814. The son of a farmer, he owed much in his childhood to his grandmother, a woman of great piety and individuality, and to her brother, who had been a priest; and he was taught enough Latin to enjoy the Vulgate and Virgil. For a time he aided his father as a farm-labourer; but, having manifested great taste for drawing, he was at length, in 1832, placed under Monchel, a painter in Cherbourg, whom he assisted in the execution of two religious subjects now in the church of the Trinity there, and who induced the municipality of Cherbourg to grant an annuity to aid his pupil in his studies, the sum being afterwards supplemented by the council of La Manche. In 1837 Millet came to Paris, and worked in the studio of Paul Delaroche, learning, however, more from his study of the works of Michelangelo, Poussin, Correggio, and the Venetians. Next he painted and drew in pastels little subjects in the popular style of Boucher and Watteau, selling them to the dealers for a few francs; and in 1840 a portrait which he sent to the salon was accepted and hung. In the same year he returned to Normandy, where he painted portraits and even signboards. In 1841 he was again in Paris; and he struggled hard amid the revolutionary troubles that followed to maintain himself and his family by his art. In 1848 he fought at the barricades of the Quartier Roche-chouart; and in the following year he settled in Barbizon, near the Forest of Fontainebleau, along with Charles Jacque, and there made the acquaintance of Théodore Rousseau. At Barbizon, where he remained for the rest of his days, living much like the peasants around him, he began in good earnest to paint the life of rustic France, entering on his task with a sympathetic power such as no other painter has shown. Here the famous 'Sower' was completed in 1850, mainly, however, from recollections of Normandy. In 1855 his 'Peasants Grafting' won Gautier's praise, and was bought by an American for 4000 francs. It was followed by 'The Gleaners' in 1857, 'The Angelus' (1859), 'Waiting' and 'The Sheep-shearers' (1861), 'The Man with the Hoe' and 'Women Carding' (1863), 'Shepherdess and Flock' (1864), works in which, without any departure from the most absolute truth, he imparted a largeness and a pathetic dignity to his figures of the men and women who labour in the fields, and to their environments of ordinary nature. In addition to paintings, he produced many charcoal drawings of a very high quality, and he etched a few plates. All his life long he struggled against the pressure of poverty, though he was awarded medals and the Legion of Honour (1867). He died at Barbizon, 20th January 1875. Since his death he has been fully recognised as one of the greatest of French painters.

See works on Millet by Piédagnel (1876), Sensier (trans. 1881), Yriarte (1884), Ménard (1890), Roger-Miles (1895), Julia Cartwright (1896), Gensel (1902), Muther (1905); and D. C. Thomson, *The Barbizon School* (1890).

Millom, a town of Cumberland, on the west side of the Duddon estuary, 30 miles SSE. of Whitehaven, with mines and ironworks. Pop. 8700.

Millport. See CUMBRAE.

Millstone. See MILL.

Millstone Grit, a series of grits, sandstones, conglomerates, shales, &c., with coal-seams overlying the Carboniferous Limestone. See CARBONIFEROUS SYSTEM.

Millville, a city of New Jersey, on the Maurice River, 41 miles S. by E. of Philadelphia, with manufactures of cotton and glass; pop. 15,000.

Millwall, or ISLE OF DOGS, a low-lying peninsula on the left bank of the Thames, opposite Greenwich. See LONDON.

Milman, HENRY HART, dean of St Paul's, poet and ecclesiastical historian, was the youngest son of Sir Francis Milman (1746–1821), physician to George III., and was born in London, 10th February 1791. He was educated at Greenwich under Dr Burney, at Eton, and at Brasenose College, Oxford, where in 1812 he won the Newdigate with his *Belvidere Apollo*, the best of all Oxford prize poems. In 1815 he was elected a fellow; in 1816 was ordained priest, and appointed vicar of St Mary's, Reading; from 1821 to 1831 was professor of Poetry at Oxford, where in 1827 he delivered the Bampton Lectures, on *The Character and Conduct of the Apostles considered as an Evidence of Christianity*; in 1835 became rector of St Mary's, Westminster, and a canon of Westminster; and in 1849 was promoted to the deanery of St Paul's. He died at Sunninghill, near Ascot, 24th September 1868, and was buried in St Paul's.

The collected edition of Dr Milman's *Poems and Dramatic Works* (3 vols. 1839) comprises *Fazio, a Tragedy* (1815), which, without his consent, was acted first at Bath, and then in 1818 at Covent Garden, with Charles Kemble and Miss O'Neil in the leading parts; *Samor, Lord of the Bright City, an heroic poem* (1818); *The Fall of Jerusalem* (1820), a beautiful dramatic poem, with some fine sacred lyrics interspersed; three other dramas, *The Martyr of Antioch* (1822), *Belshazzar* (1822), and *Anne Boleyn* (1826); and *Nala and Damayanti, with other Poems translated from the Sanskrit* (1834). Forgotten as a whole, the poems live, and will live, through three or four much prized hymns—'When our heads are bowed with woe,' 'Brother, thou art gone before us,' and 'Ride on, ride on in Majesty.' The complete edition of Dean Milman's *Historical Works* (15 vols. 1866–67) includes his *History of the Jews* (1829), *History of Christianity to the Abolition of Paganism in the Roman Empire* (1840), and *History of Latin Christianity to the Pontificate of Nicholas V.* (1854–56). The last—a complete epic and philosophy of mediæval Christendom—is Milman's masterpiece; it is really a great work, great in all the essentials of history—subject, style, and research. But, though vastly inferior, the *History of the Jews* was in a way more important. For 'it was,' in Dean Stanley's words, 'the first decisive inroad of German theology into England; the first palpable indication that the Bible "could be studied like another book;" that the characters and events of the sacred history could be treated at once critically and reverently.' Milman also edited Gibbon and Horace, and wrote much for the *Quarterly Review*. After his death appeared the delightful *Annals of St Paul's Cathedral* (1868), and *Savonarola, Erasmus, and other Essays* (1870). See the Life of Dean Milman by his son (1900).

Milne, ALAN ALEXANDER, playwright, born in 1882, was educated at Westminster and at Cambridge, where he edited *The Grantha*. He became

a journalist, and in 1906-14 was assistant editor of *Punch*. His humorous comedies such as *Wurzel-Flummery* (1917), *Mr Pim Passes By* (1919), *The Romantic Age* (1920) have a happy fragrance. A book of verse *When We Were Very Young* (1924) was accepted at once among the children's classics.

Milne, JOHN (1859-1913), seismologist, was born at Liverpool, worked in Newfoundland as a mining-engineer, was for twenty years mining-engineer and geologist to the Japanese government, married a Japanese wife, became a supreme authority on earthquakes, and finally established a private seismological observatory at Shide, Isle of Wight.

Milne-Edwards, HENRI, naturalist, was born at Bruges, 23d October 1800. His father was an Englishman. Milne-Edwards studied medicine at Paris, where he took his degree of M.D. in 1823, but devoted himself to natural history. After having for many years taught natural history at the Collège de Henri IV., he was elected in 1838 member of the Académie des Sciences in the place of Cuvier. In 1841 he filled the chair of Entomology at the Jardin des Plantes, and in 1844 became also professor of Zoology and Physiology. He was a member of the Académie de Médecine, and of most of the learned academies of Europe and America, and held several orders—amongst others, since 1861, that of Commander of the Legion of Honour. He published numerous original memoirs of importance in the *Annales des Sciences Naturelles*, a journal he himself assisted in editing for fifty years. His *Éléments de Zoologie* (1834), when reissued in 1851 as *Cours Élémentaire de Zoologie*, had an enormous circulation at home and abroad, and long formed the basis of most minor manuals of zoology published in Europe. His *Histoire Naturelle des Crustacés* (1834-40) and *Histoire Naturelle des Corallaires* (1857-60) were almost equally noteworthy. The *Lectures on the Physiology and Comparative Anatomy of Man and the Animals* (14 vols. 1857-81) have a great permanent value for their immense mass of details and copious references to scattered sources. He had an important share in a splendid quarto of *Anatomical and Zoological Researches on the Coasts of Sicily*. He wrote also on the natural history of the French coasts (1832-45) and on the natural history of the mammalia (1871). His study of the distribution of the lower invertebrates led him to the theory of centres of creation; and to this he adhered throughout life, in spite of the general acceptance of the newer and larger views of Darwin. He died on the 29th July 1885. In some of his later works he was assisted by his distinguished son Alphonse (1835-1900). His elder brother, Frederick William, is considered the father of ethnology in France.

Milner, ALFRED, VISCOUNT, was born 23d March 1854 at Bonn, son of a university lecturer on English at Tübingen, studied at King's College, and concluded a brilliant career at Oxford with a New College fellowship. For a time he was assistant-editor of the *Pall Mall Gazette*; then private secretary to Goschen; in 1889-92 a signally successful under-secretary for Finance in Egypt. In 1892 he had published his valuable book *England in Egypt*. From 1892 he was chairman of the Board of Inland Revenue, until he was appointed governor of Cape Colony, 1897-1901; he was also High Commissioner for British South Africa, 1897-1905, and governor of the Transvaal and Orange River Colony, 1901-5. That he could have averted the South African War has been asserted and denied. He was responsible for the bringing of Chinese labour to South Africa. On his return to Britain he strove for imperialism and colonial preference, and pub-

lished *The Nation and the Empire* (1913). It was he who in 1909 bade the die-hards in the House of Lords reject the budget and 'damn the consequences.' The Great War, however, brought him into very different relations with Mr Lloyd George, in whose Coalition Ministry he was successively minister without portfolio, Secretary for War, and for the Colonies. His last act as Colonial Secretary was to recommend the granting of independence to Egypt (1921). *Questions of the Hour* appeared in 1923. He died 13th May 1925. He had been made G.C.B. and a baron in 1901, viscount in 1902, and a Knight of the Garter in 1921. See Worsfold's *Lord Milner in South Africa* (1906).

Milnes, RICHARD MONCKTON. See HOUGHTON.

Milngavie (pron. *Milguy'*), a town of Dumbar-tonshire, 7 miles NNW. of Glasgow; pop. 4400.

Milo. See MELOS.

Milo, of Crotona, in Magna Græcia, was six times victor for wrestling at the Olympic games, and as often at the Pythian, and commanded the army which defeated the Sybarites in 511. He is said to have carried a live ox upon his shoulders through the stadium of Olympia, and afterwards to have eaten the whole of it in one day. He lost his life in trying with his hands to split a tree, which closed upon him and held him fast until he was devoured by wolves.

Milreis, or CORÔA, a Portuguese gold coin and money of account, containing 1000 reis, superseded by decree of 1911 by the gold *escudo* (4s. 5½d.). The Brazilian milreis has a par value of 2s. 3d.

Miltiades, a celebrated Athenian general, who was tyrant of a colony in the Thracian Chersonesus, took part with Darius Hystaspes against the Scythians, and, when Attica was threatened by the great Persian invasion, was chosen one of the ten generals. He prevailed upon the polemarch Callimachus to give his casting vote in favour of risking a battle, and when his turn came to command drew up his army on the famous field of Marathon. The victory of the Athenians and one thousand Plateans over the Persian host of Datis and Artaphernes is justly counted one of the decisive battles of the world. Miltiades, being entrusted anew with the command of an armament, made an attack on the island of Paros in order to gratify a private enmity, but, failing in the attempt, was on his return to Athens condemned to pay a fine of fifty talents as an indemnity for the expenses of the expedition. Being unable to do this, he was thrown into prison, where he died of a wound received at Paros. The fine was exacted after his death from his son Cimon.

Milton, JOHN, after Shakespeare the greatest English poet, was born in Bread Street, Cheapside, on December 9, 1608. His father, John Milton, was a prosperous scrivener, a Puritan but a musician, and composer of several pieces much admired by his contemporaries. He was descended from a family of yeomen settled in Oxfordshire, and had come to town upon being disinherited for his religious convictions by his father, a Catholic recusant. He appears to have from the first discerned the promise of his son, and to have determined to give him the best education he could. After studying under private tutors, young Milton was admitted about 1620 into St Paul's School, where he distinguished himself not only as a scholar, but as a poet. In February 1625 he entered Christ's College, Cambridge. His academic course was not wholly smooth; he seems to have been chastised—not, as the legend says, flogged—by his tutor, and was certainly rusticated for a short time in 1626. After his return, however, he went through the university course with

credit, graduating as Bachelor at the proper time, and proceeding Master of Arts in July 1632. The condition of the church, over which Laud then ruled supreme, deterred the young Puritan from taking orders; he felt no vocation towards any other profession; and at Horton, in Buckinghamshire, where his father had retired upon the fortune he had acquired in business, he settled quietly down with the distinct purpose of making himself a poet by study and self-discipline. His poetical genius had already been attested by two noble productions, the 'Hymn on the Nativity,' and 'At a Solemn Music,' as well as much Latin verse of the highest quality; but it is remarkable how little stimulus he seems to have felt to occasional composition. During his six years' residence at Horton he produced, so far as known, only two English poems of importance which can be ascribed to direct poetical impulse from within, the *Allegro* and the *Penseroso*. *Comus* was written at the instance of his friend, the musician Henry Lawes, to celebrate Lord Bridgewater's assumption of the wardenship of the Welsh marches, and was performed at Ludlow before a select assemblage in September 1634. *Lycidas* was evoked by the death of his friend, Edward King, shipwrecked on his passage to Ireland in 1637. There is, perhaps, not another instance in literature of a great poet so entirely dependent upon circumstances for inspiration, and, while meditating the highest things, so content to bide his time in calm reliance upon his ability to do what he pleased when he pleased. These four productions of this Horton period were indeed of themselves sufficient to place him in the first rank of English poets. Their most individual characteristic is perhaps chastened exuberance—boundless poetical wealth severely controlled, and splendidly displayed without lavishness or ostentation. *Comus* and *Lycidas* tell us much of the man; in the former we see the scholar's disdain, perhaps slightly tinged with moroseness, for all save intellectual pleasures; in the latter the patriot and the Puritan speaks his bitter scorn of the ruling faction in the church. Perhaps he had spoken too freely; at all events very shortly after the publication of his elegy, about the beginning of 1638, as part of an obituary collection in memory of Edward King, he left England for a tour in Italy.

Milton's visit to Italy is one of the most agreeable chapters of his life. He was cordially received by the Italian literati, especially at Florence, where he made not only pleasant acquaintanceships, but permanent friendships. At Rome, notwithstanding his undaunted profession of Protestantism, he was treated with especial attention, and at Naples the venerable Marquis Manso, half a century earlier the protector of Tasso, gave him hospitality and presents, which Milton requited with an elegant Latin poem. The impression which Milton thus produced upon foreigners is a proof of something imposing and attractive in his personality, for all his solid claims to fame were of course a sealed book to the Italians. His journey home was hastened by news of the outbreak of hostilities between Charles I. and the Scots, and his return was saddened by tidings of the death of his friend Diodati, whom he celebrated in his elegy 'Damon,' the finest and the last of his Latin poems. He settled in St Bride's Churchyard, afterwards in Aldersgate Street, and devoted himself to the education of his sister's children, the two young Philipsses. Unconscious of the long farewell he was about to bid to poetry, he occupied his leisure with schemes for poems mostly dramatic and scriptural, of which numerous skeleton outlines are preserved. The conception of *Paradise Lost* as a mystery or miracle play

gradually dawned upon his mind, and Satan's address to the Sun was actually written about this time. But the Civil War came, and for long silenced Milton's muse, except for an occasional sonnet.

It has been much debated whether the world has lost or gained more by Milton's absorption in politics. The question is somewhat idle; to wish for Milton other than he was is to wish for a succession of *Comuses* rather than a *Paradise Lost*. No man capable of conceiving such a work as Milton's epic could be unaffected by the situation of his country at that tremendous crisis, and with Milton's poetical temperament lively interest in anything signified total occupation by it for the time. The tracts which he now poured forth are as truly lyrical inspirations as any of his poems; by no means masterpieces of reasoning, but dithyrambic ecstasies of love or hate. Three appeared in 1641, two in 1642. All five relate to church government: never was diction so magnificently called forth by a theme so unpromising. In fact, however, the writer's thoughts are much higher and deeper than his subject, and, stripped of what is temporary and accidental in the latter, they appear magnificent idealisations of the possibilities of a far-off future, which to Milton seemed ever at the door. The great drawback to their enjoyment at the present day is the scurrility of their invective, which passed comparatively unperceived amid the excitement of revolution.

In 1643 Milton's activity as a public writer was diverted into a new channel by private affairs, which, however, he so handled as to render of universal concern. In June of this year, after a very short courtship, he married a young lady, Mary Powell, daughter of an Oxfordshire squire, previously known to him as a debtor to his father for money advanced on mortgage. The bride's family were cavaliers, and she would seem to have been as little suited to her husband in every other respect as by her education and connections. The idealising imagination of the poet must in all probability have been at work, and the thoughtless precipitancy of the whole transaction would alone show how greatly in many respects the popular estimate of Milton's character needs revision. The poor girl was naturally shocked at the sudden transfer from a jovial country household to the apartments of an austere scholar, whose intellect and character she was utterly unable to appreciate, and whose principles ran counter to all her prejudices. After a few weeks' trial of matrimony she went back to her friends, under a promise, Milton's nephew says, to return at Michaelmas. She certainly did not return, and early in the following year Milton put forth another edition of his *Doctrine and Discipline of Divorce*, greatly extended, and enriched with erudition and argument. It brought many attacks upon him, mainly from the Presbyterians, from whose views on church and state he had been more and more dissociating himself. He replied to his opponents in three supplementary pamphlets, and a threat of prosecution by a parliamentary committee, which came to nothing, occasioned the production (November 1644) of the most famous of his prose-works, *Areopagitica*, a *Speech for the liberty of Unlicensed Printing*, which has come to be regarded as almost the gospel of freedom of speech, and, if less eloquent than his tracts on church government, nevertheless contains the best known passages of his prose-writings. It must be remembered that even here Milton does not contend against the prosecution of published opinions deemed pernicious, but merely against the right to forbid publication through the instrumentality of a licenser. A few months previously he had composed and

published, at the instance of his friend Samuel Hartlib, a *Tractate of Education*, of little practical pedagogic value, but full of inspiration and suggestion.

Milton was not the man to permit his opinions to remain empty speculations, and in the course of 1645 he was taking serious steps towards carrying the most obnoxious of them into practice by paying his addresses to 'a very handsome and witty gentlewoman,' when the absent wife thought it time to return. Her repentance may probably have been further stimulated by the overthrow of the Royalist cause, which had occasioned the total ruin of her family. Conscious, probably, of his own failings in temper and considerateness, Milton did not prove obdurate; and by September his household was re-established in the Barbican. She further induced him to receive her mother and other members of her impoverished family, persons whom he had little reason to love, and of whose incompatibility he complains in a letter to an Italian friend. Little else can be said of her, except that she brought him three daughters, and died in 1652. He lost the father to whom he owed so much in 1647, a year after the fruits of his education and the partial accomplishment of the purpose of his life had been manifested in a collected edition of his poetical works, English and Latin.

During all this time Milton's calling, apart from his studies and polemics, had been educational; other pupils, mostly sons of friends, had been gradually added to his nephews, and he seemed to the world a schoolmaster. He was now to enter public life. The execution of Charles I., January 30, 1649, was followed within a fortnight by his defence of the deed, *The Tenure of Kings and Magistrates*. Having thus definitively cast in his lot with the ruling party, he was appointed on March 15 to a post which no other man in England was so competent to fill, that of 'Secretary of Foreign Tongues,' whose duty it was to draft diplomatic correspondence with foreign powers, then carried on in Latin. Milton had few equals in that age as a Latinist, whether in prose or verse, and his public letters were an honour to himself and his country, but there is no reason to suppose that he was ever much more than the mouthpiece of the government. His services were more conspicuous in another department, his justification of the king's execution in his reply to Salmasius's *Defensio Regia pro Carolo I.*, a pamphlet whose publication had been a European event. Milton's *Pro Populo Anglicano Defensio* (1651) was pronounced, even by those who condemned it, a great controversial victory. In erudition, Latinity, and, it must be added, scurrility, the combatants were well matched, but Milton spoke from the heart, and Salmasius from a brief. This work, now so little read, made Milton famous all over Europe, and is memorable as the immediate occasion of the loss of his eyesight, deliberately yielded up by him in the cause of his country. By 1652 the impaired vision had wholly failed, and it was necessary to provide him with an assistant in his official duties. His domestic life at this period was tranquil, distinguished chiefly by his second marriage and the loss of his wife (1656-58), and the pleasing intimacy of young friends, recorded in his sonnets. The magnificent sonnet on the massacre of the Vaudois was written in 1655. Several controversial pamphlets with Alexander Morus followed his contest with Salmasius, chiefly remarkable for the fortitude and dignity of his references to his affliction, and for his flattering portraits of the great men of the Commonwealth, especially Cromwell. Always leaning to the more radical side, he had supported Cromwell in all his extra-legal measures, though the disappointment of his early republican

ideal must have cost him many pangs. He retained his secretaryship until the abdication of Richard Cromwell, when the condition of public affairs again made him a pamphleteer. His writings of this period, greatly inferior in splendour of diction to his first productions of the kind, are still most interesting as passionate protests, conclusive of his entire lack of practical statesmanship and his essentially poetical temperament. The Restoration drove him into concealment. Few had more bitterly exasperated the Royalist party; but the new government was not bloodthirsty, and about the beginning of 1661 he found himself settled in Jewin Street (afterwards in Artillery Walk, Bunhill Fields), honourably released from politics with the gratifying consciousness of having done his duty and his best, and free to devote himself entirely to the permanent purpose of his life.

Paradise Lost was probably commenced some time before the Restoration, and completed about 1663—a striking instance of rapid composition, considering the magnitude and perfection of the work, the interruption by political revolution, and the fact that Milton's poetical vein only flowed freely between the autumnal equinox and the vernal. It was chiefly composed at night, and necessarily dictated to some amanuensis, usually one of his daughters. Plague and fire for a time warred against the publication, which at length, after some difficulty on the licenser's part had been surmounted, took place in August 1667. Every one knows that the copyright was sold for five pounds: it is not always remembered that there were contingencies which would have raised his emolument to £20, that he received altogether £10, and that his widow compounded for the remainder for £8. The sale of thirteen hundred copies within twenty months is certainly no discredit to the taste of the age. Milton's claim to a place among the great poets of his country seems to have been admitted from the first, though in the absence of reviews his fame travelled slowly. The year 1671 witnessed the publication of *Paradise Regained*, probably written in 1665-66, and of *Samson Agonistes*, written later still. The former was composed at the suggestion of the Quaker Ellwood, working on the suspicion Milton could not but entertain that he had after all made Satan the hero of *Paradise Lost*. *Samson Agonistes*, dramatic in form, is lyrical in substance, a splendid lament over the author's forlorn old age, and the apostasy, as he deemed it, of his nation. Both pieces evince the continued tendency of his style towards simplicity, which sometimes degenerates into baldness. They are noble pendants to *Paradise Lost*, but the more their relation to this palmary work is studied the more one feels that it and it alone places him among the supreme poets of the world.

Milton's domestic life during this period had not been fortunate. The great cause of sorrow was the undutifulness of his daughters—very ordinary young women, it would seem, who felt no sympathy or admiration to counterbalance their natural impatience of their heavy task as his readers and amanuenses. The blind poet on his part was no doubt often stern and exacting; and on the whole the history of his household is one of sordid sadness up to his marriage (1663) with Elizabeth Minshull, a pretty and domestic woman of twenty-five, the daughter of a Cheshire yeoman. She restored comfort to his house, but failed to conciliate his daughters, who, after being taught embroidery at their father's expense, left to set up for themselves. The accounts we have of him in his later years convey a generally pleasing picture of a not uncheerful retirement solaced by music and the attention of friends. When the poetic impulse had departed he addressed himself vigorously to other

unfulfilled designs of his youth, writing the early history of England and endeavouring to amend men's conceptions of grammar and logic. These writings are indeed of little value; but his Latin *Treatise of Christian Doctrines*, though devoid of all pretensions to eloquence, is a memorable work. His theology had become profoundly modified in the course of his life; he is now an Arian as regards the person of Christ; he is indifferent to all rites and ceremonies; he is as anti-Sabbatarian as Luther; he would even tolerate polygamy. The charm of the treatise consists in its dignified candour, and the absence of all polemic virulence. The tranquillity of evening was indeed closing around him as he penned this last legacy, the MS. of which, confiscated and mislaid, was not to see the light for a hundred and fifty years. Reduced still further in means by losses through the great fire of 1666, but still above want; execrated as a regicide by the majority of his countrymen, but already acclaimed by the discerning as the first poet of his age; worn by attacks of gout, but cheerful and even joyous in the intervals of pain, he closed his chequered life on November 8, 1674. He was interred in St Giles's, Cripplegate.

Milton is one of the poets respecting whose place in literature there has been least question, whether as regards the literature of their own country or that of the world. He stands at the head of those epic poets whose themes have not, like Homer's or Virgil's, been national, and have not, like Dante's, condensed the essence of the belief of ages. He is indebted for this superiority partly to his felicitous choice of the finest subject which yet remained for epical treatment, partly to his exceptional qualifications for treating it, but most of all to the actual superiority of his genius. After Homer there is no poet to whom the sublime is so much a native element, who rises into it with so little apparent effort, and remains in it for so long together. Another circumstance which would alone make him a poet for the world is that in him and in him alone the Hebraic and the Hellenic spirit appear thoroughly at one. His theme and his creed connect him with the Scriptures, but his literary tastes and models are the tastes and models of the Renaissance. As an English poet he fills up the great gap which would otherwise yawn between the age of Shakespeare and the age of Dryden, and, like Wren in architecture, proves that the classical style is not necessarily synonymous with pedantry or inanity. In the artful harmony of blank verse he surpasses every English poet, though he may not have caught the 'wood-notes wild' of Shakespeare and his contemporaries. His magnanimity as a man matched his sublimity as a poet; but he had perhaps more than a usual share of the failings attendant upon the magnanimous character, and at first sight appears arrogant and unamiable. It is not until we consider that the circumstances of his life forced these characteristics into prominence, and that biographers have too commonly thought the softer and more familiar traits unworthy of record; until we remember that the company of this austere idealist was frequented by the young, and that the pleasures of the social hour have been exquisitely sung by him; above all, until we note his almost entire dependence for composition upon external impulse, the rashness of some of his actions and the chivalry of others, that we perceive him to have possessed his full share of the emotional temperament common to poets.

† The principal contemporary authority for Milton's life is his nephew, Edward Phillips. Toland has added some interesting notices. Symmons, Mitford, Todd, and others wrought usefully in their day in collecting and investigating particulars, but their labours were entirely superseded by Professor Masson (7 vols. 1859-94), who left

nothing unexplored, and whose verdict is in most cases decisive. Johnson's short biography, however, must always be read for its literary merit, and as a remarkable instance of insuperable antipathy striving to be just. Milton's Life has been written on a small scale by Mark Pattison ('Men of Letters,' 1880) and by Richard Garnett ('Great Writers,' 1889); and there is Sir Walter Raleigh's *Study* (1900). There is an excellent and comprehensive German biography by Alfred Stern (2 vols. Leip. 1877-79). Addison, Johnson, Channing, Macaulay, Bridges, and Saurat are especially distinguished among Milton's critics. There are editions of Milton's poems by Professor Masson (3 vols. 1874; new ed. 1890), Beeching (1900, 1903), Aldis Wright (1903), and Grierson (vol. i. 1925).

Milwaukee, capital of Milwaukee county, Wisconsin, and the largest city in the state, is situated on the west shore of Lake Michigan, at the common mouth of three improved and navigable rivers, 90 miles north of Chicago. The parked and terraced bluffs have an average height of 80 feet above the water. Milwaukee is beautifully built with light yellow bricks—to which it owes its name of 'the Cream City.' The streets are wide and parked between the roadway and the sidewalk, and are lined on either side by magnificent elms whose branches form an almost continuous arch in the residential parts. The public parks are extensive, and are connected by wide boulevards. A vast system of intercepting sewers is in operation, and the river is flushed by means of a huge tunnel from the lake. Among notable buildings are the Custom-house and Post Office, the County Court, the Chamber of Commerce, the Exposition Building (with a natural history collection), the Layton Art Gallery, the public library, and many fine business houses. Several of the railway depôts are handsome buildings, as is the City Hall.

Milwaukee, which is a great railway centre, is essentially a manufacturing city. Its products include grain, flour, lumber, knit goods, pork, foundry and machine-shop products, iron, steel, and brass goods, leather, boots and shoes, and tobacco. There are large flour-mills, enormously capacious elevators, and its shipments of wheat total about 10,000,000 bushels annually. Pork-packing is another great industry. Soft drinks are a product of importance. Milwaukee was founded in 1835, chartered in 1846, and grew prodigiously after 1880. It was visited by a serious fire in 1892, the loss being nearly \$6,000,000. There is active steamer trading on the lakes. Juneau Park is laid out on a bluff overlooking the river. Marquette university is situated here, and near the city is the National Soldiers' Home. Pop. (1870) 71,440; (1900) 285,315; (1920) 457,147.

Mīmāṃsā (from the Sanskrit *man*, 'to investigate'; hence, literally, investigation) is the collective name of two of the six divisions of orthodox Hindu philosophy. They are distinguished as *Pūrva-* and *Uttara-mīmāṃsā*, the latter being more commonly called *Vedānta*, while the former is briefly styled *Mīmāṃsā*. The object of the *Mīmāṃsā* is primarily to lay down a correct interpretation of such Vedic passages as refer to the Brāhmanic ritual, to solve doubts on matters concerning sacrificial acts, and to reconcile discrepancies—according to the *Mīmāṃsā*, always apparent only—of Vedic texts. But in the course of development of the system it has been expanded, especially by the philosophers Prabhākara (c. 600) and Kumārila (c. 700), to include critical discussions of the nature of knowledge and reality. See SANSKRIT LITERATURE, VEDAS.

Mimes, the name given by the ancients to certain dramatic performances, in which, with little attempt at art, scenes of actual life were represented, sometimes in improvised dialogue. The Greek mimes appear to have been invented by the

Greeks of Sicily and Southern Italy. They were a favourite amusement of convivial parties, the guests themselves being generally the performers. Sophron of Syracuse (about 420 B.C.) composed many in the Doric dialect, which were much admired, and which Plato was accustomed to read. Herodas (q.v.) or Herondas belonged to a later time.—The Roman mimes were not borrowed from the Greek, but were of native Italic growth. They were not only far ruder and coarser, but in some respects they were essentially different—the dialogue occupying a smaller place, and mere gesture and mimicry predominating. The humour and satire, however, were often genuine, though rough and even indecent, and they were greatly relished by all classes; the patrician Sulla was fond of them. Their most famous mimic poets were Decimus Laberius and Pub. Syrus.

Mimicry. The fact that insects belonging to very different groups often bear an extremely close superficial resemblance to each other has been known for a long period of time. The names given to various species of British moths are sufficient proofs of this. Such names as *Bombyliiformis*, *Apiformis*, *Bembeciformis*, &c., imply a recognition of the resemblance between these species and others belonging to an entirely different order. The meaning of such likenesses was, however, very imperfectly known until the appearance of H. W. Bates's classical paper in 1862. In this memoir the author shows that the species which has departed from the normal type of its group (the mimicker) is far rarer than the form which it resembles, while the latter (the mimicked)

is abundant and well defended by some special protection, such as the possession of an unpleasant taste or smell or the power of stinging. Bates's observations were conducted in tropical America, where abundant, conspicuous, slow-flying, nauseous butterflies (Ithomiinae and Heliconinae) are closely mimicked by Pierinae (the group containing our common garden white butterflies) and other butterflies, and in many cases by day-flying moths. Subsequent observation has confirmed Bates's suggestion. Wallace found numerous instances of mimicry among the Lepidoptera of India and the Malay Archipelago, and Trimen directed attention to similar facts among South African butterflies. The latter include the most remarkable instance of mimicry yet discovered. The male of an African swallow-tailed butterfly (*Papilio dardanus*) is typical in appearance, and possesses the characteristic 'tails' on the hind-wings: the female, except in Abyssinia and Somaliland, is utterly unlike the

male in the colouring and form of the wings, the 'tails' being entirely absent. While the female is so different from the male of its own species it appears in East Africa in three well-marked forms mimicking three different species of the nauseous genus *Danais*—viz. the black, pale buff-spotted *D. Echeria*, the black and white *D. niavivus*, and the black orange-brown and white *D. chrysippus* (see fig. 2A). In West Africa the local race of *P. dardanus* has a very similar male, and females mimicking *D. chrysippus* and the West African form of *D. niavivus* with the chief white marking less developed than in East Africa. In Uganda and the adjacent areas there is a very interesting addition in the form of a female mimicking one, and in some parts two, Acreine models of the genus *Planema*, black with an orange bar across the fore wing and white across the hind. Different female forms, as well as the non-mimetic males, have been bred in one family reared from the eggs laid by a captured female. While such remarkable changes have occurred on the mainland of Africa, the ancestral form from which these mimetic races have been developed has been preserved comparatively unchanged in the island of Madagascar, as the nearly related *Papilio meriones*, in which the female closely resembles the male and is non-mimetic. Similar races with sexes almost alike have been found in the Comoro Islands (*P. humbloti*) and in Abyssinia (*P. antinorii*). This example strongly enforces a conclusion also arrived at by Bates and Wallace—viz. that the females are far more frequently mimetic than the males. Wallace has explained this as an adaptation to meet the especial dangers incurred by the female during her slow flight when laden with eggs, and her exposure to attack during oviposition: The female butterfly is also more variable in pattern than the male, and therefore more often produces varieties which may lead to a mimetic form.

The examples selected for illustration were lent by Colonel Swinhoe; the figures are about half the natural size. Fig. 1 represents the male of the Indian and African *Hypolimnas misippus*: it is non-mimetic and very unlike the female, being distinctly marked with a large white patch bordered with iridescent blue on each of the four wings. The iridescence on the right wings appears to extend farther than on the left, because it is seen from a different angle. The male remains unchanged in the localities where its female alters in correspondence with the form it mimics. Fig. 2 is the commonest form of female, which mimics the above-mentioned *Danais chrysippus* (fig. 2A), occurring nearly all over the Old World tropics. In certain localities the latter butterfly is represented by a variety with white hind-wings (*Danais alcippus*); see fig. 3A. In other localities *alcippus* is mixed, in varying proportions, with *chrysippus*. There is also a similar variety of the female *Hypolimnas* (the *alcippoides* form) shown in fig. 3. Finally, in Aden and certain African localities there is another variety of the *Danais* (*D. dorippus*) without the black and white marks at the tip of the fore-wing, shown in fig. 4A; while the *Hypolimnas* also develops a similar form of female, seen in fig. 4—the *inaria* form. *H. misippus* is a far more wandering butterfly than *chrysippus*, and its forms of female do not keep true to the localities of the forms of its model because of frequent interbreeding with migrants from other areas.

The butterflies which afford models for mimicry chiefly belong to the two sub-families Danainae (including *Euploea*, *Danais*, and *Hestia*) and Acreinae, in addition to the Ithomiinae and Heliconinae of tropical America. There is some direct and much indirect evidence to show that all mimicked species are specially protected by an

unpleasant taste or smell. Wallace has concisely stated the conditions under which mimicry occurs, as follows: '(1) That the imitative species occur in the same area and occupy the same station as the imitated. (2) That the imitators are always the more defenceless. (3) That the imitators are always less numerous in individuals. (4) That the imitators differ from the bulk of their allies. (5) That the imitation, however minute, is *external* and *visible* only, never extending to internal characters or to such as do not affect the external appearance.' It should be added that the female forms of *H. misippus* referred to above are an exception to (1), that exceptions to (3) are liable to occur as a consequence of fluctuating numbers of model and mimic, and that, as regards (5), the imitation in flight, attitude, &c., implies changes in the deep-seated nervous system of the mimic.

Examples of mimicry are also well known in other orders of insects. The formidable Hymenoptera (including the hornets, wasps, bees, and ants) are frequently resembled by defenceless insects belonging to other orders, such as moths

(Lepidoptera), beetles (Coleoptera), flies (Diptera), &c. The most remarkable example yet described was discovered by W. L. Slater in tropical America. The leaf-cutting ants (*Ecodoma*) are extremely abundant in this part of the world, and present a very characteristic appearance, each homeward-bound ant carrying a piece of leaf vertically in its jaws. Slater found a homopterous insect which faithfully resembled an ant together with its piece of leaf. The latter was suggested by the thin compressed green body of the insect, and its profile was precisely like that of the jagged edge of the fragment of leaf held over the back of the ant.

The mimicking may be separated from the mimicked species by an interval still wider than that between the various orders of insects. Spiders in many parts of the world are defended by resembling the aggressive and justly respected ants. Again, many large caterpillars intimidate their foes by resemblance to snakes. The extraordinary prevalence of mimicry among insects is probably to be explained by their usual defenceless condition, and by their immense fertility and the rate at which

I. Colours which cause an animal to resemble some part of its environment, or to mimic the appearance of some other species (APATETIC COLOURS).		II. Warning and signalling colours which suggest something unpleasant to an enemy, or aid in the escape of other individuals of the same species (SEMATIC COLOURS).	III. Colours displayed in courtship (EPIGAMIC COLOURS). Ex.— <i>Bright colours of male birds.</i>
A. Colours which conceal an animal by causing it to resemble some part of its normal surroundings (protective and aggressive resemblance: CRYPTIC COLOURS).	B. False warning and signalling colours deceptively suggesting something unpleasant to enemies or attractive to prey (protective and aggressive mimicry and alluring colours: PSEUDOSEMATIC COLOURS).		
1. Concealment as a defence against enemies (protective resemblance: PRO-CRYPTIC COLOURS). Ex.— <i>Colours by which palatable insects are concealed</i> (see arts. Butterfly and Caterpillar).	1. Colours which deceptively suggest something unpleasant or dangerous to an enemy (protective mimicry: PSEUDAPOSEMATIC COLOURS). Ex.— <i>Hornet-like moth, snake-like caterpillar.</i>	1. Colours which warn an enemy off by denoting something unpleasant or dangerous (warning colours: APOSEMATIC COLOURS). Ex.— <i>Gaudy colours of nauseous or dangerous insects.</i>	
2. Concealment enabling an enemy to catch its prey (aggressive resemblance: ANTCRYPTIC COLOURS). Ex.— <i>Colours of tiger, lion, &c.</i>	2. Colours which deceptively suggest something attractive to prey, or enable an enemy to approach without exciting suspicion (alluring colours: PSEUDEPSEMATIC COLOURS). Ex.— <i>Mantis (Hymenopus), which attracts the other insects on which it feeds by resembling a pink flower.</i>	2. Colours which enable individuals of the same species quickly to recognise and follow each other (recognition marks: EPISEMATIC COLOURS). Ex.— <i>White tail of rabbit.</i>	

the generations succeed each other—conditions which strongly favour the rapid action of natural selection. Hence it is that other forms of deceptive resemblance are also especially characteristic of insects (see articles BUTTERFLIES and CATERPILLAR in this work). Mimicry is, however, by no means unknown in other animals. Thus, the gaudy colours of the deadly coral snakes (Elaps) of tropical America are mimicked by harmless snakes; and the powerful friar-birds are resembled by defenceless orioles in various Malayan islands. All the instances cited above illustrate protective mimicry—a resemblance which serves to defend the imitator from attack. Aggressive mimicry, in which the resemblance favours the attack of the imitator upon the mimicked species or upon species which accompany the latter, appears to be very doubtful. A stinging model may be attacked by a predaceous mimic, but in such instances it is probable that the resemblance is a protection against insect-eating enemies rather than an aid in the attack.

Mimetic appearances are often combined with other methods of defence; thus, many large caterpillars are well concealed by protective resemblance, and only assume the terrifying snake-like appearance when alarmed. It is of great interest to trace

the relation of mimicry to the other uses of colour in animals. This relationship is shown in the above table. The difference between mimicry and protective resemblance (with which it is often confused) will be seen when A is compared with B.

Deceptive resemblance between specially protected insects is also frequent—e.g. between Danaids and Euploea, or a Heliconine and an Ithomiine. These, however, are examples of common warning (synaposematic) colours rather than true mimicry, which is false warning or pseudaposematic. This resemblance puzzled Bates, and was finally interpreted by Fritz Müller. It is therefore often spoken of as Müllerian mimicry.

The term mimicry has been criticised as seeming to imply conscious volition on the part of the imitator. Such a misapprehension is unlikely to arise in any one who has read the literature of the subject. Authorities are agreed that the resemblance has been gradually produced by the operation of natural selection, which has ensured the persistence of all variations tending in the direction of some well-defended insect avoided by foes.

It is interesting to find that protective resemblance and protective mimicry are employed by the Vegetable Kingdom, although very rarely as com-

pared with the Animal. W. J. Burchell in 1881 observed a little South African Mesembrianthemum which closely resembled the rounded pebbles of its locality, and concluded that for this reason it 'may generally escape the notice of cattle and wild animals.' This observation has been confirmed and extended to other species, some of which resemble angular lichen-covered fragments of rock. The resemblance of the dead-nettle to the stinging-nettle, with which it is so commonly associated, appears to be a good instance of protective mimicry (Burchell, *Travels in the Interior of Southern Africa*).

See H. W. Bates, 'Butterflies of the Amazon' (*Trans. Linn. Soc.*, xxiii.); A. R. Wallace, 'Malayan Butterflies' (*Trans. Linn. Soc.*, xxv.), *Essays on Natural Selection, Tropical Nature, and Darwinism*; R. Trimen, 'South African Butterflies' (*Trans. Linn. Soc.*, xxvi.); Belt, *Naturalist in Nicaragua*; Poulton, *Colours of Animals* (Inter. Science Series), *Essays on Evolution*, with the references given.

Mimosoideæ, a sub-family of Leguminosæ, distinguished by regular flowers and petals valvate in bud. Over 1500 species are known, all natives of warm climates, a few only extending beyond subtropical regions in the southern hemisphere. The genera *Acacia* (q.v.) and *Mimosa* are the best known. To the latter genus belong the Sensitive Plant (q.v.), also a great variety of trees usually of beautiful foliage (though their leaves, as in *Acacias*, may be reduced to phyllodia) and often also of valuable timber. The fruits are often esteemed, but the roots and seeds not unfrequently possess drastic or even poisonous properties. They are also rich in tannin and gums.

Mimulus maculosus—var.
Arlequin.

Mimulus, a genus of plants of the family Scrophulariaceæ, having a prismatic 5-toothed calyx, a somewhat bell-shaped corolla, of which the upper lip is bilid and the lower lip trifid, two long and two short stamens, and a stigma of two lamellæ, which close together upon irritation. The species are mostly herbaceous plants, natives of America. Some of them are very frequent in flower-gardens, and many fine varieties have resulted from cultivation. They sometimes receive the name of *Monkey-flower*. *M. luteus*, a native of Peru and Chile, and there used as a potherb, has become naturalised in Britain. The little yellow-flowered Musk Plant of gardens and window-sills is *M. moschatius*, from Oregon and other north-western parts of America.

Mimusops. See BALATA, BULLET-TREE, SAPO-TACEÆ.

Mina (Gr. *mna*), a Greek weight and money of account, the sixtieth part of a Talent (q.v.) containing 100 Drachmæ (q.v.).

Mina Bird. See MYNA.

Mineans. See SEMITES, SABÆANS.

Minaret, Minar, a tall turret used in Saracenic architecture. It contains a staircase, and is divided into several stories, with balconies from which the muezzins summon the Mohammedans to

prayer—bells not being permitted in their religion—and is terminated with a spire or ornamental finial. The minaret is amongst the most beautiful features of Mohammedan architecture, and is an invariable accompaniment of the Mosque (q.v.). For an illustration, see ARABIAN ARCHITECTURE. In India *Minars*, or pillars of victory, are frequently erected in connection with mosques; some of these are lofty and splendid monuments, that of Kutab, at the Old Delhi (q.v.), being 47 feet in diameter at the base and 238 feet high. The form of the minaret was derived from the Pharos, the ancient lighthouse of Alexandria; and the name is from the Arabic *mandrat*, 'a lighthouse.'

Minas, capital of a wild, mountainous province (area, 4800 sq. m.; pop. 75,000) of the same name in southern Uruguay, 75 miles by rail NE. of Montevideo; a picturesque town; pop. 13,000.

Minas Geraes, the most populous state of Brazil, lies inland from Espirito Santo and south of Bahia, and has an area of 229,000 sq. m. Pop. 6,000,000. Lying wholly in the tableland, its surface is occupied with grass and bush-covered *campos*, rising, however, in the Serra do Espinhaço to 5900 feet. The principal rivers include the navigable São Francisco and the Rio Grande, which unites with the Paranaíba to form the Paraná. Agriculture and stock-raising are the chief industries. Some gold is still got, and diamonds, iron, and lead are mined. The inhabitants include very few whites; among the Indians the Botocudos (q.v.) are met with. Capital, Belo Horizonte (40,000).

Mince-pies, an important item of English Christmas fare, composed of very numerous ingredients (suet, raisins, apples, lemons, currants, figs, almonds, flavoured with nutmeg, cinnamon, ginger, &c.) variously compounded and baked in pastry. Formerly mutton or neat's-tongue was an essential ingredient. The shape of the crust was not originally round, but is said to have been intended to represent the manger in which the Holy Child was laid.

Minch, the channel separating the island of Lewis from the mainland of Scotland. It is 24 to 40 miles wide, and has a rapid current. The *Little Minch*, separating Skye from North Uist and the neighbouring islands in the Outer Hebrides, is 14 to 20 miles wide.

Minchinhampton, a market-town of Gloucestershire, $3\frac{1}{2}$ miles SSE. of Stroud. James Bradley is buried in the churchyard.

Mincio, a tributary of the Po, rises in south Tyrol, and flows as the Sarca 80 miles to Lake Garda, from which it issues as the Mincio, and after a southerly course of 93 miles past Mantua joins the Po from the left. It forms an integral part of the Quadrilateral (q.v.) or system of fortification defending North Italy, and has had several great battles fought in its vicinity, as Castiglione (1796), Solferino (1859), Custoza (1849 and 1866).

Mind. See PSYCHOLOGY.

Mindanao. See PHILIPPINE ISLANDS.

Minden, a Prussian town in Westphalia, on the Weser, 40 miles W. of Hanover. Till 1873 a fortress of the second class, it was already a town in Charlemagne's day, and suffered much in the Thirty Years' War, and again in the Seven Years' War, when, on 1st August 1759, the French were defeated here by an Anglo-Hanoverian army under Ferdinand of Brunswick and Lord George Sackville. It has a fine new bridge (1874), a Gothic town-hall, a Catholic church (till 1811 cathedral), built between the 11th century and 1379, and restored in 1864-85, manufactures of tobacco, beer,

brandy, glass, &c., and a considerable river trade. Pop. (1919) 25,986. See also MÜNDEN.

Mindere'rus Spirit, or SOLUTION OF ACETATE OF AMMONIA, is a valuable diaphoretic, much used in febrile diseases. It is prepared by adding ammonia or the carbonate of ammonia to acetic acid till a neutral liquid is obtained. It is sometimes applied hot on flannel in cases of mumps, while it has also been employed as an eyewash in chronic ophthalmia.

Mine. See MINING, MINES (MILITARY).

Minehead, a watering-place of Somersetshire, on the Bristol Channel, 25 miles NW. of Taunton. Till 1832 it was a parliamentary borough. Pop. of urban district, 6000.

Mineral Kingdom, the inorganic portion of nature. Under this term, however, are not included the inorganic products of organic beings, as sugar, resins, &c., although substances more remotely of vegetable or even animal origin are reckoned among minerals, as naphtha, bitumen, asphalt, &c. To the mineral kingdom belong liquid and gaseous, as well as solid substances; water, atmospheric air, &c. are included in it. All the chemical elements are found in the mineral kingdom, from which vegetable and animal organisms derive them; but many of the compounds which exist in nature belong entirely to the vegetable and animal kingdoms, and are produced by the wonderful chemistry of life.

Mineralogy, the science which treats of minerals, does not embrace all that relates to the mineral kingdom. *Simple minerals* alone, or homogeneous mineral substances, are regarded as the subjects of mineralogy; rocks formed by the aggregation of simple minerals, and their relations to each other, are the subjects of Geology (q.v.). This limitation of the term mineralogy is comparatively recent. Geology or geognosy was formerly included in it. The arrangement and description of simple minerals according to their external characters has been called by Werner and others *Oryctognosy*, but the term has fortunately fallen into disuse. Nor is the study of mere external characters sufficient in mineralogy. Equally important are the internal molecular structure (as revealed by optical methods) and the chemical composition. The external physical characters, such as lustre, hardness, tenacity, &c., are now regarded as *inessential*, since they vary in different specimens of the same mineral. In modern scientific mineralogy the *essential* properties, such as chemical composition, specific gravity, and crystalline form, rank as of first importance.

Some minerals being of great use, and others highly valued for their beauty, have received much attention from the earliest ages. But the ancient naturalists describe few minerals. The first attempt at scientific mineralogy was by George Agricola in the 16th century. The systems of the Swedes Wallerius and Cronstedt, in the later half of the 18th century, were the first worthy of the name. That of Werner followed, and was extensively adopted. The discoveries of Haüy in crystallography, and the progress of chemistry, gave mineralogy a new character; and then sprang up two schools of mineralogists, one resting chiefly on external characters, and the other on chemical composition.

The chemical classification of minerals is rendered difficult by the endless variety of combination and proportion in the elements of which they are composed, the presence of substances not essential to the mineral, and yet more or less affecting its characters, and the frequent impossibility of determining what is to be deemed essential and what accidental. Chemical purity is almost never found

in nature. Even the purest diamond, when burned, leaves some traces of ash; and the various colours of diamond, quartz, and other minerals are due to the presence of substances which are often in so small quantity as not to affect their crystalline forms or other physical properties. Again, some minerals of identical chemical composition differ in their crystallisation, so that an arrangement founded upon it would separate them too widely. There are also many minerals which are often found in an uncrystallised state, and others which are always so. In the arrangement of minerals into natural groups, their chemical composition, although not alone to be regarded, is of the first importance, so that the place of a new mineral in the system can never be determined without analysis; and in determining the nature of a mineral chemical tests, such as the application of acids, are continually resorted to. It is also necessary to know its specific gravity, and how it is acted upon both by a moderate heat and by the blowpipe. An examination of the crystalline forms, with measurement of the angles of the crystals, is often sufficient to distinguish minerals which have otherwise much resemblance. The *cleavage* of crystals is also important—a readiness to split in planes parallel to certain of their faces only, by which the *cleavage form* of the crystal may be ascertained. Minerals not crystallised exhibit important varieties of *structure*, as *laminated*, *fibrous*, *granular*, &c. Certain peculiarities of *form* are also frequently characteristic of uncrystallised minerals, as *mammillary*, *botryoidal*, &c. Minerals exhibit, when broken, very different kinds of *fracture*, as *even*, *conchoidal*, *splintery*, &c. *Opacity*, *translucency*, and *transparency* are more or less characteristic of different kinds: *electric* and *magnetic* properties demand attention; and very important characters are derived from *lustre*, which in some minerals is *metallic*, in others *semi-metallic*, in others *pearly*, *vitreous*, &c. *Colour* is not generally of much importance, but in some minerals it is very characteristic. The colour of the powder formed when a mineral is scratched often differs from that of the solid mass. This is the *streak* of the mineral, and is frequently very characteristic. *Hardness* and *tenacity* are very important, and are of all various degrees. *Ungtuousity* and other peculiarities to be ascertained by the touch are very characteristic of some minerals, and peculiarities of *taste* and *smell* belong to others.

Mineralogy has very important relations with geology, which cannot be studied without regard to the mineral constituents of rocks. The mineral composition of soils greatly affects vegetation and agriculture. The economical uses of minerals are also very important and various. It is enough merely to allude to salt, sulphur, borax, alum, graphite, cryolite, native metals, metallic ores, &c. Naphtha, petroleum, bitumen, asphalt, &c., are of well-known utility; and a high value has always been attached to gems and other ornamental stones. There are special handbooks by Tschermak, Dana, Brush and Penfield, Miers, &c. See GEOLOGY, CRYSTALLOGRAPHY.

Mineral Oil. See BAKU, FUEL, INTERNAL-COMBUSTION ENGINE, NAPHTHA, PARAFFIN, PETROLEUM.

Mineral Tallow, or HATCHETTITE, a remarkable substance found in several places in Britain, Germany, Siberia, &c., soft and flexible, yellowish white, yellow, or greenish yellow, resembling wax or tallow, often flaky like spermaceti, inodorous, melting at about 115° F., and composed of about 86 per cent. carbon and 14 per cent. hydrogen. It is closely related to other solid hydrocarbons, such as ozokerite and native paraffin. Like most hydro-

carbons, such as naphtha, petroleum, asphalt, &c., Hatchettite appears to have resulted from the chemical alteration of organic matter.

Mineral Waters, spring waters which possess qualities in relation to the animal body different from those of ordinary water, have been used as remedial agents from a very early period. The oldest Greek physicians had great faith in their curative power, and the temples erected to Asklepios were usually in close proximity to mineral springs; the warm baths of Calirhoe, near the Dead Sea, are mentioned by Josephus as having been tried by Herod in his sickness. We are indebted to the Romans for the discovery not only of the mineral thermic springs in Italy, but of some of the most important in other parts of Europe, amongst which may be named Aachen, Baden-Baden, Bath, Spa in Belgium, and many others; and Pliny (*Natural History*) mentions a very large number of mineral springs in almost all parts of Europe (see BATH, HYDROTHERAPY). The therapeutic action of mineral waters or spas depends chiefly upon their chemical composition and their temperature, though other circumstances, as situation, elevation, climate, geological formation, mean temperature, &c., have an important bearing upon the success of the treatment.

The best time for undergoing a course of mineral waters is, in the majority of cases, the months of June, July, August, and September. There are, however, exceptions depending upon climate; for example, at Gastein, celebrated for its thermal springs, the weather is changeable and stormy in June and July, but pleasant in May, August, and September. Early rising is usually advisable during a course of mineral waters, and, as a general rule, the water should be drunk before breakfast, at intervals of about a quarter of an hour between each tumbler, moderate exercise being taken in the intervals. In many cases bathing is of even greater importance as a remedial agent than drinking. Baths are generally taken between breakfast and dinner, and should never be taken soon after a full meal. The time during which the patient should remain in the bath varies very much at different spas, and the directions of the local physician should be strictly attended to on this point. As a general rule, the treatment should not be protracted beyond the space of six weeks or two months, but on this point the patient must be solely guided by the physician resident at the spa. Indulgence in the pleasures of the table, and excesses of any kind, may counteract the salutary effects of the waters, while perfect mental relaxation is an important auxiliary to the treatment. Spas are only suitable for patients suffering from *chronic disorders*.

No classification of mineral waters based upon their chemical composition can be strictly exact, because many springs are, as it were, intermediate between tolerably well characterised groups. The following classification is perhaps the most convenient: (1) Alkaline Waters; (2) Bitter Waters; (3) Muriated Waters; (4) Earthy Waters; (5) Indifferent Thermal Waters; (6) Chalybeates; (7) Sulphurous Waters; (8) Arsenical Waters.

(1) The Alkaline Waters are divisible into (a) *Simple Alkaline Effervescent Waters*, of which the chief contents are carbonic acid and bicarbonate of sodium. The most important spas of this class are the thermal springs of Vichy and the cold springs of Fachingen, Geilnau, and Bilin. These waters are useful in certain forms of indigestion, in jaundice arising from catarrh of the hepatic ducts, in gallstones, in renal calculi and gravel, in gout, in chronic catarrh of the respiratory organs, and in abdominal plethora. Vichy (q.v.) may be taken as the representative of this class of springs. (b)

Muriated Alkaline Effervescent Waters, which differ from the preceding sub-group in additionally containing a considerable quantity of chloride of sodium. The most important spas of this kind are the thermal springs of Ems, and the cold springs of Selters and Salzbrunn. They are useful in chronic catarrhal affections of the bronchial tubes, the stomach and intestines, and the larynx; while the Ems waters possess a high reputation in certain chronic diseases of the womb and adjacent organs. (c) *Alkaline Saline Waters*, of which the chief contents are sulphate and bicarbonate of soda, such as the warm springs of Carlsbad and the cold springs of Marienbad, serviceable to patients suffering from abdominal plethora, if unconnected with diseases of the heart or lungs. These waters, especially those of Carlsbad, afford an excellent remedy for the habitual constipation which so frequently arises from sedentary occupations.

(2) The chief contents of the Bitter Waters are the sulphates of magnesia and soda; and the best-known spas of this class are those of Sedlitz, Friedrichshall, and Kissingen; although two valuable English examples are the bitter water of Cherry Rock, near Kingswood, in Gloucestershire, and the Purton Spa, near Swindon, in Wiltshire. These waters act both as purgatives and diuretics.

(3) The Muriated Waters are divisible into (a) *Simple Muriated Waters*, of which the chief contents are a moderate quantity of chloride of sodium or common salt. The chief spas of this class are Wiesbaden and Baden-Baden, which are hot; those of Soden (in Nassau), of Mondorf (near Luxembourg), and of Canstatt (near Stuttgart), which are tepid; and those of Kissingen, Homburg, and Cheltenham, which are cold. The muriated saline springs of Saratoga in the United States are some of them chalybeate, others sulphurous or iodinous; all of them being rich in carbonic acid gas. The Ballston saline spring near Saratoga has a very high proportion of carbonic acid. They are chiefly employed in cases of gout, rheumatism, scrofula, and abdominal plethora. (b) *Muriated Lithia Waters*, of which the chief contents are the chlorides of sodium and lithium. In gout they first aggravate the pain, but then give relief; and in periodic headache they have been found serviceable. (c) *Brines*, whose chief contents are a large amount of chloride of sodium, such as the spas of Droitwich in Worcestershire, Rehme in Westphalia, and Nauheim in Hesse. They are mostly employed for bathing, and are often of much service in scrofula, anæmia, rheumatism, certain forms of paralysis, and catarrh of the mucous membranes. (d) *Iodo-bromated Muriated Waters*, in which, besides a moderate quantity of chloride of sodium, the iodides and bromides of sodium and magnesium are contained in an appreciable quantity. The Kreuznach waters are used both for drinking and bathing, and are of service in tuberculous disease of the glands, in tuberculous ulcers, in chronic inflammation of the uterus and ovaries, &c. The waters of Hall, in Upper Austria, have a high reputation in cases of goitre.

(4) Earthy Waters, of which the chief contents are sulphate and carbonate of lime, as at Wildungen, Leuk, Bath, Lucca, and Pisa. The Wildungen water is a 'capital diuretic, and not only promotes the elimination of gravel and renal calculi, but, by its tonic action on the mucous membrane of the urinary passages, serves to prevent the formation of fresh concretions. It is also much used for chronic catarrh of the bladder, neuralgia of the urethra and neck of the bladder, dysuria, and incontinence of urine.' The baths of Leuk, in which many patients remain nine hours daily (viz. from 4 A.M. to 10 A.M., and from 2 P.M. to 5 P.M.), until an eruption appears, are chiefly

used in chronic skin diseases. The waters of Bath, Pisa, and Lucca, which are thermal, are useful in chronic skin diseases, gout, rheumatism, &c.

(5) Indifferent Thermal Waters, which usually contain a small amount of saline constituents. Of the spas of this class the most important are Gastein (95° to 118°), Teplitz (120°), Wildbad (96°), Warmbrunn (100°), Clifton (86°), and Buxton (82°). Their most striking effects are to stimulate the skin and excite the nervous system. They are especially used in chronic rheumatism and atonic gout; in diseases of the skin, such as prurigo, psoriasis, lichen; in neuralgia and weakness due to rheumatic and gouty exudations, to parturition, or to severe diseases, such as typhoid fever and diphtheria; in hysteria; and in general debility and wasting.

(6) Chalybeate Waters, which are divisible into (a) *Simple Acidulous Chalybeates*, whose chief contents are carbonic acid and bicarbonate of protoxide of iron; and (b) *Saline Acidulous Chalybeates*, whose chief contents are sulphate of soda and bicarbonate of protoxide of iron. The quantity of iron present is very small—from .08 to .15 in 1000 parts. Many of the chalybeate springs, especially in Germany, contain also much carbonic acid; carbonate, sulphate, and chloride of sodium is frequently present, and may help in the cure. Harrogate, Rippoldsau, Homburg, and the Putnam Spring at Saratoga are examples of chalybeate wells which are very seldom thermal. Strathpeffer has both chalybeate and sulphurous springs. Chalybeate waters are valuable in anæmia, enlargement of the spleen, and many female disorders.

(7) Sulphurous Waters, which contain sulphuretted hydrogen or metallic sulphides (sulphurets), or both; thermal as at Aix-la-Chapelle, Baden (near Vienna), Bâges, Eaux-Chaudes, and Bagnères de Luchon; cold as at those of Nenndorf and Harrogate. They are used externally and internally in chronic diseases of the skin, and are of service in swellings of the joints, in old gun-shot wounds, and in chronic gout and rheumatism. In chronic laryngeal and bronchial catarrh they frequently give relief. Mineral mud-baths are often a valuable auxiliary.

Mineral springs are now sometimes classified less by their mineral content than by their high index of radio-activity, due to substances of high instability and soon lost.

See Tichbourne and Prosser James, *Mineral Waters of Europe* (1883); Bradshaw's *Dictionary of Mineral Waters*; for U.S. and Canada, Walton (1875); Weber, *The Spas and Mineral Waters of Europe* (1896); the Report of a Committee on *The Climates and Baths of Great Britain* (2 vols. 1900-1902); Luke, *Spas and Health Resorts of the British Isles* (1919); and the works cited at HEALTH-RESORTS.

Miners' Worm. See ANKYLOSTOMIASIS.

Minerva, a Roman goddess, ultimately identified with the Greek Athena (q.v.). Her name may come from the same root as *mens* ('mind'); and the ancient Latin scholar and critic, Varro, regarded her as the impersonation of divine thought—the plan of the material universe of which Jupiter was the creator and Juno the representative. Hence all that goes on among men, all that constitutes the development of human destiny—itsself but the expression of the divine idea or intention—is under her care. She is the patroness of arts and trades, and was invoked alike by poets, painters, teachers, physicians, and all kinds of craftsmen. She also guides heroes in war; and, in fact, every wise idea, every bold act, and every useful design owes something to the high inspiration of this virgin goddess. Her oldest temple at Rome was that on the Capitol, but she had

another on the Aventine. Her festival was held in March, and lasted five days, 19th to 23d.

Minerva-press, a printing-office in Leadenhall Street, London, from which issued in the later 18th and early 19th century a long series of highly sentimental novels, with remarkably intricate plots and an ample measure of tribulation and tears before the happy dénouement was reached.

Mines, **MILITARY**, are underground passages, usually lined with planks termed *cases*, by means of which explosives are lodged in such a position as to destroy the enemy's works or to gain cover for lodgments from which the besieger may continue his advance. Before the invention of gunpowder, mines were constantly used to effect an entrance into a besieged place or to breach its walls by underpinning them with timber, which was then set on fire. Thus Alexander the Great breached the walls of Gaza. Cæsar found the Gauls so skilled in their use as to be able to arrest the progress of his own miners. Powder mines began to be largely used early in the 16th century. To meet attack by mining, *countermine*s behind the walls near their base, and then long galleries from them under the ditch with *transversals* and *listeners*, were added to the permanent fortifications of the 17th century. These enabled the besieged to ascertain the direction of the besieger's mining approach, and to destroy his galleries by timely explosions. Systems of countermine became very elaborate during the 18th century, radiating from the salients sometimes in several tiers; the length of the galleries for a single front in some cases amounted to 3 miles or more.

When the besieger can no longer advance by surface approaches he has recourse to mining, sinking a vertical *shaft* (about 4' x 2' inside measurement) or an *inclined gallery* (about 5' x 2'), generally from the third parallel, and from it working his way forwards. *Branch-galleries* (3' 6" x 2') are broken out wherever necessary, and specially constructed *frames* fitted throughout as the work progresses. In such a confined space only very small tools can be used, and only one man can work at the head of a gallery at one time, doing about 12 inches an hour. Small trucks and fan-blowers, or other ventilating appliances, are also necessary. At the head of the gallery a chamber is constructed to hold the charge, which is then *tamped*; that is to say, the gallery in rear is filled with earth for a distance greater than the length of the *line of least resistance*, or distance to the nearest surface, and fired by electricity, powder hose, or Bickford's fuse.

Mining tactics require very great coolness, judgment, and resolution, especially on the part of the besieged. He must from his listening galleries estimate the distance of the enemy and avoid exploding his countermine too soon or he will only injure his own galleries. If he ceases to hear the miner's truck running in the enemy's gallery, he will know that tamping has commenced, and that, if within range, the time has come to explode his countermine. The defender is restricted to small charges for fear of making craters in which the besieger can lodge, unless his countermine galleries are very deep, while the besieger can advantageously use very large ones. The chief point in the defender's favour is that he can prepare beforehand a network of galleries, and by using boring tools he can place charges some distance in advance of their heads. If the besieger has been unable to ascertain the disposition and extent of the countermine system by means of plans or spies, he will have to obtain this information by the tedious and uncertain process of pushing out trial galleries. He will then place heavily charged mines on a line as nearly

as possible parallel to the ends of the countermines, but not nearer than 14 yards, the distance at which work is audible to the enemy. These will be fired and lodgments formed in their craters, from which the same tactics are repeated; the countermines when broken into will be occupied, and thus ground be gradually gained, and the defender driven back step by step until the counterscarp is reached. The wall will be broken through by a mine, the ditch crossed, and the breach (if one has been formed by artillery fire) will be reached and occupied. Under the breach the defender will have placed mines which he will spring at the moment of assault. If no breach has been made, the escarp wall will be mined and a breach be formed by blowing it down.

The war experiences of the 19th and 20th centuries have taught nothing new as to military mining. This is not surprising, for the implements of underground warfare have not been altered, though in some respects they have been improved. Modern high explosives are not more than two to two and a quarter times more powerful than gunpowder, when the latter can be thoroughly well tamped, as is usually the case in military mines (see GUN-COTTON and DYNAMITE), and the only considerable advantage possessed by the modern sapper is in the use of electricity to fire his mines, to illuminate his galleries, and to work pumps for draining, and fans for ventilating them. These conduce to the greater certainty, comfort, and safety of his work, but do not alter the fundamental principles of mining, which have remained the same since the latter part of the 17th century. The later experiences have only confirmed those of the past, both as to how and when mining must be undertaken. At the siege of Port Arthur in 1904, during the Russo-Japanese war, a great deal of mining was done as part of the regular siege work which was undertaken by the Japanese, after they had lost some 1500 officers and 40,000 men killed, wounded, and missing, in numerous attempts to carry the defences by assault with the minimum of preparation. Similarly in the trench warfare of 1914-18 mining had to be resorted to very early, but later on a scale of wholly unprecedented magnitude. The case of the Messines Ridge may be regarded as classic. Here, on 7th June 1917, a series of mines, containing a total of about 450 tons of explosives, were exploded simultaneously over a front of over seven miles. This important position was then captured with the minimum of loss. Mining, instead of being an incidental, developed into a special service, employing some 25,000 officers and men. Every resource of science was utilised; geologists were employed to advise as to strata dealt with, especially as to the possible presence of water; while very important instrumental innovations were the *Geophone* and the *Seismomicrophone*, at the least doubling the ability of the ear to hear enemy movements underground. The *geophone* can be used actually to locate the position of such enemy activity (see *Military Mining* (1921) and *The Work of the Royal Engineers in the European War of 1914-19*).

Submarine mines are charges of from 200 lb. to 500 lb. of explosive material, usually gun-cotton (though tri-nitro-toluene is rapidly coming into favour), contained in sheet-iron cases, which are sunk at suitable depths in waters through which it is desired to prevent the passage of hostile ships. They are generally laid in several rows, more or less chequerwise. In laying mines two special difficulties are experienced—the first, in providing that they shall always maintain a suitable depth to be struck by hostile ships in spite of the drag due to currents and tides; the second, that they shall not shift their positions or break loose owing to

rough weather, and become menaces to the user as great as to his enemy.

Submarine mines are of two kinds. *Controlled* mines are fired, by observation from the shore, by means of an electric Fuse (q.v.) in the charge. Their advantages are that friendly vessels can pass over them in safety, while if they drift or break loose they can be easily rendered quite harmless. Their disadvantages are that they are practically useless for defensive purposes at night or in thick weather, need an elaborate electrical and telescopic installation for their control by day, and—except in positions singularly favourable for observation—cannot be employed more than about a mile from shore. *Uncontrolled* mines, which are most frequently used, are of two kinds—*mechanical* (fired by percussion mechanism) and *electro-mechanical* (fired by electric fuse), which, when once laid, will be exploded by a blow given by any ship, whether friend or foe. There are several variants of the uncontrolled mines mentioned above. One of them is connected with the shore by electric cable, and can be rendered at will either harmless or capable of explosion by a blow. It shares a disadvantage of the *controlled* mine in that it requires an elaborate electric installation.

Uncontrolled mines were used to an enormous extent in the Russo-Japanese war, and were responsible for the sinking or disablement of a great number of vessels—in many cases the combatants suffering from their own mines.

Similar mines, but to an enormously greater extent, were employed in the war of 1914-18, large portions of the North Sea being sown with mines by both belligerents, and the experiences with them were the same as in the Russo-Japanese war, but on a vaster scale, while their specific use as a protection against submarines greatly increased their importance. One governing principle would seem to emerge as the result of the latest experience, which is that, while submarine mines can be used with considerable effect by a weak naval power, they must in the long-run favour the stronger one, when operations take place in waters suitable for their use; for, unless protected by war-vessels, mine-fields can be swept without insuperable difficulty. Thus the use of the Straits of Dover by Britain almost without interruption during the whole of the war was rendered possible to a considerable extent by immense mine-fields, which the Germans were unable to sweep owing to their being guarded by superior force. *Sweeping* is carried out by dragging a cable stretched between two vessels, steaming parallel to each other, through the mine-field. Although vessels of shallow draught are used for the purpose, it is a hazardous operation, and the deeds of the mine-sweepers during the war rank high as examples of steady endurance and courage.

Mines, ROYAL SCHOOL OF. See KENSINGTON.

Minghetti, MARCO (1818-86), Cavour's successor, was born in Bologna, studied there, and travelled in France, Germany, and Great Britain. Pius IX. in 1846 made him, now a journalist, minister of Public Works. But under Austrian pressure the pope's reforming zeal was short-lived, and Minghetti entered the Sardinian army, and at Custozza earned a knighthood. An ardent student of economics, a free-trader, and a devoted friend of Cavour, in 1859-60 he was his secretary for foreign affairs. Successively minister of the Interior, of Finance, and premier (1863), he concluded with Napoleon the 'September Convention' in 1864. In 1868 he was Italian minister in London, and thereafter minister of Agriculture. At Rome in 1873-76 he was prime-minister for the

second time, and till his death was still the most prominent member of the Italian parliament. He wrote lectures and essays on Raphael and Dante, *Economia Pubblica* (1859), and *La Chiesa e lo Stato* (1878). See his *Ricordi* (1888).

Mingrelia. See GEORGIA, CAUCASUS.

Minho (Span. *Miño*, anc. *Minius*), a river of Spain and Portugal, rises in the north-east of Galicia, flows south-west through the Spanish provinces of Lugo and Orense, and, after forming the boundary between Portugal and Spain, falls into the Atlantic Ocean. Its total length is 174 miles, and it is navigable for small craft 25 miles above its mouth; a bar at the entrance prevents the passage of large vessels. Area of basin, 157,000 sq. m. Its chief tributary is the Sil, which joins it from the left.

Miniature-painting, or the painting of portraits on a small scale, originated in the practice of embellishing manuscript books (see ILLUMINATION OF MANUSCRIPTS). As the initial letters were written with red lead (Lat. *minium*), the art of illumination was expressed by the Low Latin verb *miniare*, and the term *miniatura* was applied to the small pictures introduced. After the invention of printing and engraving this delicate art entered on a new phase; copies in small dimensions of celebrated pictures came to be in considerable request, and, in particular, there arose such a demand for miniature-portraits that a miniature in popular language came to signify 'a very small portrait.' Soon after their introduction miniature-portraits were executed with very great skill in England. Holbein (c. 1495–1543) painted exquisite miniatures, and having settled in London, his works had great influence in calling forth native talent. The works of Nicholas Hilliard (born at Exeter 1547, died 1619) are justly held in high estimation. Isaac Oliver (1556–1617) was employed by Queen Elizabeth and most of the distinguished characters of the time; his works are remarkable for careful and elaborate execution; and his son, Peter Oliver (1601–47), achieved even a higher reputation. Thomas Flatman (1637–88) painted good miniatures. Samuel Cooper (born at London 1609, died 1672), who was with his brother Alexander a pupil of his uncle, John Hoskins, an artist of reputation (died 1664), carried miniature-painting to high excellence. Cromwell and Milton sat to him; he was employed by Charles II., and obtained the highest patronage at the courts of France and in Holland. Jean Petitot (1607–91) was the first to bring to perfection the art of enamelling as applied to portraiture. There are as many as fifty-eight examples of this great artist in the Jones Collection at the South Kensington Museum. Richard Cosway (1740–1821) was one of the most famous miniaturists of the 18th century. Robert Thorburn (1818–85) first made his name as a miniaturist, and many others might be mentioned; but the last famous miniature-painter was Sir William Ross (1794–1860), who lived to see his art superseded by photography. The number of his miniatures in existence is said to number over 2200. Of late years public interest in the work of the miniaturist has revived, and several exhibitions of miniatures have been held. Prices have advanced, and it is extremely difficult to obtain good examples. The works of Cosway are especially sought after. Photography may be said to have killed the art, although miniatures have continued to be painted; but enthusiasts hope from the interest now taken in historical specimens that the art may yet be revived. As to technical details, the early artists painted on vellum and used body-colours—i.e. colours mixed with white or other opaque pigments, and this practice was

continued till a comparatively late period, when thin leaves of ivory fixed on card-board with gum were substituted. Many of the old miniature-painters worked with oil-colours on small plates of copper or silver. After ivory was substituted for vellum transparent colours were employed on faces, hands, and other delicate portions of the picture, the opaque colours being only used in draperies and the like; but during the 19th century, in which the art was brought to the highest excellence, it became the practice to execute the entire work except the high lights in white drapery with transparent colours.

See Walpole's *Anecdotes*; G. C. Williamson, *Portrait Miniatures from Holbein to Ross* (1898); J. J. Foster, *British Miniature Painters and their Work* (1898); Russell, *Art of Miniature* (4th ed. 1873); Wagner, *Miniature Painting* (Phila. 1876); Dudley Heath, *Miniatures* (Connoisseurs' Library, 1905); J. W. Bradley, *Dictionary of Miniaturists* (3 vols. 1888–89); and J. L. Probert, *History of Miniature Art* (1889).

Minié, CLAUDE ÉTIENNE, inventor of the Minié rifle, was born in Paris in 1814, enlisted in the army as a private soldier, and quitted it as colonel in 1858. He devoted his principal thought to the perfecting of firearms, and in 1849 invented the Minié rifle (see RIFLE). In 1858 the khedive of Egypt appointed him director of a small-arms factory and musketry school in Cairo. He died in 1879.

Minims (*Fratres Minimi*, 'Least Brethren'—so called, in token of still greater humility, by contrast with the *Fratres Minores* or Lesser Brethren of St Francis of Assisi), an order of the Roman Catholic Church, founded by another St Francis, a native of Paula, a small town of Calabria, about the middle of the 15th century. See FRANCESCO DI PAULA.

Mining. In Great Britain a mine is legally distinguished from a quarry by the fact of it being illuminated artificially, the quarry being open to the sky. In its unrestricted sense, however, the art of mining comprehends the processes of getting from the earth (no matter by what methods) all useful minerals, whether solid (coal, stone, metallic ores, &c.), liquid (petroleum, brine), or gaseous (natural gas); it often also includes those surface operations which are essential to render the mineral acceptable to its purchaser (see ORE-DRESSING.)

The liquid and gaseous minerals are both searched for and obtained by means of bore-holes. Deposits of solid minerals are divided into beds, veins, and masses. Bedded deposits include cases apparently so dissimilar as coal-seams and the 'reefs' of quartzose rock worked for gold in the Johannesburg district. These are *stratified* rocks, i.e. they lie parallel to and conformable with other rocks above and below them. Beds were originally flat, but may now be found tilted at any angle, and twisted, torn, and folded in every conceivable way. Many minerals occur in beds, e.g. salt, oil shale, many ironstones, fireclay, rock-phosphate, gypsum, slate, gold in 'placers' or river-deposits, &c. In addition to the reefs of the Transvaal, there are many notable instances of the impregnation of beds by metallic minerals, e.g. copper pyrites in shale at Mansfeld, Germany, and in sandstone at Alderley, Cheshire; native copper (the metal itself) in sandstones, lavas, and conglomerates, Lake Superior; lead in sandstone, at Mechernich, Rhine Province.

A vein is a sheet-like deposit, intimately connected with a dislocation (fault) of the encompassing rocks. It is usually steep (60° to 90° inclination), and variable in constitution and width. A workable vein is commonly 2 to 6 feet wide, but, if sufficiently rich, one only a few inches in width may be wrought. At the Homestake Gold Mine,

Dakota, owing to a number of ore-bodies running together, a composite vein 500 feet has been formed. *Lode* and *vein* are often used as synonymous terms, but it is preferable to give to the former word a wider significance than to the latter; a lode may be said to be any unstratified sheet-like deposit containing valuable minerals, no matter what may have been its mode of origin. A mass conforms neither to the definition of a vein nor to that of a bed. It is usually very irregularly shaped, a typical case being that of the iron-ore masses of the Furness district, North Lancashire, which are huge pockets of hæmatite lying in limestone.

The mining of a bed differs in many respects from the mining of a lode. For instance, the commonest manner of approach of a bed is by a vertical shaft, which passes through barren strata until the bed is reached; on the other hand, a lode, lying at a high angle, is often reached from one or more drivages (inclined shafts), commencing on the *outcrop* of the lode (i.e. where the lode comes to the surface), and following the deposit to the dip. The latter system does not permit of rapid hoisting, it being only suitable for small outputs, while in the former hoisting (winding) at speeds which, in the middle of the shaft, may attain or exceed 60 miles an hour, is not uncommon. But it must be observed that in mining most beds (whether of coal, fireclay, &c., or of Witwatersrand gold-ore) the value per ton of the product is small, and profitable working depends upon raising large quantities. The need for a heavy output from a winding shaft, and of a steady and economical delivery of mineral to the bottom of that shaft, has led to great improvements in the operations of winding and underground mechanical haulage in coal and similar mines. The framework which supports the small mine-wagons (*tubs*, *trams*, or *hutches*) as they are being raised or lowered in a vertical shaft is known as a *cage*. It may have from one to six decks or platforms, two being the usual number; a large cage, fully loaded, may weigh 20 tons. To expedite the operation of changing loaded for empty tubs (or *vice versa*), the *simultaneous decking* of cages is frequently carried out at large collieries; when a multiple-decked cage reaches the top or bottom of a shaft, it comes to rest opposite as many platforms as there are decks, and the changing of all the decks simultaneously is carried out, sometimes by mechanical means, in a few seconds. The tubs which then remain on the platforms at pit-head or pit-bottom are dealt with while the cage is making its next journey. Colliery winding-shafts are generally provided with two cages. The largest shafts in the world are those of the Witwatersrand, in several of which six cages are in operation. These latter shafts are rectangular; those at most collieries are round, though many in Scotland are rectangular, and a few in Wales, Scotland, and America are oval in shape.

Owing to the risk of fire, the structure over a shaft-mouth (*headgear*, *poppit-frame*) is no longer being made of wood at British mines; steel lattice-work is the favourite type, but increasing numbers of these frames at home and abroad are being constructed of reinforced concrete—a material which is economical, rigid, fireproof, and not addicted to corrosion. Moreover, concrete lends itself to the formation of a shaft-housing, or covered heapstead, as a part of the same structure as the headgear. The tendency is to get under cover as much as possible of the surface arrangements (decking, tipping, picking, screening, &c.), and to eliminate wood, even for gantries.

The most striking difference between the up-to-date colliery and an old one is not so much the increase in scale of the undertaking as the greater

spaciousness and neatness of the former, both above and below ground; things are planned with a scientific directness, and often with an effective simplicity, which did not obtain in the 19th century; at every turn labour-saving devices and machinery are used; and electrical power is everywhere.

The typical metalliferous mine, working a lode, differs from a colliery in that it is dealing with a comparatively small output of a much greater value per ton. Due allowance being made for some exceptions, such factors as rapid winding and mechanical haulage do not need to be considered. In an unproved vein, an inclined shaft following the vein serves as an exploratory passage by which that very variable deposit may be examined. Subsequently, when the vein has been proved to be of a value to warrant the great expenditure, a vertical shaft or, alternatively, a straight inclined shaft situated altogether in the barren 'country' on one side or the other of the vein, may be sunk, and the vein approached from the shaft by *cross-cuts*. Cross-cuts are driven at vertical intervals, usually ranging from 60 to 250 feet. When a cross-cut reaches the vein a *level* is driven to the left hand and to the right hand, and in the vein itself. Vertical shafts are sunk to the deeper and flatter parts of Witwatersrand gold-reefs; when the reef is reached, one or more inclined shafts are set down in the reef or parallel to it. The hoisting-engines for the vertical shafts are at the surface; those for the inclined shafts are in this instance placed underground.

Metalliferous deposits are often found in hilly country. A vein outcropping on a mountain slope can be cheaply and conveniently reached by level drifts (*adits*) entering from the hillside, and shafts may not be required. Most of the seams of coal approachable by adits or day-levels have been exhausted in Britain; but coal-adits are common in the United States and elsewhere. Several anthracite mines in the western part of the South Wales basin and some oil-shale mines in Scotland are approached by 'slopes' or inclined shafts, but the method is uncommon elsewhere in British coalfields.

Collieries are provided with at least two shafts or other openings; one shaft is termed the *downcast*, as it conveys fresh air into the mine; the other the *upcast*, as it carries the vitiated air from the mine. Both these shafts have to be fitted with the means for raising or lowering persons, so that, should one be damaged, the other is available. A large mine, especially if there is much pumping of water to be done, may have three and even four shafts. A group of mines may be connected together underground; this method, though common on the Continent, is, however, infrequent in Britain. Though many mines raise coal from both upcast and downcast shafts, one shaft is often the chief or the only one at which mineral is wound. In Britain the principal winding-shaft is the downcast, and in the United States and Canada the upcast. The main reason for this difference of practice is to be sought in the less equable climate of the latter countries. Were they to wind at the downcast, much trouble—amounting sometimes to actual stoppage of the operations—would be experienced in winter owing to the formation of ice in that shaft. The upcast, on the other hand, is traversed by the warm air from the workings.

Circular shafts range from about 9 feet to 23 feet in diameter. Modern shafts for large undertakings are generally over 18 feet in diameter. The cost of sinking and equipping such a shaft may reach £150,000, while that figure will probably be exceeded if exceptional difficulties are encountered in sinking.

The deepest mine workings in the world are those of the Morro Velho Gold Mine, Brazil, which extend to over 6400 feet from the surface. Some of the deeper mines of the Lake Superior copper-bearing area are but little behind this figure. The record will be broken in the Transvaal, where the gold-reefs are to be worked at 7000 feet.

The deepest vertical shaft in Britain is that at the New Moss Colliery, near Manchester; it attains a depth of 2820 feet. Owing to the practice of following the seams to the dip from the shafts, the lowest parts of the workings are often considerably deeper than the shafts; for instance, at the Pendleton Colliery, near Manchester, the deepest mine in Britain, coal is being wrought at depths over 3500 feet, though the shaft is only about half that depth. The coal mines in the neighbourhood of Mons, Belgium, are exceptionally deep; the deepest of these—probably the deepest colliery in the world—is that called *Produits de Flénu*; the shaft is 3773 feet.

The depth to which mining can be carried out will be limited much more by the temperature of the rocks than by engineering difficulties. The salient factor in deep mining, then, is the natural rise of temperature of the rocks as the depth increases. The average rate of increase of temperature in Great Britain is about 1° F. for each 67 feet of depth, but wide local variations from that mean are known to exist. It is noteworthy that the very deep metalliferous mines to which reference is made above are all in districts of low *temperature gradient*, i.e. they are situated where temperature increases unusually slowly with depth. The temperature gradient at Morro Velho is 1° F. per 140 feet; at the Calumet and Hecla Mine, Lake Superior, 1° F. per 200 feet (approximately); while in the Johannesburg area it appears to be about 1° F. per 120 feet of depth. Notwithstanding this fortunate natural advantage, the lowest workings at Morro Velho proved to be excessively hot, until the air-temperature was reduced, first by improving the ventilation and then by installing refrigerating plant at a cost of £90,000. By means of the latter a part of the air entering the mine is artificially cooled.

The operation of searching for mineral deposits is called *prospecting*. Though the modern prospector takes advantage of the help afforded by geology and mineralogy, it has to be admitted that a great many famous deposits have been discovered by chance. Thus, the observation of pellets picked up by birds led to veins of gold-ore being found in Lower Hungary, while the rich silver mines of Potosi are said to have been discovered by an Indian goatherd, who, taking hold of a bush to prevent his falling, pulled it up by the roots, thereby disclosing an outcrop of silver ore. The great silver-lead deposits at Broken Hill, New South Wales, were found accidentally by a party who were looking for fresh pasturage for their sheep. The discovery which prefaced the famous Californian gold rush of 1849 was made by J. W. Marshall while cutting a small mill-race. Sometimes a valuable deposit has been found while searching for something else; for example, the great bed of rock-salt underlying the Cleveland district of North Yorkshire—a bed about 90 feet thick and extending over 20 square miles—was encountered while drilling for water. In some regions, and particularly in Africa, the prospector is on the look-out for old workings—a certain indication of mineral wealth. These ancient mines are widely spread, and occur in most unexpected places. The best known are the old gold workings in Rhodesia. Whatever race was responsible for them was highly skilled in the arts of mining and prospecting. That it was a foreign race, occupying the country for the sake of its

mineral wealth, and in face of the opposition of the natives, appears clear from the existence of a succession of ruins of fortified posts and towns, extending in a line—the trade-route of those days—from the mines to the eastern coast of Africa. Rhodesia may, indeed, be the Ophir ('Place of Gold') of the Old Testament. Ancient mines, regarding whose history we have no clue, occur in Nigeria and the Philippines; others, wrought by the Egyptians, are scattered about north-east Africa. The Egyptians, like the majority of the great races of antiquity, were skilful miners, and it is of interest that the oldest map in the world—a papyrus of about 1300 B.C., preserved at Turin—depicts the workings of gold-bearing veins in a mountainous district of the Arabian desert.

Coal, which occurs in definite and well-known geological positions, is searched for by *boring*. Bore-holes are also used by the metalliferous miner to prove the continuation of a lode, whether laterally or in depth, and to search for parallel veins—for veins not infrequently occur in sets or series, occupying fissures which are roughly parallel. Bore-holes can be drilled in any direction from the vertically down to the vertically up; the latter is useful now and then underground. For prospecting purposes, however, the down-right hole, drilled from the surface, is usual. There are many boring systems. In oil-mining two are principally used. The first and older (the *cable system*) consists in raising and dropping a string of tools, of which the bottommost is the bit or chisel. These tools or rods are attached together by conical screws; they are to give weight and guidance to the bit, while one of them (the *jars*) is useful in releasing a bit that has stuck in the hole. Originally the bit used in this system of boring was a cutting-chisel, but nowadays the narrow edge has been replaced by a very obtuse one, of which the faces lie at an angle of about 150°; the weight has been increased and the bit converted into a pounding rather than a cutting tool. The string of tools is operated by a cable extending, up the bore-hole, to a pulley at the top of a tall derrick (wood or steel) standing over the hole, and down again to a drum (the *bull-wheel*) upon which the excess is coiled. The cable is generally of manila for shallow holes and of steel for deep ones. The cable and tools can be withdrawn from the hole by setting the bull-wheel in rotation. When drilling, the cable is connected to one end of a horizontal oscillating beam (*walking beam*) by means of a combined feed-screw and grip called the *temper screw*; the motion of the beam is thus transmitted to the cable and tools. The cable system, which has been developed to a high degree of perfection in America, is the chief example of the *percussive* method of boring. The second method, which we owe to the oil-miner, is the *hydraulic rotary system*—a system in which a fish-tailed cutting-bit is rotated at the bottom of a column of hollow steel rods extending to the surface. When drilling is proceeding, a stream of thin mud is pumped down the hollow rods, and issues through an opening in the bit into the bottom of the hole; the stream then rises up the hole to the surface. The purpose of the mud-laden water is twofold. First, it removes and carries up the chippings cut by the bit, and, secondly, by penetrating into the walls of the bore-hole, the mud prevents an early collapse of the hole when drilling in soft material. The latter method is as yet unsurpassed for drilling in soft ground, and, under favourable conditions, a rate of progress often exceeding 100 feet per day is secured. About 45 horse-power is consumed by the hydraulic rotary drill and mud-pump. The cable system usually requires about 35 horse-power. All oil-wells are carefully lined with water-tight steel tubes. New

oil-wells now average about 2500 feet, but several holes exceeding 5000 feet have been drilled by the cable system.

The two boring methods described are not suitable in prospecting for coal or ores. For that purpose three rotary systems, the diamond, chilled-shot, and Davis-Calyx systems, are considerably employed. They resemble each other in that some form of cutting *crown* is rotated at the bottom of the hole by means of a column of hollow rods, down which water is pumped to keep the crown clear of the fine *débris* it creates. Each method, again, cuts a ring or annulus instead of chopping, as does a chisel, over the complete area of the circle. As the work proceeds, a column of rock, termed the *core*, rises within the hollow crown, exactly as a small cylinder of cork forms within a cork-borer. From time to time the core is broken off and brought to the surface for examination; these cores are invaluable in investigating a new district. The chief difference between the three methods lies in the character of the cutting-crown. The crown of the diamond drill consists of a hollow steel cylinder set with a number of diamonds (black stones or 'bort'), which are selected for the purpose because the diamond is the hardest of minerals. A diamond crown makes progress by the stones cutting into and abrading the rock. The chilled-shot crown is a simple steel cylinder; the abrasive material this time consists of numbers of hardened iron shot, $\frac{3}{16}$ th to $\frac{1}{4}$ th inch in diameter, which are fed down the hollow column of rods; being caught under the crown and carried round with it, the shot cuts its way forward. Chilled-shot drilling is cheaper than diamond drilling, and hard rocks can be bored through by means of it. The Davis-Calyx crown is furnished round its edge with teeth, and its action is more akin to cutting than to abrasion or scouring; it is unsuitable for drilling in hard ground, but it provides a cheap and rapid method of boring through softer rocks like shale. A simple type of toothed steel crown, flushed with thin mud instead of clean water, has come into use for oil-wells in California. It is of interest that in the earliest method of drilling yielding cores, a method invented by J. Ryan and employed before 1810, a steel tube armed with teeth was adopted. The deepest bore-hole put down in Britain was completed in 1907 at Cameron Bridge, Fife-shire. It was drilled by the diamond method, and reached a depth of 4535 feet. Starting at rock-head with a diameter of 7 $\frac{1}{2}$ inches, it finished, after nearly five years of work, with a diameter of 1 $\frac{1}{2}$ inch. The cores obtained from the bottommost portion of the hole were but little thicker than a common lead-pencil.

The great majority of mine-shafts are sunk by means of explosives, the *débris* being raised to the surface in buckets (*hoppits*, *kibbles*, *kettles*) holding from 1 to 5 tons; the water is raised by pumps suspended from ropes or chains; and the walls or sides are lined or cased with timber, brickwork, or concrete. Excessive inflows of water constitute the principal difficulty of sinking, and certain strata, like the magnesian limestone overlying portions of the coalfields of Yorkshire and Durham, have an evil reputation to the shaft-sinker because of the water they contain. Probably the greatest volume of water ever successfully dealt with in shaft-sinking by means of direct pumping was at the Horden Colliery, Co. Durham; the water came from the magnesian limestone, and at one time 10,000 gallons (45 tons) per minute were raised in one shaft by four suspended bucket-pumps, each of 30 inches diameter. After a water-bearing belt of rock has been sunk through, it is standard practice to dam it off by lining the shaft with a water-tight casing of cast-iron, known by

the name of *tubbing*. Tubbing is built in rings, each about 2 $\frac{1}{2}$ feet high, and each consisting of a number of segments cast with flanges and strengthening gussets. In the original or English system of tubbing the flanges are turned outwards, or away from the centre of the shaft, and the segments are tightened in position by driving large numbers of wooden wedges behind them, strips of wood being placed between the vertical and horizontal joints as a packing, which becomes water-tight under pressure. In the continental system, on the other hand, the flanges are internal, i.e. they project towards the centre of the shaft; strips of lead are laid in every joint, and the joints are made tight by the aid of bolts passing through the flanges. Among other technical advantages, continental tubbing can be built downwards from a hanging-ring, which is itself water-tight; tubbing so constructed is spoken of as *under-hung*. Sinking through watery strata has been facilitated and cheapened by the process known as *cementation*; it consists in forcing cement slurry through bore-holes drilled round the shaft and in advance of the sinking. Properly applied, the cement is most effectual in filling and sealing the water-channels in the strata. Cementation strengthens the ground round the shaft, and often renders tubbing unnecessary. It may also be employed when sinking or driving through loose, running sand. Another special process of sinking through watery ground or running sand is by freezing the water in an annulus, 4 or 6 feet thick, surrounding the section to be excavated. One or two rings of bore-holes are drilled round the shaft to the base of the watery stratum; they are completely lined with tubes and sealed at the bottoms; a smaller inner tube is then fitted within each bore-hole and reaching nearly to the bottom, thus allowing of a freezing liquid (usually a solution of calcium or magnesium chloride) to be circulated by a pump down the inner tube and up the outer one. The liquid is cooled at the surface by means of a refrigerating plant. When the ice barrier is complete, the shaft may be sunk without needing pumps and cast-iron tubbing built into place.

Previous to the introduction of blasting in mines, the cutting of galleries through hard rock was particularly laborious. It was done by means of three tools of great antiquity—the hammer, gad or wedge, and pick. The process of *fire-setting* was much resorted to in metalliferous mines in those days. It was probably an invention of ancient Egypt; at any rate, it was used by the Egyptians in their gold-mines. It consisted in building a fire of faggots against the face of rock to be broken down. The fire cracked and loosened the rock, rendering it amenable to attack by pick and wedge. Fire-setting actually remained in regular use in certain lead-mines of Germany until well into the 19th century—two hundred years after the introduction of blasting. Until comparatively recent times the sole explosive employed in blasting was common black powder. A good deal of powder is still utilised in quarries, such as slate quarries, where it is undesirable to shatter the rock, and in breaking down coal, where again it is necessary to obtain the mineral in as large pieces as possible. Its use in collieries is limited to those mines where there is negligible risk of the shots igniting firedamp or coal-dust, and even then is only allowed when made up into cartridges. The best powder-cartridge is 2 ounces in weight; it is made of gunpowder, compressed into the shape of a short cylinder, and is pierced axially for the admission of the fuse required to fire it. Ordinary fuse is of a diameter rather less than that of a lead pencil, and, like the pencil, it has a core running centrally

through it. The core is of fine black powder; it is protected by successive layers of jute tape, and, in the better kinds of fuse, by a water-proofing layer. It is made to burn at the rate of 2 feet per minute; hence 4 feet of fuse (a usual length in shot-firing) allows the miner two minutes to reach a place of safety after lighting the fuse. Gunpowder, or any other mining or quarrying explosive, is fired at the inner end of a *shot-hole* (generally from 2 to 6 feet in length), which is packed-up (*tamped*), after inserting the charge and fuse, with clay. The clay, known in this connection as *stemming*, is to prevent the charge blowing-out after the manner of a cannon; it is necessary to ensure that the explosive does useful work. In soft rocks, e.g. coal or shale, shot-holes are drilled by hand. A simple rotary type of drill is used; it automatically feeds forward $\frac{1}{8}$ inch for every complete revolution. Hand labour is still a good deal employed in drilling these holes in hard rock, such as that so generally encountered in metal-mines. The method in the latter case is percussive, the drill—an octagonal piece of steel provided at one end with a carefully-tempered chisel edge—being struck by a hammer. Between blows the drill is rotated to cause it to cut a hole of circular section. Immense improvement has of late years been effected in percussive rock-drills driven by compressed air, and their use is widespread to-day, particularly in metal-mines. They are divisible into two classes—i.e. the hammer-drill and the piston-drill. In the former, a rapidly reciprocating piston, working within a cylinder, strikes upon the end of the drill-steel; it acts, indeed, exactly as does the hammer in percussive hand-drilling. In the second type the drill-steel and piston are attached together, and therefore reciprocate together. In both types means are provided for the automatic rotation of the drill-steel. Many drills of either class are supported, when in use, upon a steel bar or stand rigidly set between roof and floor, or horizontally between the walls of the working place; the pistons of such drills are generally from $2\frac{1}{4}$ to $3\frac{1}{4}$ inches in diameter, though lighter ones are employed in metal-mine *stopes* (working places). The most familiar type of hammer-drill is the *jack-hammer*, a light form having a piston diameter of about $1\frac{1}{2}$ inch; it is generally supported by hand, but special stands are now provided to facilitate the drilling of upward-trending holes by the jack-hammer. Heavier drills usually run at 180 to 250 double-strokes per minute, but the jack-hammer strikes about 2500 times per minute. Compressed air for drilling purposes is supplied at pressures between 40 and 100 lb. per square inch. Higher pressures imply smaller drills for the same duty; the advantage is, however, gained at the expense of a heavier cost in repairs. A lengthy and drastic trial of light stoping drills was carried out in 1908 at Johannesburg. The two drills which shared the first prize in the competition (Holman $2\frac{1}{4}$ inches and Siskol drills) respectively drilled, in the very hard Rand quartz-ore, at the rates of 0.742 and 0.818 inch per minute, the time being taken as the whole period the drills were set up, including stoppages. The cost for the two drills was 9.77d. and 9.90d. respectively per foot drilled.

The discovery of nitro-glycerine by Sobrero in 1847, followed twenty years later by Nobel's invention of the first practical nitro-glycerine explosive (dynamite), marks a new era in mining—the era of the high explosive. Technically, a high explosive is one requiring to be fired by *detonation*. Most of the high explosives are much more powerful than gunpowder, and have a shattering rather than a rending action. Some, however, are more gentle in their effect, having been intended for breaking

down coal. An immense number of high explosives is now known; the most popular, e.g. *blasting gelatine*, *gelignite*, and *dynamite*, have nitro-glycerine as the explosive base; others, e.g., *ammonal*, have nitrate of ammonia as the main ingredient. To explode a charge of high explosive, a *detonator* is fired in the charge. A detonator is a copper cylinder closed at one end and resembling a very long percussion cap. The cylinder is almost half full of fulminate of mercury. No. 6 detonator—one of the commonest sizes—contains 1 gram of fulminate. The detonator is attached to a powder-fuse; it is then inserted in the charge; the cartridge, so prepared, is pushed to the back of the shot-hole; the hole is stemmed with clay, and the fuse lighted. The firing of the fulminate explodes the charge. *Electric detonators* are used on a large scale in British coal-mines; they are fired by means of a hand-worked magneto (*shot-firing machine*) and a length of double-core cable. Electric-firing is safer and surer than firing by means of the powder-fuse. It is compulsory in certain classes of mines and in pits in process of being sunk. A special group of explosives, known as *permitted explosives*, has come into being to satisfy the coal-miner's need for explosives which do not produce flame. These are rigorously tested before they are placed on the 'permitted list,' and their use is compulsory in any part of a mine where there is the least risk of an explosion of coal-dust or firedamp.

Relatively, metal-mines are much greater users of explosives than coal-mines. The copper-mines of the Butte district, Montana, between them use 7 million pounds weight of dynamite per annum. When a porous cartridge of carbonaceous material—e.g. charcoal—is saturated with liquid oxygen it forms a powerful explosive. Liquid oxygen explosives were used considerably in Germany during the Great War for mining and quarrying, though they are unsuitable for gassy collieries. The liquid oxygen (temperature -185°C.) is carried in double-walled vacuum vessels, resembling thermos flasks, but made of metal or porcelain.

However they be hedged in by regulations, explosives will always be dangerous, and the colliery manager studies to reduce their use to a minimum. The pressure of the roof may, in favourable circumstances, be directed to the breaking down of coal, and by a proper control of roof-pressure a few collieries do not require to fire shots in coal from one year-end to the other. Wedges are also applied. Many attempts to get a substitute for an explosive charge have been made. Hydraulic pressure and the expansive force generated when lime is wetted have, for example, found transitory favour, but these means have been given up for technical reasons.

Before coal is broken down by explosives, or by the roof pressure or other means, it is *undercut*. An undercut is a slot cut in the lowest part of the bed. Undercutting or holing constitutes the miner's hardest task; in doing it, he lies on his side or sits in a crouching position, a light pick (*holing pick*) being the tool employed. The use of *coal-cutting machines* (which are principally holing machines) has developed greatly of late years, and Britain bids fair to rival America in their application. They are driven by compressed air or by electricity. They make a neat, low slot in the coal, or in fireclay below the coal. The average depth of a machine-cut is about 3 feet 9 inches, but some machines reach under to a depth of 6 feet, and very exceptionally to 7 feet. The machines, which draw themselves along the 'face' by means of a steel rope or chain, generally operate during the afternoon and night shifts, the coal being broken down and removed during the morning

shift. They commonly cut a distance of 120 or 150 yards per day, but this distance does not represent their full capacity. With the majority of these machines the actual undercutting is done by means of an endless chain provided with detachable teeth or 'picks'; the chain projects under the coal, and is driven by gearing from the engine or motor. The cutting implement in another type is a large, flat, rotating disc furnished with teeth round its periphery; while a third variety undercuts by means of a straight, tapered bar of nickel steel fitted with a larger number of small teeth, and made to revolve rapidly. Certain other machines are designed to undercut in narrow places—i.e. in roads 12 or 15 feet wide driven in solid coal; while yet another form, only employed in thick seams, bores out a complete road, circular in section, and 5 feet 6 inches in diameter.

The actual methods of working coal, though subject to almost endless variation in details, are amenable to classification under two heads, viz. *bord-and-pillar*—also known as *pillar-and-stall*, *stoop-and-room* (Scotland), *pillar-and-entry* (America)—and *long-wall*. The former is the commoner in America, but the latter is preferred in Britain. In *bord-and-pillar* working a section of the seam is first cut up into pillars by driving roads at right angles to each other. The pillars are either square or rectangular, with sides varying between 15 and 80 yards in length. The pillars are then removed by working them off in slices, and the roof is allowed to collapse. The *bord-and-pillar* method still proves the cheaper if the seam is thick, the coal free from streaks or layers of dirt, and the roof strong. On the other hand, the *long-wall* system is preferable for thin seams or for those yielding a lot of rubbish in working. *Long-wall* consists in removing the coal in a single operation by working it on long 'faces' or 'walls.' As a face is advanced and the coal removed, the roof subsides and breaks over the area (the *gob* or *waste*) left behind. Roads, supported at the two sides by thick walls of stone and rubbish (*pack-walls*), are maintained through the waste for access to the faces and for the removal of coal. The *long-wall* system especially lends itself to undercutting by machines. It also permits of the installation, at machine-cut or other faces, of *conveyers* to carry the coal wrought at the faces to points where the conveyers discharge into mine trams or 'tubs.' The *long-wall face conveyor* is a familiar machine in British mines, and has effected a saving in working costs, and an increased production per person employed. At the Newbattle Colliery, Midlothian, the whole of the coal is cut by machinery, and is transported along the faces to the road ends by conveyers.

It has been described how, in metal-mines operating on a steep lode, levels are driven in the lode at vertical intervals ranging between 60 and 250 feet. The levels are connected by a large number of passages running to the full rise or dip of the lode. If these passages are driven upwards they are called *rises* (*raises*, America); if driven downwards they are known as *winzes*. The passages in question serve first as a means of exploring the lode between adjacent levels; secondly, as a means of access to, and of ventilation of, working places which, later on, are wrought in connection with them; thirdly, they become useful in the discharge of ore and water from those working places. By a series of levels and winzes (or rises) then the lode is divided up into large rectangular blocks. The extraction of these blocks, or of such portions as are sufficiently rich, is called *stopping*. A stope may be carried upwards (*overhand stope*) from a level, taking out the ore as it proceeds, or it may be carried downwards (*underhand stope*).

Though both modes of stopping are practised, the former is the commoner. If the lode is thin, a good deal of waste rock will have to be broken down in the operation of stopping; the waste is left behind, and serves a useful purpose in supporting the sides of the stope. When working a wider deposit no such supply of waste is forthcoming from the stope itself, and filling material is often imported from other parts of the mine or brought down from the surface.

No operation in mining consumes so much power as that of pumping water. Pumping by wooden or iron rods descending the shaft is still practised in both coal and metal mines. The rods, which are given a slow up-and-down motion by a surface engine, operate a pump, or, in deep shafts, a series of pumps, situated in the shaft. The usual method, however, now consists in placing the pumps underground and driving them electrically. Many reciprocating underground pumps are used; but the mine pump *par excellence* is the turbine pump. It consists of a number of wheel-like *impellers* provided with vanes or blades. Several of these impellers are carried on a single shaft. The water enters at the centre of the first, is thrown out centrifugally by the blades, is guided to enter at the centre of the second wheel, and so on, being finally discharged into the pipe conveying the water up the shaft. Turbine pumps are suitable for an electric drive; they can deal with large volumes and can raise water to a height which may exceed 1000 feet.

The health and efficiency of the underground worker depends more upon effectual ventilation than upon any other factor. Primarily, mine ventilation is needed to remove injurious gases from the working places; in addition, deep mines are largely dependent upon a copious ventilation for the reduction of temperature and of the percentage of watery vapour in the air. In the early days of mining, mines were ventilated altogether by *natural ventilation*, so called. Natural ventilation is caused by a difference in the temperatures of the air underground and at the surface. Though natural ventilation is often yet a potent influence, especially in deep hot mines, it is never nowadays allowed to act alone in coal mines, though great numbers of metalliferous mines depend upon it still. Ventilating fans are now universally used at collieries as the main means of creating a ventilating current. They are used in all sizes and capacities, from those yielding 1000 or 1500 cubic feet per minute (installed below ground for such a purpose as the airing of an 'end'), to machines consuming many hundreds of horse-power and delivering, in exceptional cases, 400,000 or 500,000 cubic feet of air per minute.

Large fans, or primary ventilators, are installed at the surface; in this country the majority of them are suction fans, connected with the upcast shaft. In America, on the other hand, the greater proportion are forcing fans, and connected with the downcast shaft.

The efflux of firedamp in the roads and workings imposes upon the coal-miner an imperative need for efficient ventilation; and it may be of note that in some gassy mines the weight of air drawn through the workings is six or eight times as much as the weight of coal raised from the mine per day. In many districts the metal-miner has begun to recognise that an efficient ventilation is as important to him as to the coal-miner. Though he seldom has firedamp as a stimulant, he has other dangerous gases to cope with, especially the products of explosives which he employs on so large a scale. He is learning that the economic loss, through the efficiency of workers being reduced by bad ventilation, is greater than the cost of good ventilation.

Ventilation by large exhausting fans, following coal-mining practice, is common in the gold-mines of the Transvaal. In the mines of the great copper region of Butte, Montana, hundreds of fans (mostly small ones placed underground) are in use, and the volume of air caused to circulate by mechanical means is rapidly increasing.

The conveyance of steam underground being almost obsolete, the two principal varieties of power employed in mines are electricity and compressed air. Though the usual practice is to generate the power required at each individual mine, the tendency is to a greater and greater extent to centralise power-plant, and to supply groups of mines from a single electric power-station. In other cases mines purchase their electric power from a supply company or municipality. The aggregate horse-power of electric motors at British mines amounted in 1922 to over 1,200,000. By reason of the great efficiency of transmission, alternating current is preferred to direct current electricity. Electric power is used for a wide variety of purposes, e.g. pumping, haulage, winding, coal-cutting, lighting, and fan-driving. Compressed air is uneconomical to transmit more than a short distance from the compressor, but it has advantages which cause it to be retained. First, it is safer than electricity to use in places where there is danger of ignitions of coal-dust or firedamp; secondly, it is much more suitable for operating rock-drills.

For the history of the miner's safety-lamp, see **SAFETY-LAMP**. The modern safety-lamp is of two classes: the *flame lamp* and the *electric lamp*. The flame lamp burns oil or benzine; the wick is generally flat and $\frac{1}{2}$ inch broad. Fig. 1 shows, in half-sectional elevation, the well-known 'Marsaut' type, with two concentric gauzes, D and C; a

Fig. 1. — Double-gauze Marsaut Safety-lamp.

Fig. 2. — An Electric Safety-lamp.

riveted sheet-steel bonnet, A; a stout glass, G; oil-vessel, E; wick-tube, F; and pricker for adjusting the flame, H. Fresh air enters the lamp through holes under the base of the Bonnet, in the manner shown by the arrow, B. To lock the lamp, a lead rivet is put through the hole, J, and squeezed end-wise by special nippers; it can only be removed by cutting it, so that opening the lamp by an unauthorised person is detected when the lamp is

333

returned to the lamp-cabin at the end of the shift. Should the lamp be assembled without its gauzes, the fact cannot pass unnoticed, for in that condition the glass cannot be tightened. A safety-lamp is examined by a person appointed for the purpose before the user passes into the mine. Fig. 2 illustrates a familiar form of electric hand-lamp. A is the small incandescent glow-lamp; B, a strong dome-shaped cover-glass; D, the 2-volt accumulator; C, one of the terminals of the accumulator, pressed by a spring against an insulated plate, which in turn is connected to one end of the lamp-filament (the other terminal is similarly connected); E, the stout stamped-steel case holding the battery; while F is a magnetic lock—a secure form which is much used for all classes of safety-lamp. The locking-catch engages as soon as the lamp-top is attached, and can only be disengaged by means of a strong electro-magnet, which draws up the plunger, F. Electric head-lamps are used on an enormous scale in America, and are coming into favour in Britain. They consist of a battery slung to the man's belt, a well-protected incandescent lamp carried in front of the cap, and a protected flexible cable connecting the two. They give a man the free use of both hands.

The Hailwood combustion-tube lamp is an important type. It is a double-gauze flame lamp, with an inner metal chimney. The chimney supports, at its lower end, a short glass surrounding the flame. The additional glass and chimney have the same effect as the glass chimney of an ordinary oil table-lamp; it improves combustion by keeping apart the fresh air passing to the flame and the vitiated air passing from it. The 'combustion tube' improves the illuminating power by at least 40 per cent. All safety-lamps are subjected to stringent official tests as to their security in the presence of gas and as to their mechanical strength before being approved for use in Britain. Flame lamps must give at least 0.3 candle-power for a period of 10 hours; most modern kinds give about 1 candle-power, while a few exceed that figure. Electric hand-lamps must give at least 1 candle-power. The standard gauze for flame safety-lamps is that introduced by Davy; it is of charcoal iron wire, of 28 S.W.G. (0.0148-inch diameter), and has 28 apertures per linear inch. Official tests have, however, shown that the same degree of safety is obtained, together with a considerable improvement in illuminating power, by adopting more open gauze, and a gauze with 20 meshes to the linear inch made of 27 S.W.G. (0.0164-inch diameter) wire is recommended.

The majority of flame lamps are fitted with a device which enables them to be lighted electrically after the lamp has been assembled and locked. As electric lamps do not give any indication of the presence of harmful gas, it is necessary to employ along with them a few flame lamps to serve as gas-indicators.

Of the 584,761 flame safety-lamps used in British mines in 1923, 402,682 were of the Marsaut type, and 176,344 of the combustion-tube type. In that year 327,929 electric safety-lamps were employed.

A recent development of lighting at coal-faces is by means of ordinary incandescent electric lamps, of either the exhausted or gas-filled type, current being supplied by means of flexible cables from the power-system. The improvement in illumination is enormous, and to the miner a better light means increased safety, reduced eye-strain, and a higher output.

The two agents responsible for explosions in coal-mines are firedamp and coal-dust. Firedamp is principally marsh-gas or methane. Marsh-gas mixed with air is explosive between the limits 5.4 and 14.3 per cent. The most violent explosion

occurs when 9·6 per cent. of the gas is present. It is necessary for safety to detect much less than 5·4 per cent. In a pit using safety-lamps, men are not allowed to work in air containing more than 2·5 per cent., while in those mines using naked lights the equivalent figure is 1·25 per cent. Because of its low density, firedamp tends to lurk in cavities in the roof. The flame safety-lamp reveals the presence of the gas. If the lamp be slowly raised into such a cavity the flame will draw out (*spire*) if firedamp be present. To ascertain the proportion of the gas occurring, say, at a face of work, the flame is pulled down until it loses its luminosity; if firedamp be present, a faint blue halo (*blue cap*) appears over the flame. The size of the halo indicates, to the skilled eye, the percentage of inflammable gas. Fine dry coal-dust is very explosive. It may be fired by a shot or by the explosion of a firedamp accumulation. Almost all large-scale colliery explosions are due to coal-dust. The greatest dust explosion in the history of mining occurred in 1906 at the Courrières mine, near Lens, North France; 1100 men and boys lost their lives, and four pits (connected underground) were devastated. The biggest disaster of the kind in British annals was in 1913 at Senghenydd Colliery, South Wales; 439 persons were killed. The most efficacious method of preventing dust explosions is periodically to cover the roof, walls, and floor of dusty roads with fine inert stone-dust (e.g. ground-shale or limestone) so that at all times the dangerous coal-dust is diluted with at least an equal weight of inert dust. This operation, known as *stone-dusting*, is much practised.

Mining is, and must always remain, a dangerous industry. It is, however, satisfactory to report that in the matter of safety a steady improvement is evident over the period during which accurate statistics have been kept. The average annual death-rate from accidents (surface and underground) at British coal-mines was, per 1000 persons engaged, 2·24 for the decennial period 1873-82, 1·39 for that of 1893-1902, and 1·15 for 1913-22. When the fatal accidents are analysed, it becomes evident that the most marked improvement has been in reference to deaths from explosions, which annually accounted for 0·65 per 1000 in 1873-82, but only 0·10 in 1913-22. The chief causes of accident underground are falls of roof or coal, and in this connection very little improvement is discernible since 1893. The number of non-fatal accidents occurring yearly from falls of ground is large. In 1922 over 63,000 persons were disabled for more than seven days owing to this cause alone.

Mines of coal, stratified ironstone, fireclay, and oil-shale are regulated by the Coal Mines Act of 1911, and by a number of short supplementary acts concerning safety measures and hours of labour; in addition there are numerous ancillary regulations dealing with safety-lamps, rescue apparatus, explosives, electricity in mines, stone-dusting, conditions for granting certificates of competency for officials, &c. Metalliferous mines in Britain (including under that designation all mines not under the Coal Mines Act) are under the control of the Metalliferous Mines Regulation Acts of 1872 and 1875, while quarries over 20 feet deep are controlled by the Quarries Act of 1894.

The miner is liable to certain special diseases, of which the most important is miners' consumption or *fibroid phthisis*. The disease is caused by constantly breathing extremely fine particles of gritty dust, produced when drilling or shot-firing or handling quartz-ore, sandstone, granite, or ganister. Respirators are little or no use as a preventive, since the particles most effectual in setting up the disease are of the order of $\frac{1}{1000}$ inch in diameter, and no respirator permitting breathing can stop

such minute pieces. The best precaution is thoroughly to wet any quartzose material before handling, and to direct a copious stream of water into, or on the mouth of, a shot-hole which is being drilled. Miners' anæmia (*Ankylostomiasis*; q.v.) is caused by a parasitic worm which clings—sometimes in enormous numbers—to the inner lining of the intestines. Though endemic in South Europe and other warm countries, the ailment has fortunately not made headway in Britain or North America. An outbreak of the disease in Cornwall early in the century was, thanks to prompt precautionary and remedial measures, quickly stamped out. It never spread in our coal-mines, though it was at one time a scourge in the collieries of Germany and Poland. Miners' *nystagmus* is an involuntary oscillation of the eyeballs, resulting from their overstrain. It is considered to be the result of an insufficient illumination, though other factors may eventually be found to have an influence. *Nystagmus* is rapidly increasing in coal-mines; compensation was paid in respect of over 4000 new cases occurring in 1922.

In England and Ireland the crown has the right to all mines of gold and silver; but where these metals are found in mines of tin, copper, iron, or other base metal, then the crown has only the right to take the ore at a price fixed by statute. In Scotland gold-mines belong to the crown without limitation, and silver-mines when three-halfpence of silver can be extracted from the pound of lead. As a general rule, in the United States as well as in Britain, whoever is the owner of freehold land has a right to all the mines underneath the surface, for his absolute ownership extends to the centre of the earth; but under special grants and contracts it is not uncommon for one person to be owner of the surface of the land and another to be owner of the mines beneath; or several persons may be owners of different kinds of mines lying one above the other in the different strata. On the public lands of the United States, a title or license may be obtained by any citizen from the general land office at Washington, at the rate of \$5 per acre of surface pre-empted; no royalty is paid, but the claim must be worked in accordance both with local regulations and with the general mining laws, which prescribe as one condition the performance of a certain amount of work annually. If this condition is not fulfilled, the mine may be 'denounced,' and any other person secure the claim.

BIBLIOGRAPHY.—The literature of mining is very extensive, but the following may be cited as useful works of reference: C. le Neve Foster, *Ore and Stone Mining* (7th ed.); H. W. Hughes, *Text-book of Coal-mining* (5th ed.); B. H. Brough and H. Deans, *Mine Surveying* (15th ed.); A. H. Cox, *Prospecting for Minerals* (6th ed.); R. Peele, *Mining Engineers' Handbook*; W. S. Boulton, *Practical Coal-mining*; W. R. Crane, *Ore-mining Methods*; H. F. Bulman, *Coal-mining and The Coal-miner*; R. A. S. Redmayne and G. Stone, *Ownership and Valuation of Mineral Property*. Reference should also be made to the *Transactions* of the Institution of Mining Engineers, Institution of Mining and Metallurgy, and other societies, to the technical journals, and to the *Annual Report* of the Secretary for Mines.

Minister, a public functionary who has the chief direction of any department in a state, the ministry being the body of ministers to whom the sovereign or chief-magistrate commits the executive government (see CABINET, PARLIAMENT, TREASURY).—Minister is also a term for a delegate or representative of a sovereign at a foreign court (see AMBASSADOR).—Christian preachers and priests are ministers of the word of God or of Jesus Christ in Catholic usage. The word minister was adopted by French-speaking Protestants for their clergy, and was formerly so used by Anglicans for theirs, as it still is by Presbyterians and many Nonconformists.

Minium, or RED LEAD. See LEAD.

Miniver. See FURS.

Mink (*Putorius*), a name applied to several carnivores very closely allied to weasel, polecat, and stoat or ermine, and with essentially similar characteristics. The body measures from 12 to 18 inches in length, not including the bushy tail. The colour of the valuable fur is chestnut-brown. The Siberian Vison (*P. sibiricus*), the European Vison (*P. lutreola*), and the American Mink proper (*P. vison*) are very nearly related, if indeed they are not simply varieties of one circumpolar species. They all live by rivers and lakes, in which they swim and dive, feeding chiefly on fishes, frogs, mussels, and the like; though not refusing any small mammals which come in their way. They are keen-scented, bold, and persistent, but are readily tamed when caught young. See FURS.

Minkopis, a name sometimes given to the negro inhabitants of the Andaman Islands (q.v.).

Minneapolis, the largest city of Minnesota, adjoins the capital, St Paul, and stands on both sides of the Mississippi, here crossed by many bridges—the Franklin Avenue bridge notable for its great concrete arch. The Falls of St Anthony, with a perpendicular descent of 16 feet, afford a water-power which has been a chief source of the city's prosperity. The streets are wide and handsome, and there are beautiful public parks. Among the most notable buildings are the Masonic Temple, the Post-office, the Bank of Commerce, the Auditorium, the Chamber of Commerce, and the Lumber Exchange. The court-house and town-hall, completed in 1902, is a magnificent building. There are twenty public parks. The public and private schools are numerous, with many secondary and special institutions; while the state university here has some 650 professors and lecturers and 12,000 students of both sexes. The lumber and flour mills of Minneapolis are among the largest in the country, the city being the greatest primary wheat market of the world. In the flour-mills stones were early discarded, the Hungarian or 'roller' process (see MILL) being employed. Linseed-oil and oil-cake are made. The railway facilities of Minneapolis are very great, and the growth of the city has been remarkably rapid. Pop. (1870) 13,066; (1880) 46,887; (1890) 164,738; (1900) 202,718; (1910) 301,408; (1920) 380,582.—Five miles SE. are the Falls of Minnehaha ('Laughing Water'), celebrated in Longfellow's *Hiawatha*.

Minnesinger, the collective name given to the lyric poets of Germany who flourished during a period marked approximately by the years 1170 and 1250. For the most part the singers were of knightly birth and belonged to the inferior nobility, though men of the very highest rank, reigning princes and even emperors, wrote these lyric effusions, and a few were of burgher birth. They get their name from the principal theme that inspired them, *minne* = 'love,' the love of fair women. Thus they were so far akin to the troubadours of Provence and France. The movement, however, though it certainly received suggestions from the singers beyond the Rhine, was essentially of native origin. The difference between the two schools is most clearly seen in the spirit of their work. The German singers wrote of love in a more refined and delicate spirit, and with a greater reverence for woman, than the troubadours. The best of them treated of the inner life of the soul, the feelings and emotions of the heart, rather than of the gallantries and adventures of a sensual love; they move in the world of imagination and idealism, shunning the real world and its gross pleasures; the shy, speechless, reverent attitude of ingenuous youth that characterised

them was closely akin to the reverent homage paid to the purest and holiest of women, the Virgin Mother of Christ. Yet they did not altogether lose touch of the world. They loved to sing the praises of nature, especially of spring, the perennial inspirer of poets' hearts and tongues. Often, too, there is a decided strain of sadness and melancholy, always touches of true naïveté, and frequently of arch humour, and on occasion the sterner note of moral indignation and contempt of the follies and vices of the time. Thus, the best of the minnesinger, like Walther von der Vogelweide, the most illustrious of them all, Heinrich von Ofterdingen, Wolfram von Eschenbach, Hartmann von Ane, Gottfried von Strassburg, Heinrich von Veldeke (the earliest), and others, were distinguished on the one hand from the poets of the monasteries, who celebrated the deeds of martyr and saint, and on the other hand from the wandering gleemen, whose subjects were suited to the coarse and ignorant peasantry who formed their usual audiences. But it is not in subject only, and their spirit of treating it, that the minnesinger differ from all their contemporaries; they also paid great attention to poetical form, striving after melodious and sonorous language, regularity of verse-structure, and smoothness and correctness of versification, in all which they attained a high degree of skill. Their art was, however, wider than the poet's at the present day: they not only wrote the text but composed the air to which the text was to be sung, for all their lyrics were written with the express purpose of being sung to the accompaniment of viol or harp. One class alone was exempted from musical accompaniment—viz. short didactic or sententious poems called *sprüche* = 'sayings,' which were recited. As it was incumbent upon a 'singer' to invent his own combination of text and melody, and was considered dishonourable for him to appropriate those of his predecessors or contemporaries, their poems are remarkable for a great variety of forms, poetic and musical. This in course of time, when the fresh inspiration of the movement began to wane, was the fruitful cause of much artificial writing, and eventually of the decay of the art. But there were still deeper causes of decay inherent in it. The less refined of the 'singers' were unable to keep the levels of exalted sentiment of their superiors, and degenerated into false sentimentality, lifeless conventionality, and above all a gross and vulgar sensualism. The minnesinger wrote principally in the Swabian dialect of Middle High German. Their use of this language was due to the great encouragement they received from the Hohenstaufen emperors. Next to these rulers their chief patrons were the dukes of Austria, and especially Hermann of Thuringia, at whose court of Eisenach the semi-mythical Wartburgkrieg occurred (c. 1207). This was a poetical contest between the chief minnesinger as to the merits of the patrons of the art: Heinrich of Ofterdingen was outsung by Walther von der Vogelweide, and Heinrich's ally, the magician Klingsor of Hungary, by Wolfram von Eschenbach.

When men of knightly birth began to neglect the writing of lyric poetry, and the minnesinger were no longer held in honour in the halls of the great, the art took refuge with the burghers and craftsmen of the cities. But with the exception of Hans Sachs of Nürnberg, those *Meistersinger*, as they called themselves, possessed little real poetic feeling. They formed themselves into guilds and wrote poems, as they plied their trade, by purely mechanical rules, and bound themselves by a multitude of puerile restrictions and pedantic regulations. Their subjects were painfully commonplace, and their treatment destitute of all artistic feeling. Yet these singers' guilds flourished from the 13th to

the 16th century; the last, at Ulm, was dissolved in 1839. Wagner's *Meistersinger* perpetuates their memory.

The lyrics of 160 Minnesinger were published by Von der Hagen in 1838 (4 vols.); and selections from 97 (of the 300 or more of whom specimens survive) by Karl Bartsch (1901). Modern versions have been made by Tieck (1803), Simrock (1857), and others; and English translations by Nicholson in *Old German Love Songs* (1906), and Jethro Bithell in *The Minnesingers* (1909). See Lyon, *Minne- und Meister-sang* (1882); Lachmann and Haupt, *Des Minnesangs Frühling* (ed. by Vogt, 1882); F. Pfaff, *Der Minnesang* (1892).

Minnesota, one of the north-central states of the American Union, ranking seventeenth amongst the states in respect of population. With an Indian name meaning 'sky-tinted water,' it lies around the headwaters of the Mississippi River, and extends from 43° 30' to 49° N. lat., and from 91° to 97° W. long. It is bounded on the N. by Manitoba and Ontario, E. by Lake Superior and Wisconsin, S. by Iowa, and W. by North and South Dakota. Its area is 84,682 sq. m., or nearly as large as Great Britain. In Minnesota are the remote sources of the great rivers Mississippi, Red River of the North, and St Lawrence, whose waters, flowing in different directions, reach respectively the Gulf of Mexico, Hudson Bay, and the Atlantic Ocean. Within the state the Minnesota River is the largest tributary of the Mississippi. Between the St Croix River and Red River of the North are hundreds of clear lakes, the largest of which are Red Lake (530 sq. m.), Mille Lacs, and Leech Lake. About two-thirds of the state is prairie, but in the northern portion there are extensive pine-forests, and in the north-east great marshes, bearing a scanty growth of tamarack and fir. The minerals include iron (in which it stands first in the Union), slate, granite, and other rocks, and the red pipestone. The climate is bracing in winter, dry and equable; the annual mean temperature is about 45°. The rainfall is adequate and well distributed over the year.

Minnesota is an agricultural and till lately especially a wheat-producing state; its manufacturing as yet are principally flour and lumber mills. The principal crop is no longer wheat but corn. Oats and hay and forage are the next important crops. The Mississippi is navigable as high as St Paul and Minneapolis; the lakes, with Duluth for a port, open a waterway to the Atlantic; and there are over 10,000 miles of railway.

Education is well cared for. There are a number of state normal schools, and a state university at Minneapolis, besides Macalester College (Presbyterian) and Hamline University (Methodist) at St Paul, Carleton College (Congregationalist) at Northfield, St John's University (Roman Catholic) at Collegeville, and many other colleges. The percentage of illiterates is one of the lowest in the United States. Foreign-born whites, chiefly Scandinavians and Germans, make up about 20 per cent. of the whole population.

History.—Minnesota was visited by French explorers in 1659–60, and the portion west of the Mississippi was part of the province of Louisiana purchased by the United States from France in 1803. Fort Snelling, at the mouth of the Minnesota River, was built and occupied in 1821. In 1837 the Chippeway Indians surrendered all the land east of the Mississippi; immigration then began, and Minnesota became a territory in 1849, a state in 1858. It claims the distinction of having, through its governor, offered the first regiment for the defence of the Union; and during the civil war, out of 40,000 citizens able to bear arms, it sent 24,000 into the army. In August 1862 occurred a terrible massacre by the Indians, who attacked

the frontier settlements, and in ten days killed some 800 men, women, and children. As a consequence the Sioux and Winnebagoes were removed from the state, and their hunting-grounds are now occupied by farms and prosperous towns. The principal cities are St Paul, the capital (234,698), Minneapolis (380,582), and Duluth (98,917). Pop. (1860) 172,023; (1890) 1,301,826; (1900) 1,751,394; (1910) 2,075,708; (1920) 2,387,125, including 8809 negroes and 8761 Indians.

Minniwaukeeon, or **DEVIL'S LAKE**, a salt lake in North Dakota (q.v.).

Minnow (*Phoxinus phoxinus*), a small freshwater fish closely related to chub and dace. It is covered with small scales, from eighty to over a hundred in a longitudinal series. It occurs in most parts of Britain except the northern Highlands, and in most parts of Europe except the Iberian Peninsula. Its length is usually 3 or 4 inches, but specimens of 6 or 7 inches are recorded. The coloration is very variable, but often silvery-gray combined with green, gold, brown, and black. The favourite habitat is in clear streams with sandy or gravelly bottom. Migrations in search of food or away from foul water are common, a shoal following adventurous leaders. Gregariousness and curiosity are characteristics. In summer the minnows frequent shallows; in winter they seek deep water and hide under stones or below the banks. The food consists chiefly of insect-larvæ, worms, freshwater crustaceans and molluscs, and the eggs and small fry of other fishes. Minnows are themselves preyed on by larger fishes; hence their use as bait for trout, perch, pike, and eels. They are palatable as food, and are sometimes served as 'whitebait.' The spawning is in May and June, and at that time the males show whitish tubercles on their black head and a scarlet belly. The eggs are laid in gravelly shallows and adhere to stones; the development is rapid. After fertilising the eggs the males seem to have a resting period of several days, lying close together in shoals. Recovering themselves, they resume the characteristic activity of the species. See C. Tate Regan's *Fresh-water Fishes of the British Isles* (1911).

Minoan Culture. See CRETE.

Minor is, in Scots law, the term describing a person who, if a male, is between the ages of 14 and 21; and if a female, is between 12 and 21. In England the technical term is an Infant (q.v.).

Minor. See SCALE.

Minor Barons. See BARON.

Minorca (Span. *Menorca*), the second largest of the Balearic Isles (q.v.), lies 25 miles NE. of Majorca. It is 28 miles long, by an average of 10 wide, and has an area of 284 sq. m. Pop. 42,000. Its coast is rocky and inaccessible, but broken by numerous inlets, and its surface low, undulating, and stony. Its productions and climate are similar to those of Majorca, though the soil is less fertile. The chief towns are Port Mahon (q.v.) and Ciutadella (9600). The island is remarkable for its great number of ancient megalithic remains (called talayots) and its stalactite caves (at Prella). See BYNG (JOHN).

Minorites. See FRANCISCANS.

Minority. See REPRESENTATION.

Minos, the name of two mythological kings of Crete (q.v.). The first is said to have been the son of Zeus and Europa, the brother of Rhadamanthus, the father of Deucalion and Ariadne, and, after his death, a judge of the shades in Hades.—The second, grandson of the former, was son of Lycastus and Ida, and, with Zeus's help, author of the Laws of Minos. Homer and Hesiod know only one Minos, son and friend of Zeus and king of Knossos, where

in 1900-5 Evans laid bare the vast substructure of what may have been his palace.

Minotaur, one of the most repulsive conceptions of Greek Mythology, the offspring of Pasiphaë and a bull, for which she had conceived a passion, gratified through the contrivance of Poseidon. The queen placed herself in an artificial cow made by Dædalus, and so became the mother of the monster, half-man half-bull, a man with a bull's head. Minos, the husband of Pasiphaë, shut him up in a Knossian Labyrinth, and there fed him with the seven youths and seven maidens whom Athens was obliged to supply at fixed periods as a tribute, till Theseus, with the help of Ariadne (q.v.), slew the monster.

Minquiers. See CHANNEL ISLANDS, JERSEY.

Minsk, capital of White Russia, on an affluent of the Beresina, 331 miles by rail ENE. of Warsaw. Pop. about 130,000, many of whom are Jews. The town existed in the 11th century, was Lithuanian in the 13th and Polish in the 15th, and was annexed by Russia in 1793. It is claimed by Lithuania. A university was founded by the Soviet government.

Minster (Lat. *monasterium*, 'a monastery'), the church of an abbey or priory; but often applied, like the German *Münster*, to cathedral churches without any monastic connection, as especially to York Minster.

Mint (*Mentha*), a genus of plants, of the natural order Labiate, with small, funnel-shaped, quadrid, generally red corolla, and four straight stamens. The species are perennial herbaceous plants, varying considerably in appearance, but all with creeping root-stocks. The flowers are whorled, the whorls often grouped in spikes or heads. The species are widely distributed over the world. Some of them are very common in Britain, as Water Mint (*M. aquatica*), which grows in wet grounds and ditches, and Corn-mint (*M. arvensis*), which abounds as a weed in cornfields and gardens. All the species contain an aromatic essential oil, in virtue of which they are more or less medicinal. The most important species are Spearmint, Peppermint, and Pennyroyal.—Spearmint or Green Mint (*M. viridis*) is a native of almost all the temperate parts of the globe; it has erect smooth stems, from one foot to two feet high, with the whorls of flowers in loose cylindrical or oblong spikes at the top; the leaves lanceolate, acute, smooth, serrated, destitute of stalk, or nearly so. It has a very agreeable odour.—Peppermint (*M. piperita*), a plant of equally wide distribution in the temperate parts of the world, is very similar to spearmint, but has the leaves stalked, and the flowers in short spikes, the lower whorls somewhat

Spearmint (*Mentha viridis*).

distant from the rest. It is very readily recognised by the peculiar pungency of its odour and of its taste.—Pennyroyal (*M. Pulegium*), also very cosmopolitan, has a much-branched prostrate stem, which sends down new roots as it extends in length; the leaves ovate, stalked; the flowers in distant globose whorls. Its smell resembles that

of the other mints.—All these species, in a wild state, grow in ditches or wet places. All of them are cultivated in gardens; and peppermint largely for medicinal use and for flavouring lozenges. They are naturalised in America, where, however, the common species is *M. canadensis*, the Wild or Horse-mint. *Mint Sauce* is generally made of spearmint, which is also used for flavouring soups, &c. A kind of mint with lemon-scented leaves, called Bergamot Mint (*M. citrata*), is found in some parts of Europe, and is cultivated in gardens. Varieties of peppermint and Horse-mint (*M. longifolia*), with *crisped* leaves, are much cultivated in Germany under the name of Curled Mint (*Krause-minze*): the leaves are dried and used as a domestic medicine, and in poultices and baths. All kinds of mint are easily propagated by parting the roots or by cuttings. It is said that mice have a great aversion to mint, and that a few leaves of it will keep them at a distance. Peppermint, pennyroyal, and spearmint are used in medicine. The pharmacopœias contain an *aqua*, *spiritus*, and *oleum* of each of them; the official part being the herb, which should be collected when in flower. *Peppermint* is a powerful diffusible stimulant, and, as such, is antispasmodic and stomachic, and is much employed in the treatment of gastrodynia and flatulent colic. It is also extensively used in mixtures, for covering the taste of drugs. *Pennyroyal* and *spearmint* are similar in their action, but inferior for all purposes to peppermint.

Mint (Lat. *moneta*), an establishment for making coins or metallic money (see MONEY). The early history of the art being traced under the head Numismatics, the present article is mostly confined to a sketch of the constitution of the British mint, and of the modern processes of coining as there followed.

In Canute's laws, an officer called a 'reeve' is referred to as having some jurisdiction over the mint, and certain names which, in addition to that of the sovereign, appear on the Anglo-Saxon coins seem to have been those of the moneyers, an important class of functionaries, who were, until the operations of coinage were undertaken by the state in 1851, responsible for the manufacture of the coin. Besides the sovereign, barons, bishops, and the greater monasteries had the control of mints, where they exercised the right of coinage, a privilege enjoyed by the archbishops of Canterbury in the reign of Henry VIII., and by Wolsey as Bishop of Durham and Archbishop of York. After the Norman Conquest the officers of the Royal mint became to a certain extent subject to the authority of the exchequer. Both in Saxon and Norman times there existed, under control of the principal mint in London, a number of provincial mints in different towns of England; there were no fewer than thirty-eight in the time of Ethelred. The officers of the mint were formed into a corporation by a charter of Edward III.; they consisted of the warden, master, comptroller, assay-master, workers, coiners, and subordinates. Coining at the Scottish mint in Edinburgh began in the reign of David I. (1124-53), and ceased with the Union; but the office of governor of the mint was not incorporated with the English one till 1817. The early Scottish coinage followed very closely the English model and the English types of coin; after the war of independence there was a series of new denominations.

The seignorage for coining at one time formed no inconsiderable item in the revenues of the crown. It was a deduction made from the bullion coined, and comprehended both a charge for defraying the expense of coinage and the sovereign's profit in virtue of his prerogative. By 18 Car. II. chap. 5

the seignorage on gold was abolished, and it has never since been exacted. The 'shere' or 'remedy,' as it is now called, is an allowance for the unavoidable imperfection of the coin in regard to both standard weight and fineness.

The function of the mint, so far as concerns the standard gold coinage, is to receive gold in ingots from individuals, and return an equivalent weight in sovereigns. But, in point of fact, gold is now exclusively coined for the Bank of England; for, although any one has the right to import gold into the mint for coinage, receiving an equivalent weight of sovereigns at the rate of £3, 17s. 10½d. per oz. standard, after a sufficient delay to allow of the gold he imports being converted into coin, he can at once receive payment on presenting his bullion at the Bank of England at the slightly lower rate of £3, 17s. 9d., and the additional 1½d. offered by the mint is not found sufficient to compensate for the necessary delay which occurs.

Silver, which was formerly a legal tender to any amount, has, by 56 Geo. III. chap. 68, ceased to be so. That act provided that each troy pound of standard silver should be coined into sixty-six shillings, and, since this exceeds the price at which the metal in its uncoined state can be purchased, it follows that the coinage of silver is a source of profit to the state. When the price fell to 42½d., this profit, or seignorage, amounted to no less than 54 per cent.; but in 1908-12 the price of silver averaged only about 24d. or 25d. In 1924 the average price was 34d. But in 1920 the price rose as high as 89½d., and in consequence a Coinage Act was passed reducing the fineness from 925 to 500. It should, however, be borne in mind that this 'token' coinage is only a legal tender to a limited amount (forty shillings), whereas gold coin is legal tender to any amount. The profit derived from the bronze token coinage is proportionately even greater. The seignorage, which was formerly retained by the master of the mint to defray the expense of coinage, has since 1837 been paid to the credit of the Consolidated Fund.

A new mint was erected on Tower Hill in 1810. In 1815 some alterations were made in its constitution; and in 1851 a complete change was introduced in the whole system of administration. The control of the mint was then vested in a master, a deputy-master, and a comptroller. The mastership, which had, in the early part of the 19th century, become a political appointment held by an adherent of the government, was restored to the position of a permanent office, the master being the ostensible executive head of the establishment. The operative department was entrusted to the assayer, the melter, and the refiner. The moneyers, who had from early times enjoyed extensive privileges and exemptions, and were contractors with the crown for the execution of the coinage, were abolished, and the contracts with the crown were entered into by the master of the mint, who also made subordinate contracts for the actual manufacture of the coin. In 1869 the mastership was added to the duties of the Chancellor of the Exchequer, and the offices of deputy-master and comptroller were amalgamated. Mints were established at Sydney, Melbourne, and Perth to coin the gold so largely found in Australia, in 1853, 1869, and 1899 respectively. In 1908 a branch mint was established at Ottawa for striking sovereigns, and also gold, silver, and bronze coins of special design for the government of Canada. A similar branch was set up in 1922 at Pretoria to strike sovereigns and to supply local currency for the Union of South Africa. Coins for circulation in British India are supplied by the mints at Calcutta and Bombay.

Processes of Coining.—Down to the middle of the 16th century little or no improvement seems to have been made in the art of coining from the time of its invention. The metal was simply hammered into slips, which were afterwards cut up into squares of one size, and then forged round. The required impression was given to these by placing them in turn between two dies, and striking them with a hammer. As it was not easy by this method to place the dies exactly above each other, or to apply proper force, coins so made were always faulty, and had the edges unfinished, which rendered them liable to be clipped. The first great step was the application of the screw-press to the process of coining by the celebrated artist, Benvenuto Cellini. The plan was expensive at first, and not till 1662 did it altogether supersede the hammer in the English mint. In 1910-11 gas-fired furnaces were introduced for melting purposes in place of those heated by coke fuel. The chief steps in coining as now practised are as follows: The gold or silver to be coined is sent to the mint, for the most part in the form of *ingots* or castings; those of gold weighing about 400 ounces, while the silver ingots are much larger. Before melting, each ingot is weighed and tested as to its purity by Assaying (q.v.). For melting the gold, pots or crucibles of plumbago are used, made to contain each about 2600 ounces. The pots being heated in furnaces to a bright red heat, the charge of gold is introduced along with the amount of copper which calculation, based on the weight of the gold and its composition as ascertained by assay, proves to be necessary in order to bring it to the standard, which in Great Britain is 22 parts of pure gold to 2 of copper (see ALLOY). The metal, when melted, is poured into iron moulds, which form it into bars 26½ inches long, 1½ inch broad, and five-eighths of an inch thick, if for sovereigns; and somewhat narrower if for half-sovereigns. For melting silver (the alloy of which is adjusted to the standard of 222 parts of silver to 18 of copper) larger plumbago crucibles capable of containing upwards of 6000 ounces are used, and the metal is cast into bars similar to those of gold.

The copper, or rather bronze, coinage, first issued in 1860, is formed of an alloy consisting of 95 parts of copper, 4 of tin, and 1 of zinc. The coins are only about half the weight of their old copper representatives. The processes of casting and coining the bronze are essentially the same as in the case of gold and silver.

The operation of *rolling* follows that of casting. It consists in repeatedly passing the bars between pairs of rollers with hardened steel surfaces, driven by electric power; the rollers being brought closer and closer as the thickness becomes reduced. At a certain stage, as the bars become longer, they are cut into convenient lengths; and, to reduce the hardness induced by the pressure, they are annealed. The finishing rollers are so exquisitely adjusted that the *fillets* (as the thinned bars are called) do not vary in thickness in any part more than the ten-thousandth part of an inch. The fillets were further adjusted in the British mint by the 'draw-bench' (discontinued in 1905), in which they were drawn between steel blocks, as in wire-drawing. The fillets thus prepared are passed to the tryer, who, with a machine-punch, cuts a trial-blank from each, and weighs it in a balance, judging by experience whether the variation found to exist from the strict legal weight is such as to justify his passing the fillet into work.

The *blanks* of which the coins are to be made are cut out by means of punching-machines of simple construction, in which two or more short steel plungers are forced by an eccentric through the fillet, and enter holes in the bed of the machine;

the fillet is then advanced automatically and the operation repeated. The scrap left after the blanks are cut out, called *scissel*, is sent back to be remelted.

To ensure their being properly marked on the edge, the blanks are pressed edgewise in a machine between two grooves, one in a fixed steel block, and the other in the face of a revolving steel disc, whereby the edge is raised and the blanks are brought to a uniform diameter. After this they are annealed to soften them, before they can be struck with dies; except in the case of gold they are also dipped into hot dilute sulphuric acid to remove oxide of copper from the surface. Subsequently they are washed with water, and dried in hot sawdust.

We now come to the press-room, where the blanks receive the impression which makes them perfect coins. The screw coining-presses which were erected in the mint in 1810 were superseded in 1882 by lever presses of what is known as the Uhlhorn pattern. Of these no less than eighteen now exist in the mint. It is not necessary to give any detailed account of their mode of action, but it may be explained that the lower die (see DIE-SINKING) is fixed, and, after the blank has been automatically laid on it, a steel collar which is milled on the inside rises so as to surround this blank, and, while it is thus enclosed, the upper die descends upon it, considerable pressure being applied through a lever acting on a toggle joint. It will thus be seen that at the moment at which the pressure is applied the blank is completely enclosed, the result being that all the details which exist on the two dies and the 'milling' on the collar are reproduced in the comparatively soft metal of the blank. The upper die then immediately rises, the collar descends, and the now finished coin is automatically pushed on one side to give place to another blank. In cases where letters are put on the edge of a coin, a collar divided into segments working on centre pins is used. On the proper pressure being applied, the segments close round and impress the letters on the edge of the coin. It is possible to strike coins at the rate of no less than 120 per minute, but it is found that the best results are obtained when the number does not exceed 90 per minute.

After being examined with a view to remove any faulty pieces, the finished coins are now passed on to be weighed in the automatic balances, since the act regulating the coinage (33 Vict. chap. 10) provides that no gold or silver coin shall be issued from the mint which varies by more than a specified and very small amount from the exact legal standard weight. These very beautiful instruments, which were introduced in 1844 by William Cotton, governor of the Bank of England, but have since been much modified and improved, are each capable of weighing about twenty-three coins per minute within $\frac{1}{1000}$ th of a grain, and distributing them into three separate compartments, respectively for those which are too heavy, too light, or within the limits of weight allowed by law. The first two classes are returned to be melted, while the third class, having been rung on iron anvils with a view to eliminate such as are 'dumb,' are, so far as their manufacture is concerned, ready to be issued to the public. It is first necessary, however, that sample coins be taken for assay, as a final guarantee that they are within the limits as regards standard fineness allowed by the coinage act.

The gold coin is delivered to the importer (generally the Bank of England) as soon as finished, the weight of coin being the equivalent of that of the bullion imported, without making any deduction for loss in the operations of coinage or for the cost of alloying metal. Silver coin, however, is made

up in bags of £100 nominal value, and stored in the mint until required by the Bank of England, Scotland, or Ireland for distribution in those countries, or by the government of a British colony in which imperial silver coin circulates. In the same way bronze coin is made up in bags of £5 nominal value and kept in store.

The following table gives the full legal weight in grains of all Imperial coins of gold, silver, and bronze:

Denomination.	Weight in Grains.	Denomination.	Weight in Grains.
GOLD.		SILVER.	
Five pounds	616.3724	Sixpence	43.6363
Two pounds	246.5489	Fourpence (Maundy) ..	29.0909
Sovereign	123.2744	Threepence	21.8182
Half-sovereign	61.6372	Twopence (Maundy) ..	14.5454
SILVER.		Penny (Maundy)	7.2727
Crown	436.3636	BRONZE.	
Double florin	349.0909	Penny	145.8333
Half-crown	218.1818	Halfpenny	87.5000
Florin	174.5454	Farthing	43.7500
Shilling	87.2727		

It will be noticed that in the case of both gold and silver the values are in proportion to the weights of the coins, but that this is not the case as regards bronze: whereas a ton of pence is nominally worth £448, the same weight of halfpence or farthings is only valued at £373, 6s. 8d.

Coins are also struck in the London mint for many of the colonies and oversea dominions, as well as foreign governments. These include special coinages for Cyprus, Guernsey, Jersey, Malta; Ceylon, Hong-kong, Mauritius, Straits Settlements; East Africa and West Africa; British Guiana and West Indies, British Honduras, Jamaica, Newfoundland; and the Commonwealth of Australia. The colonial coins are issued in various metals, including gold, silver of 925, 900, and 800 fineness, bronze, and nickel-bronze, the nominal value being based upon the local unit of currency. The mint produces also the various naval and military medals with their bars and clasps, as well as the medals of learned and scientific societies. In 1911 the preparation of plates for printing British postage stamps, and of dies for inland revenue stamps, was transferred to this department.

In the United States a mint was established at Philadelphia in 1792; and next century additional mints were set up at San Francisco, New Orleans, and Carson City, besides eight assay-offices.

Minto, SIR GILBERT ELLIOT, first EARL OF, was born at Edinburgh, 23d April 1751. As a boy he spent two years at a school at Fontainebleau under the eye of David Hume, and, after passing through the universities of Edinburgh and Oxford, in 1769 entered Lincoln's Inn, and was called to the bar in 1774. Two years later he entered parliament as a supporter of Lord North, but from 1782 attached himself to Fox and Burke. In 1794-96 he was viceroy of Corsica. He was created Baron Minto in 1797, and went out to India as governor-general in 1806. He showed great vigour in his measures for establishing order and securing the frontiers by treaties, like that of Amritsar with Ranjit Sing. He captured Mauritius, Bourbon, and Java; returning, as Earl of Minto, only to die 21st June 1814. See his *Life and Letters* (1874-80).—His great-grandson, the fourth Earl (1847-1914), was governor-general of Canada in 1898-1904, and as viceroy of India in 1905-10 had to cope with 'unrest' in Bengal and elsewhere. See *Life* by Buchan (1924).

Minucius Felix, an early Latin apologist, whose name survives through his *Octavius* (trans. Freese, 1919), a dialogue held on the beach at Ostia, between the pagan Cæcilius Natalis and the Christian Octavius Januarius. The latter succeeds in convincing his opponent. His Christianity shows no trace of such distinctive dogmas as that of the

resurrection. Cyprian's *De Idolorum Vanitate* borrows from *Octavius*; as also does Tertullian's *Apologeticus*, according to most scholars.

Minuet, the air of a graceful dance, originally from Poitou, in France, performed in a slow tempo. The music is in $\frac{3}{4}$ -time, with a trio.

Minusinsk, a town of Siberia, on the Yenesei, about 200 miles SSW. of Krasnoyarsk. For remarkable archaeological finds, see **ART**.

Minute. See **DAY**, **DEGREE**.

Minute Men, in the American Revolution, were the militia, who were prepared for service at a minute's notice.

Minyas, in Greek Mythology, the son of Chryses, the eponymous hero of the *Minyæ*, from whom were descended most of the Argonauts. He built the city of Orchomenus. His three daughters, Clymene, Iris, and Alcithoë, or Leuconoë, Leucippe, Alcithoë, were changed into bats for having made light of the mysteries of Dionysus.

Miocene System (Gr., 'less recent'). The name was applied by Lyell to that division of the Tertiary strata which contains a smaller proportion of recent species of Mollusca than the Pliocene System (q.v.), and a larger proportion than the Eocene. Of late years the lower part of the Miocene has been separated from that system, and now ranks as a separate system (see **OLIGOCENE**). No true Miocene deposits occur in Britain. Marine accumulations of this age are sparingly developed in Belgium (Black Crag), and cover considerable areas in the low grounds of Touraine (*Faluns de la Touraine*) in the west of France. In the Rhine valley Miocene beds extend from the Taunus southwards (Mainz Basin). These beds are chiefly of fresh-water origin—the lower portion being marine. A more important Miocene area is met with in the Vienna Basin. Here the lower series of beds is marine, while the overlying strata are less distinctly so, many of the fossils indicating brackish-water conditions. Another interesting development of Miocene occurs in Switzerland and South Bavaria—the beds being partly marine and partly of fresh-water origin. These are the more important European areas. In North America marine Miocene strata occur sparingly on the Atlantic borders of the eastern states; while fresh-water deposits of the same age are widely spread in the western states and territories. Miocene beds have been met with far within the Arctic Circle, in Greenland and Spitsbergen.

Life of the Period.—The flora of the earlier stages of the Miocene of central Europe is indicative of somewhat tropical conditions, the nearest representatives of many of the more characteristic plants being now confined to India and Australia. Palms seem at that time to have flourished over a large part of Europe, and with these were associated conifers (*Sequoia*, *Libocedrus*), evergreen oak, fig, laurel, cinnamon, various proteaceous plants (*Banksia*, *Dryandra*), olive, magnolia, maple, myrtle, mimosa, acacia, &c. Later on the climate became more temperate, for we meet with species of birch, alder, oak, beech, chestnut, plum, willow, poplar, &c. Among the more notable terrestrial animals of the Miocene were *Dinotherium*, *Mastodon*, *Anchitherium*, *Hyotherium*, species of rhinoceros, tapir, fox; a gigantic form of ant-eater (*Macrotherium*); *Helladotherium*, allied to the giraffe; *Machairodus*, a lion-like, sabre-toothed carnivore; various antelopes and deer with small horns and antlers; opossums, apes, and monkeys. The molluscs of the marine Miocene are all modern types—those of the older strata having a tropical or subtropical facies, while the shells in the younger strata seem, like the plants, to indicate milder climatic conditions.

In Miocene times the British area was probably dry land, and the same appears to have been the case with all northern Europe. The sea, however, overflowed the low grounds of Belgium and extended into north-west Germany. It is not unlikely, indeed, that most of the Low Countries, Hanover, and Sleswick-Holstein, were at that time submerged. In like manner the sea covered wide areas in the north-west and west of France, extending into the heart of the country now drained by the Loire and its affluents the Cher and the Indre, and stretching across the old district of Aquitania to the Mediterranean. Spain and Portugal then formed an island, considerable tracts in the south and east of Spain being submerged. From the Gulf of Lions a long arm of the sea passed up the valley of the Rhone, and swept north-east through northern Switzerland, sending a branch into the Mainz basin, and then traversing Bavaria, across which it continued to the wide sea which then occupied all the great plains of Hungary. Northern and eastern Italy were at the same time under water, as was also the case with many parts of eastern Europe and Asia Minor. Southern Europe was thus in the Miocene period an extensive archipelago, in which the plateaus of Spain and central France, the Alps, the Carpathians, &c. existed as islands. The most continuous land-mass was in the north of Europe: and if the Miocene of the Arctic regions, with its abundant flora, be of the same age as the Miocene of Europe, then we may infer that a vast area of the North Atlantic existed as dry land, across which migrations of the flora took place. Considerable movements of elevation seem to have occurred in Europe before the close of Miocene times, causing the sea to disappear from wide regions which it had formerly occupied. Thus, the Mainz basin and the sea that occupied much of northern Switzerland, &c. were replaced by fresh-water lakes, while the wide sea of the Vienna basin was much reduced in size, and eventually became freshened—the conditions resembling those that characterise the Black Sea.

Miquelon, **GREAT** and **LITTLE**, two islands connected by a long, narrow, sandy isthmus, off the south-west coast of Newfoundland, forming with St Pierre the sole remaining colony of France in northern America. Fishing is nearly the sole occupation, and dried and fresh cod and cod-liver oil are exported. Area of the Miquelon group, 83 square miles; pop. 500.

Mir, the Russian commune, consisting of the inhabitants of one or more villages, who are as a community owners of the surrounding land, and redistribute the same to the members from time to time. See **LAND LAWS**, **RUSSIA**, **VILLAGE COMMUNITIES**.

Mirabeau, **VICTOR RIQUETI**, **MARQUIS DE**, father of the great statesman of the French Revolution, was born, October 5, 1715, at Pertuis in Provence, of a family that claimed a noble Florentine descent, but was really sprung from a wealthy bourgeois family of Digne and Marseilles that had acquired in 1570 the domain of Mirabeau by purchase, and the title in 1685. He was an able but eccentric and exceedingly hot-headed and self-willed man, and he showed himself a senseless and brutal tyrant in the treatment of his family. It is said that he procured at one time or other no fewer than fifty-four *lettres de cachet* against his wife and children, and he strove to curb the extraordinary genius of his greatest son by a course of unnatural severity, which ended with shattering all the ties of kindred and driving him into the most defiant and reckless excesses. Yet he was himself a theoretical philanthropist and active promoter of physiocratic ideas, and in this cause

published a series of books, as *Ami des Hommes* (1755) and *La Philosophie rurale* (1763), whose vigorous phrasing often foreshadows the stronger hand of his son. He died 13th July 1789.

See Loménie, *Les Mirabeau* (1878-89); Oncken, *Der ältere Mirabeau* (1886); Ripert, *Le Marquis de Mirabeau* (1901).

HONORÉ GABRIEL RIQUETI, COMTE DE MIRABEAU, the greatest figure in the French Revolution, and perhaps the ablest statesman that France has yet produced, was born at Bignon in Provence, 9th March 1749, of a family that had been for three generations famous for stormy passions and great abilities. Within his vigorous frame and massive intellect were concentrated all the good and all the evil of his race; his unusually ugly face, scarred with smallpox and crowned with an immense mane of black hair, bore unmistakably the stamp of power, and from boyhood he possessed a marvellous personal fascination which subdued all men and women to his will. His education was left to take care of itself, and at seventeen he entered as a lieutenant the Berri regiment of cavalry, and lived a life of such recklessness at the little garrison-town of Saintes that his imperious father imprisoned him in 1768 on the Isle of Rhé, near La Rochelle, and next sent him with the French legion of Lorraine to Corsica, where his conduct earned him the confidence of his chiefs and the affection of his men. But his father refusing to purchase him a company, he left the service in 1770, and settled down to practise the physiocrat system on an estate in Limousin. Two years later his father married him to the only daughter of the Marquis de Marignan, a sprightly and pretty, but vain and shallow woman, with whom he broke out into lavish expenditure, and lived unhappily. On account of his debts his father confined him, in May 1773, in the town of Manosque, next in the Château d'If, near Marseilles, and at last in 1775 in the castle of Joux, near Pontarlier. Here he formed an intrigue with Sophie de Ruffey, the young wife of the gray-haired legal president, the Marquis de Monnier, and fled with her to Switzerland and thence to Amsterdam, where for eight months he made his bread by laborious hack-work for the Dutch booksellers, among other tasks translating from the English Watson's Life of Philip II. His *Essai sur le Despotisme*, begun at Manosque and now completed, made a sensation by its audacity and vigour. Meantime the parliament of Besançon sentenced him to the penalty of death, in contumacious absence, for abduction and robbery, and caused a paper effigy of him to be beheaded. The search made for him at the instigation of his father at length proved successful, and in May 1777 he was handed over by the States-general and flung into the frowning castle of Vincennes, where, in a close imprisonment of three years and a half, and after he had worked off his grosser feelings in writing the indecent *Erotica Biblion* and *Ma Conversion*, he worked out his own salvation by study and meditation, and the writing of his famous *Essai sur les Lettres de Cachet et les Prisons d'État* (2 vols. 1782). His too glowing letters from the prison to Sophie were discovered later by Manuel in the archives of police at Paris, and published under the title of *Lettres originales de Mirabeau, écrites du Donjon de Vincennes* (4 vols. 1792). In December 1780 Mirabeau was released, and he at once began by a bold process to labour for his restoration to society. At length, September 1782, after eloquent pleadings that drew upon him all eyes in France, he succeeded in getting his sentence annulled. Next year he lost his suit at Aix for the restitution of his conjugal rights, but did something by the attempt to rehabilitate his reputation. Now also

he broke off the illicit relation with his mistress, who had not remained true to him, and whose later disappointments in love drove her to the refuge of suicide in September 1789.

Again flung upon his own resources, deeply drowned in debt, and thriftless and extravagant by temperament, Mirabeau made for some years a shifty living by his pen, writing and compiling innumerable books and pamphlets against speculation, stock-jobbing, and other political and social evils of the time, and flitting restlessly from France to Prussia, to Holland, and to England. His grosser passions had not yet burned themselves out, and his life was stained by countless unworthy *liaisons*, amid which one woman alone—the Dutch Madame de Nehra—stands out as an elevating influence. In England he was intimate with Sir Gilbert Elliot, afterwards first Earl of Minto, Lord Lansdowne, and Romilly, and his close observation of English politics taught him the good of moderation, compromise, and opportunism. In 1786 he was sent by the French government on a secret mission to Berlin, and there from Major Mauvillon he obtained the materials for his work, *Sur la Monarchie Prussienne sous Frédéric le Grand* (4 vols. 1787). When the States-general was convened he offered himself as a candidate to the nobles of Provence, and was rejected, whereupon he turned to the *tiers état* and was returned enthusiastically for both Marseilles and Aix. He chose to sit for the latter, and, badly received though he was at first, soon showed himself a born leader of men, as well as the one really practical statesman in the Assembly. On the 17th June, on the motion of Sieyès, the *tiers état* constituted itself as the National Assembly, and on the 23d Mirabeau made his memorable answer to the royal messenger, the Marquis de Dreux-Brézé, who had come from the king to command the deputies to separate: 'If you have orders to remove us from this hall, you must also get authority to use force, for we shall yield to nothing but to bayonets.'

Mirabeau's political sagacity and foresight quickly made him a great force in the Assembly, while his audacity and volcanic eloquence made him at once the darling of the mob and the terror of the court. Meantime he extended his influence by unceasing diligence in journalistic work, and for his *États-Généraux*, *Lettres à mes Conmectants*, and *Courrier de Provence*, drew on the knowledge and abilities of a host of coadjutors, such as the Genevese Duroveray and Étienne Dumont. Moved by his instinctive dread of anarchy, he proposed the establishment of a citizen-guard, out of which grew the National Guard, but he trembled at the 'nocturnal orgies' of August 4, 1789, when in the breathless legislation of a single night were swept away together serfdom, feudal jurisdiction, manorial ground-rents, tithes, game-laws, saleable offices, fees, clerical robing dues, municipal and provincial privileges, privileges of rank, exemptions from taxes, and plurality of offices and livings. None of his contemporaries equalled him in breadth of view, temperance in judgment, and freedom from prejudice—no actor in the great drama save himself saw that 'the notion of equality is only a fit of the revolutionary fever.' He saw clearly the fatuity of such schemes as the foolish Lafayette's theatrical declaration of the rights of man, pointing out that such a thing might well enough be done after the work of constructing the constitution had been accomplished. Mirabeau was not personally responsible for the furious *émeute* of October 5 and 6, which brought the king to Paris, for indeed hatred of anarchy was his most deeply-rooted political principle. As early as May 1789 he had tried in vain to come to terms with Necker and Lafayette, yet his character was too magnanimous

to desire revenge for the rebuffs with which his overtures had been received. He formed a warm friendship with the Count de la Marck, a particular friend of Marie Antoinette, and in conjunction with him he drew up his first memoir for the guidance of the court, just after the transference of the king and Assembly to Paris. In this admirable paper he set forth the necessity for a new constitution, the initiative to come from the king; that all that had been passed must be ratified, and a responsible ministry appointed after the pattern of the English parliamentary usage; and that the king must leave Paris for some such loyal city as Rouen, and throw himself frankly upon France. He suggested a ministry, with Necker and Lafayette as its prominent members, himself to have a seat but no portfolio. But the infatuated queen detested and distrusted the great tribune, and the Assembly, mad with suspicion and fear, passed a suicidal self-denying ordinance (November 7, 1789) that no member should take office under the crown while holding his seat, or for six months after. Mirabeau's hopes were thus blasted for the time, yet he worked on with unabated energy. He surrounded himself with a group of able and enthusiastic friends who provided him with his facts, and even wrote for him his speeches and articles, content to efface themselves to enhance a beloved master's glory. Never was there so marvellous a collaboration of unpaid enthusiasm: Dumont wrote the political speeches; Clavière, the financial; the Abbé Lamourette, those on the civil constitution of the clergy. Pellenc, the private secretary, constantly accumulated facts; the Genevese Keybaz wrote the speeches on the assignats, and on the right of making war and peace. The orator took freely these materials so generously prepared for him, fused them in the alembic of his own marvellous genius, and stamped them afresh with the impress of his own individuality.

In the spring of 1790 communication opened anew with the court, and fresh appeals were made to Lafayette. If Mirabeau was a bitter enemy of feudalism he was a devoted friend of order, and saw the necessity of a strong executive as its foundation, but he was constantly mortified to find himself mistrusted and misunderstood. His past rose up in judgment against him, and he could not gain the full confidence either of the respectable classes or of the court—as he himself said bitterly to Dumont, 'The sins which I committed in my youth are giving me their full punishment now.' The court provided money to pay his debts, which were scheduled at 208,000 livres—among them the bill for his wedding-clothes—and agreed to allow him 100 louis a month, with 300 livres for De Comps, his copyist, whereupon Mirabeau broke out into indiscreet extravagance. He risked all his popularity by successfully opposing Barnave's motion that the right of peace and war should rest not with the king but the Assembly. On the 3d July the queen gave him an interview in the gardens at Saint-Cloud, and at its close Mirabeau, with the fine chivalry of his nature, as he bent to kiss her hand, assured her with the words, 'Madame, the monarchy is saved.' But as the popular movement progressed his dream of placing the king at the head of the revolution became more and more a dream, and he was cut to the heart to find, as he did by the winter of 1790, that the court did not yet grant him its full confidence, but listened also to other counsellors than himself, and that it would not accept his plan of an appeal to the provinces. He inspired Montmorin in his management of foreign affairs, and showed himself a really great financier in his measures to avert national bankruptcy, while he continued to interchange notes of advice with the

court. His secret aim was now to undermine the popularity and influence of the Assembly, and compel it to dissolve. Neither counter-revolution nor foreign intervention were within his schemes, but the advent of a new assembly, which he hoped to guide to a moderate conception of liberty and to wise concessions to the throne. He suggested the establishment of a bureau of correspondence with the provinces, a publishing committee to buttress the cause of order with the throne as its centre, a plan for gaining over the chief members of the present Assembly in preparation for its dissolution, and an organised system of ascertaining the opinions of journalists and leading politicians. But the queen would not commit herself to the tribune, and Mirabeau's heart sank within him as he saw slip from his grasp his great dream of establishing a responsible parliamentary government in France. This summer his health and eyesight gave way alarmingly, but he refused to abate his giant labours. In December 1790 he was elected president of the Jacobin Club; as well as an administrator of the Seine department, and in the January following one of its eight directors; but by Lafayette's influence he was defeated in his candidature for the office of its procureur-general-syndic, as well as for the presidency. He was chosen, however, commandant of the battalion of National Guards of his district, and on 30th January 1791 was at last elected president of the Assembly for the fortnight. He overthrew the proposed law against emigration, and that same evening at the Jacobin Club bore down all opposition by his irresistible eloquence. He opposed the motion of Sieyès (22d March) that in the event of the king's death the regent should be elected by the Assembly, as an abandonment of the hereditary principle, and carried his point. But his health was fast sinking. On the last day of his life he said, 'I carry with me the ruin of the monarchy. After my death factions will dispute about the fragments.' On the morning of 2d April 1791, after a night of agony, when speech had gone, he wrote on a slate, 'Sleep—I wish only to sleep,' and a few moments after his heart had ceased to beat. He was buried in the Panthéon amid universal mourning. Another National Assembly, the Convention, two and a half years afterwards, when the papers revealing the secret relations of Mirabeau and the court were discovered in the king's iron chest, ordered the body to be disinterred from the Panthéon and cast into the churchyard of Sainte-Catherine.

English historians have generally with Carlyle looked on Mirabeau as the strong man who, had he lived, might have saved the state and checked the cataclysm of the Revolution. Recent French critics with other than English political experiences and prepossessions have refused to ignore his venality and crooked ways, and to assume that his scheme of a constitutional monarchy was practicable. Emphatically they knew he was *felix opportunitate mortis*. 'Just as at his death all factions agreed in praising him because all had points of agreement with him, so now all critics make their reservations because he went too far for some of them and not far enough for others.' Many of them, admitting that he was a man of great ability, perhaps a man of genius, hold that 'if he had lived he would have been exposed as a double-dealer who had taken bribes for his double-dealing, and would have been swept away, like so many other moderate men, by the revolutionary torrent.'

His writings were collected by Blanchard (10 vols. 1822). See the *Mémoires Biographiques, Littéraires, et Politiques de Mirabeau écrits par Lui-même, par son Père, son Oncle, et son Fils Adoptif* (8 vols. 1834; trans. 1835-36); Dumont, *Souvenirs sur Mirabeau* (1832); A. Stern, *Das Leben Mirabeaus* (2 vols. 1889); De Bacourt,

Correspondance entre le Comte de Mirabeau et le Comte de la Marck (1851); Loménie, *Les Mirabeau* (1878-91); Mézières, *Vie de Mirabeau* (1892, new ed. 1908); Reynald, *Mirabeau et la Constituante* (1873). The view of Mirabeau presented by Carlyle both in his *Essays* and in his *French Revolution* should be corrected by Willert's *Mirabeau* (1898), Warwick's *Mirabeau and the French Revolution* (1905), and *Mirabeau* by Louis Barthou (trans. 1913). See also books in French by Rousse (1891); in German by Erdmannsdörffer (1900); and in English by Trowbridge (1907), Tallentyre (1908), and Fling (1908 *et seq.*).

ANDRÉ BONIFACE RIQUETI, VICOMTE DE MIRABEAU, brother of the preceding, was born 30th November 1754 at Bignon, and from an early age was notorious for his ill-regulated life and for a thirst that earned him the nickname of 'Barrel Mirabeau.' It was, as he said, the only vice his brother had left him. He fought with distinction in the American war, and at the outbreak of the Revolution was returned to the States-general by the nobility of Limoges. Here he showed himself a fierce aristocrat in policy, and after the death of his brother he quitted France, and raised on the Rhine the 'Hussards de la Mort,' a legion of embittered *émigrés*, with whom he began in 1792 a bloody partisan warfare against his country. He was run through by accident, 15th September of the same year, at Freiburg im Breisgau.

Miracle (Lat. *miraculum*, 'a wonderful event'). The term is generally applied to extraordinary and altogether inexplicable actions produced by great personalities in the interests, generally speaking, of religion. Hence in the Old Testament the name is bestowed upon the supernatural effects produced by Moses (e.g. the parting of the Red Sea, the manna, &c.) and Elisha (e.g. the raising the dead boy to life) and other religious teachers. In the New Testament it is given to the wonderful works wrought by Jesus and his apostles.

In modern times the question as to the possibility of miracle has been the subject of constant debate. The discussion began with Hume's attack. 'A miracle,' says Hume, 'is a violation of the laws of nature; and as a firm and unalterable experience has established these laws, the proof against a miracle, from the very nature of the fact, is as entire as any argument can possibly be. The consequence is that no testimony is sufficient to establish a miracle unless the testimony be of such a kind that its falsehood would be more miraculous than the fact which it endeavours to establish.' The whole argument rests upon the assumption that 'a miracle is a violation of the laws of nature.' This definition, however, really begs the whole question, and is certainly at variance with the interpretations put upon miracles by many leading theologians. Augustine, for instance, strenuously contested this conception of miracle. 'God,' he says, 'does nothing against nature. When we say that he does so, we mean that he does something against nature as we know it, in its familiar ordinary way, but against the highest laws of nature he no more acts than he acts against himself' (*Contra Faustum*, xxvi. 3). A similar position was taken up in modern times by the Duke of Argyll. 'Miracles,' he argues, 'may be wrought by the selection and use of laws of which man knows, and can know, nothing, and which, if he did know, he could not employ.'

The debate on miracles falls into two parts. In part it is concerned with the question of metaphysical presuppositions, and in part it is concerned with the validity of the testimony available. Most theological problems are fought out beyond the frontiers of theology, and the question of miracles is a case in point. There are, it must be admitted, certain interpretations of the universe which rule miracles out of court at once. Materialism, which

explains everything by the action of material forces alone, has, of course, absolutely no room for the admission of a non-material agency into its scheme of things. Nor has Pantheism, which is, after all, only a spiritualised form of materialism. The Deistic interpretation is equally fatal to a belief in miracle, because it holds that after the first act of creation God retired from the universe and left it to work out its own fate. It is only those who believe in the existence of a God—and a God who is both transcendent and immanent in the life of the world—who can admit into their metaphysical explanation of the universe the possibility of miraculous intervention; in fact, on such a theory it is difficult to exclude the idea without destroying the whole conception of the personality of God. If freedom of action be a necessary element in personality, it seems impossible to deprive God of this prerogative without at the same time robbing him of personality. The assumption that God must always act according to uniform and invariable laws makes him the slave of his own system, and leaves him, as Lecky puts it, 'the only dormant spirit in the universe.' Moreover, there are clear indications that the action of God in governing the evolution of the world has, at times at any rate, assumed new forms. At the start of the process for instance—at the point where the inorganic passes into the organic—at the juncture where animal instinct becomes human reason and conscience, God seems to have broken with new power and force into the life of the universe. The very conception of Providence, too, assumes freedom on the part of God to vary his action in the interests of the development of human character. Prayer, too, is an empty form unless the assumption of the possibility of Divine intervention be maintained. In fact, the presuppositions of prayer are exactly the same as the presuppositions of miracle, and any theory which destroys the possibility of the one is fatal also to the other. But the question for us to-day turns not so much upon the *a priori* possibility of miracle, as upon the validity of the evidence. Huxley, for instance, once said: 'I have not the slightest objection to offer *a priori* to all the propositions in the three creeds. The mysteries of the Church are child's play compared with the mysteries of nature. The doctrine of the Trinity is not more puzzling than the necessary antinomies of physical speculation. . . . It would be a great error, therefore, to suppose that the agnostic rejects theology because of its puzzles and wonders. He rejects it simply because in his judgment there would be no evidence sufficient to warrant the theological propositions, even if they related to the commonest and most obvious everyday propositions.'

The question of evidence raises the whole issue as to the historical value of the gospel narrative (see GOSPELS). It is impossible, of course, to assume the infallibility of the record. The same scientific tests must be applied to the gospels as to any other historical narrative. Nor can it be assumed that every incident is equally well authenticated. The evidence for the healing miracles is infinitely stronger, for instance, than for the miracle of turning the water into wine at the marriage-feast at Cana, and that for the following reasons. (1) The latter is only found in our latest stratum of evidence, i.e. the fourth gospel, which was not written till seventy years after the event recorded is supposed to have happened. (2) The former appear in all the synoptics, and must, therefore, have come from the original sources out of which our present gospels are known to have been composed. (3) Numerous illustrations are given of the former class of miracles, while the latter stands alone, and is unique.

In weighing the evidence the ultimate question which we have to face is, Have we any first-hand testimony to the miracles in the New Testament? Now, such evidence cannot be obtained from the gospels, since neither Mark nor Luke was a disciple of Jesus; and the authorship of Matthew and John is a matter of dispute, and cannot be demonstrated beyond the possibility of doubt. But, none the less, it may be claimed that first-hand evidence is to be found in the New Testament. We have, firstly, two definite statements by Paul in his epistles. In Romans, xv. 18-19, he says: 'I will not dare to speak of any things save those which Christ wrought through me . . . in the power of signs and wonders;' and in 2 Corinthians, xii. 12, he makes a most explicit statement: 'Truly the signs of an apostle were wrought among you in all patience, by signs and wonders and mighty work.' There can be no doubt that these two statements represent the actual words of Paul, for they come from epistles the authenticity of which has never been challenged except by the Dutch school of criticism headed by van Manen, which is thoroughly discredited to-day. There is absolutely no doubt either that Paul definitely claims miraculous powers, because he uses the well-known technical expressions for miracle. Nor is it likely that Paul is making an unjustifiable claim, since he was surrounded by critics who would have been only too eager to pounce upon any untrue statement in his epistles. It may also be claimed that the account of Paul's healing of Publius' father in Malta rests upon first-hand evidence, since it occurs in one of the We-sections of Acts (xxviii. 7-10), and the writer was present on the occasion.

In the light of this evidence it seems to be quite clear that miracles were worked in the apostolic age, and, if this is so, there is a strong presumption in favour of the healing miracles in the gospel narrative. It must, however, be admitted that the account of many of them is affected by the mistaken belief which attributed most forms of disease to demonic possession (see section on Miracles in article on JESUS CHRIST).

The best modern books on Miracles are Bruce, *The Miraculous Elements in the Gospels*; Wendland, *Miracles and Christianity*; A. C. Headlam, *The Miracles of the New Testament*; Illingworth, *The Gospel Miracles*; J. M. Thompson, *Miracles in the New Testament*; E. O. Davies, *The Miracles of Jesus*; Mozley, *Eight Lectures on Miracles*; Bernard, article on 'Miracles' in *Hastings's Bible Dictionary*; Duke of Argyll, *The Reign of Law*; Newman, *Two Essays on Miracles*. On the negative side see Hume, *Enquiry Concerning the Human Understanding*, x.; Matthew Arnold, *Literature and Dogma*. See CANONISATION, STIGMATISATION, LOURDES, KNOCK, &c., also CONVULSIONARIES, SPIRITUALISM, CHRISTIAN SCIENCE, and on the evidences generally, APOLOGETICS.

Miracle Plays. See MYSTERIES.

Miræus, AUBERT (1573-1640), ecclesiastical historian, born at Brussels, educated at Douai and Louvain, was dean of Antwerp Cathedral from 1624. His larger works include a history of the Christian world, containing chronicles of Eusebius, St Jerome, and others (1608), a life of his teacher Justus Lipsius (1604), and books of ecclesiastical biography and geography.

Mirage. The density of the air generally diminishes with the height; rays of light proceeding obliquely upwards from an object then become more and more nearly horizontal, but generally pass away into space. Assume the density to diminish with the height with unusual rapidity, as when the air is cooler the nearer it is to the earth; the obliquely ascending rays may become quite horizontal and then bend down towards the earth, reaching it at a distant point. The observer at that point sees distant objects at an unusual

elevation, or sees above the true horizon erect images of objects which may or may not be beyond the horizon. This is what the sailors generally call looming, and it causes us sometimes to see distant coasts with unusual distinctness, or to see from a mountain top a double horizon, such as is regularly seen in the autumn mornings from the Colorado foot-hills across the prairies. If the layer of air near the earth, say 50 or 100 feet thick, be uniformly dense, as in the cold air over a frozen sea, and a warmer stratum lie above it in which the density rapidly diminishes, so that the rays are brought back to the earth as above, we find, on tracing the path of the rays reaching the observer from the top and the bottom of the distant object respectively, that these rays have crossed one another in the hot stratum; the observer therefore seems to see the object suspended in the air, magnified and upside down; and this may happen while the observer sees the object itself by direct vision through the lower air. An intermediate stratum between a cold ground-stratum and a warm upper stratum gives rise to more than one image, inverted or erect, or both, according to positions. In the mirage of the Sahara and other arid deserts the conditions are reversed; the air is hottest nearest the hot sand; skylight rays descending become bent upwards; the eye receives an impression resembling that produced by the reflection of skylight from water; the illusion is rendered more perfect by the flickering due to convection currents, which causes an appearance like a breeze playing over the illusory water.

The phenomena of mirage are frequently very strange and complicated, the images being often much distorted and magnified, and in some instances occurring at a considerable distance from the object, as in the case of a tower or church seen over the sea, or a vessel over dry land, &c. Looming is very frequently observed at sea, and a most remarkable case of this sort occurred on the 26th of July 1798, at Hastings. From this place the French coast is 50 miles distant; yet from the seaside the whole coast of France from Calais to near Dieppe was distinctly visible, and continued so for three hours. In the Arctic regions it is no uncommon occurrence for whale-fishers to discover the proximity of other ships by means of their images seen elevated in the air, though the ships themselves may be below the horizon. Generally, when the ship is above the horizon, only one image, and that inverted, is found; but when it is wholly or in great part below the horizon, double images, one erect and the other inverted, are frequently seen. The faithfulness and distinctness of these images at times may be imagined from the fact that Captain Scoresby, while cruising off the coast of Greenland in 1822, discovered the propinquity of his father's ship from its inverted image in the sky. Another remarkable instance of mirage occurred in May 1854, when from the deck of H.M. screw-steamer *Archer*, then cruising off Oesel, in the Baltic, the whole English fleet of nineteen sail, then nearly 30 miles distant, was seen as if suspended in the air upside down. Beside such phenomena as these, the celebrated *Fata Morgana* (q.v.) of the Straits of Messina sinks into insignificance. The *Spectre of the Brocken* is a magnified shadow of persons, &c., on the summit of the mountain, seen at sundown and sunrise thrown on mist banks on the side of the mountain opposite to the sun, with or without rainbow colours. This is rather a *glory* than a mirage proper (see HALOS). Its varieties are indeed numberless, and we refer those who wish for further information to Brewster's *Optics*, to Biot's *Traité de Physique*, and to R. W. Wood's *Physical Optics*, and for the mathematical theory of the mirage to

Tait on *Mirage*, *Trans. Roy. Soc. Edin.*, 1881. See also REFLECTION and REFRACTION.

Miraj, an Indian state in the southern Mahratta country. The capital, Miraj, near the Kistna River, has a pop. of 21,000.

Miramar, a palace standing on the rocky shore of the Adriatic near Grignano, 6 miles NW. of Trieste, was the home of Archduke Maximilian, afterwards Emperor of Mexico. See also MAJORCA.

Miramichi, the second river (220 miles) of New Brunswick, entering the Gulf of St Lawrence through Miramichi Bay, is navigable to 2 miles above Newcastle, the principal town on its banks.

Miranda, or SA DE MIRANDA, FRANCISCO DE (1495-1558), a Portuguese poet, founder of the school of which Camoens is the most brilliant representative. His earlier efforts were written in Spanish; his sonnets were the first written in Portuguese; his most characteristic works, his epistles in verse, are all in Portuguese but one. His works appeared at Lisbon in 1595: a better edition in 1614; a scholarly one, by Vasancellos, at Halle in 1885.

Mirbeau, OCTAVE (HENRI-MARIE), French writer, born in 1850 at Trévières (Calvados). Educated at Vannes, he entered upon a political career but turned to journalism, and, in the vein of Zola, wrote numerous novels and dramas. He died in Paris in 1917. Of his novels may be mentioned *Le Calvaire* (1886), *L'Abbé Jules* (1888), *Sébastien Roch* (1890), *Le Jardin des Supplices* (1898). His best drama, *Les Affaires sont les Affaires*, was written in 1903, and was adapted by Sydney Grundy.

Miran'dola, a town of Northern Italy, 19 miles by rail NNE. of Modena. It has a fine cathedral and an old castle. Pop. 20,000. See PICO.

Mirecourt, a town in the department of Vosges, 236 miles by rail ESE. of Paris, with manufactures of lace and musical instruments; pop. 6000.

Mirfield, a manufacturing town in the West Riding of Yorkshire, 3 miles W. by S. of Dewsbury, and $4\frac{1}{2}$ NE. of Huddersfield. It has a town-hall (1868), a parish church (restored 1871), and manufactures of woollen cloths, carpets, blankets, &c. Pop. 12,000.

Mirror, a reflecting surface, usually made of glass lined at the back with a brilliant metal, so as strongly to reflect the image of any object placed before it. When mirrors were invented is not known, but the use of a reflecting surface would become apparent to the first person who saw his own image reflected from water; and probably for ages after the civilisation of man commenced the still waters of ponds and lakes were the only mirrors; but we read in the Pentateuch of mirrors of brass being used by the Hebrews. Mirrors of bronze were in very common use amongst the ancient Egyptians, Greeks, and Romans, and many specimens are preserved in museums. Praxiteles taught the use of silver in the manufacture of mirrors in the year 328 B.C. Mirrors of glass were first made at Venice in 1300; and judging from those still in existence—of which one may be seen at Holyrood Palace, in the apartments of Queen Mary—they were very rude contrivances, in comparison with modern ones. It was not until 1673 that the making of mirrors was introduced into England. It is now a very important manufacture; and mirrors can be produced of any size to which plate-glass can be cast. In the old mercurial process, after the plate of glass was polished on both sides, it was laid on a perfectly level table of great strength and solidity, usually of smooth stone, made like a billiard-table with raised edges; a sheet or sheets of tinfoil sufficient to cover the upper surface of the glass were then put on, and

rubbed down smooth, after which the whole was covered with quicksilver, which immediately formed an amalgam with the tin. The superfluous mercury was then run off, a woollen cloth spread over the whole surface, and square iron weights applied. After a day and night weights and cloth were removed, and the glass removed to a wooden table, admitting of gradually increasing inclination until the unamalgamated quicksilver had perfectly drained away, and only the film of amalgam remained coating the glass, and perfectly adherent to it. Since the latter part of the 19th century, mirrors are usually made by silvering glass with an ammoniacal solution of a silver salt to which tartaric acid and sugar-candy have been added.

Heat is reflected like light; so that a concave mirror may be used to bring rays of heat to a focus. In this way combustible substances may be set on fire at a distance from the reflector whence they receive their heat. Thus used, a mirror is called a *Burning Mirror*.

The mirror is one of the most characteristic features of Japanese life and legend. It is usually of bronze, convex, polished by mercurial amalgam, and engraved on the back. In a few specimens the mirror may be used as a mirror in the ordinary way, but bright light reflected from its polished surface on to a screen gives bright-lined images corresponding to the figures on the back. This property of the so-called *Magic Mirror of Japan* is (according to Professors Ayrton and Perry) due to inequalities of curvature associated with inequalities of thickness, the thicker portions being the flatter.

Mirza (a contraction of *Emir Zadah*, 'son of the prince'), a Persian title, equivalent to 'Prince' when it follows the surname, and merely the common title of honour (like our 'Mr') when it is prefixed to it.

Mirzapur, a town and district in the United Provinces of British India. The town stands on the right bank of the Ganges, 45 miles by rail SW. of Benares. It has manufactures of shellac, carpets, brass-wares, and cotton-spinning. Pop. 55,000. The district has an area of 4368 sq. m., and a pop., almost all Hindus, of 724,000.

Miscarriage. See ABORTION.

Misdemeanour, in the law of England and Ireland, means a crime not involving forfeiture of property on conviction. Every crime is either treason, felony, or misdemeanour; and in creating new offences the legislature determines how they are to be classed. The distinction between felony and misdemeanour is not logically drawn, and it would disappear if the criminal law were codified on a rational plan. See Stephen's *Hist. of Crim. Law*.

Miseno, a promontory forming the western side of the Bay of Pozzuoli (*Sinus Cumanus*), 10 miles SW. of Naples. On it are ruins of the ancient city of Misenum, which Augustus made one of the principal stations of the Roman fleet.

Miserere, the name by which, in Catholic usage, the 50th Psalm of the Vulgate (51st in Authorised Version) is commonly known. It is one of the so-called 'Penitential Psalms,' which are said after Lauds on the Fridays in Lent, except Good Friday. It has been commonly understood to have been composed by David in the depth of his remorse for the double crime which the prophet Nathan rebuked in the well-known parable (2 Sam. xii.). Another opinion, however—plainly stated by Theodore of Mopsuestia (died 428), and adopted by many moderns—attributes this psalm to some of the psalm-writers of the Captivity; whilst others, again, hold that the last two verses only were added after the return from the Exile.

Miserere, a projection on the under side of the seats of the stalls of mediæval churches and chapels, &c. They are usually ornamented with

Miserere.

carved work, and are so shaped that when the seats proper are folded up they form a small seat at a higher level, sufficient to afford some support to a person resting upon it. Aged and infirm ecclesiastics were allowed to use these during long services.

Frate della Misericordia.

Misericordia, or MISERICORDE ('mercy'), a narrow-bladed dagger used by a knight in giving the *coup de grâce* or finishing stroke to a wounded foe.—Misericordia is also the name of a society (of laymen) in Florence, founded in the 13th century, who tend the poor sick, carry victims of accident or disease to the hospitals, and the dead to their burial. Members of all classes of the community, including the highest, are enrolled in this charitable institution; and their sombre and forbidding costume—a dark monastic dress, with the cowl pulled down over the face so that

the eyes merely peep through little holes—is not assumed because the Frati della Misericordia are penitents, but to check demonstrations of gratitude to the individual brethren.

Mishmee Bitter. See COPTIS.

Mishna (from Heb. *shana*, 'to learn'; erroneously held to designate Repetition) comprises the body of the 'Oral Law,' or the juridico-political, civil, and religious code of the Jews; and forms, as such, a kind of complement to the Mosaic or Written Law, which it explains, amplifies, and immutably fixes. It was not, however, on the authority of the schools and the masters alone that these explanations, and the new ordinances to which they gave rise, depended, but rather on certain distinct and well-authenticated traditions, traced to Mount Sinai itself. The Mishna (to which the Toseftas and Boraithas form supplements) was finally redacted, after some earlier incomplete collections, by Jehudah Hanassi, in 220 A.D., at Tiberias. It is mostly written in New Hebrew, and is divided into six portions (Sedarim): 1. Zeraim (Seeds), on Agriculture; 2. Moed (Feast), on the Sabbath, Festivals, and Fasts; 3. Nashim (Women),

on Marriage, Divorce, &c. (embracing also the laws on the Nazirship and Vows; 4. Nezikim (Damages), chiefly civil and penal law (also containing the ethical treatise Aboth); 5. Kadashim (Sacred Things), Sacrifices, &c.; description of the Temple of Jerusalem, &c.; 6. Taharoth (Purifications), on pure and impure things and persons. See also TALMUD.

Misiones, an Argentine territory, lies between the Uruguay and the Paraná, and is bounded on all sides but the SW. by Brazil and Paraguay. Area, 11,500 sq. m.; pop. 70,000—though before the expulsion of the Jesuits (1767) it exceeded 100,000. There are three low mountain-chains radiating from the centre. The greater portion of the surface is covered with forest, producing building and dye-woods, oranges, medicinal herbs, and *yerba maté*. Maize is largely grown, and sugar-cane to some extent. Capital, Posadas (pop. 16,000), on the Paraná.

Miskolcz, a town of Hungary, 113 miles by rail NE. of Budapest; pop. 57,000.

Mispickel. See ARSENOPYRITES.

Misprision. See TREASON.

Misrepresentation, a false statement affecting the validity of a contract or transfer of property. Wilful misrepresentation is the same as Fraud (q.v.). Innocent misrepresentation affects the formation of a contract in cases where one party has to rely on statements made by the other. An insurance company grants a policy in reliance on the statements made by the insured; a purchaser of land must rely on statements made by the vendor; an applicant for shares in a company relies on the truth of the prospectus. In these cases even unintentional misrepresentation will prevent the party responsible for it from enforcing the agreement against the party who had been misled. There are also cases in which a party is taken to warrant the truth of his statement; in these cases even an innocent misstatement may give the other party a right to be discharged altogether, or a right to claim damages for breach of warranty.

Missal, the volume containing the service of the Mass for the entire year. The name began to supersede the older word sacramentary from about the middle of the 8th century, but at first other books had to be used in conjunction, and the earliest missal complete in itself is not earlier in date than 900. Anciently missals differing in form were in use throughout the church, but with a view to restoring uniformity the pope, in virtue of a decree of the Council of Trent, in 1570 ordered that all churches should thenceforth adopt the Roman Missal, except such as had for a period of 200 years enjoyed an uninterrupted use of a service-book of their own. Under this exemption certain local missals continued to be used in England (the Sarum Missal), in France (the Gallican), in Germany, and even in Italy; but eventually the Roman form came almost universally to be adopted. Since 1570 the Roman Missal has been at various times revised—in 1604 by Clement VIII., in 1634 by Urban VIII., in 1884 by Leo XIII. It first appeared in printed form in 1474 at Milan. The missals of the oriental rites differ from that of the Roman Church, each having for the most part its own proper form.

Missions are organised efforts for the spread of a religion. Relative to the country conducting the work such efforts are characteristically undertaken abroad, and it is in the sense of foreign missions that the term missions is here employed. Christianity may be regarded as the typically missionary religion; but Buddhism, Mohammedanism, Zoroastrianism are also missionary faiths.

Christian Missions.—In the history of Christianity there have been but three distinctively

missionary periods: (a) the apostolic and immediately post-apostolic, (b) the mediæval, (c) the modern; between these times missionary activities have either ceased or been prosecuted without energy or discretion.

(a) *The Apostolic and immediately post-Apostolic Period.*—It is certain that Christianity made great progress during the lifetime of the apostles. From the 'Acts of the Apostles' it is manifest that within a few years of the resurrection of Christ the gospel obtained a footing in most countries to the east and the north of the Mediterranean; while from other authentic sources we learn that in the same brief period it was successfully introduced into Egypt and the other African regions on the southern shores of that sea. In contributing to this result, the labours of those Hellenistic Jews and proselytes of whose conversion to the faith we read in the second chapter of the Acts does not seem to have been sufficiently highly estimated. Of these Hellenistic Jews and proselytes three thousand were baptised. They had come from numerous Asiatic, African, and European lands and from the remote isles of the sea, and thenceforth they constituted a 'native agency' for conveying the message of the gospel into their several countries, and for telling of 'Jesus Christ and Him crucified' in the vernacular speech. But they needed training for this work, and remained for a time under the teaching and fellowship of the apostles. As the result of 'the persecution which arose about Stephen,' 'they were all scattered abroad, except the apostles,' and 'they that were scattered abroad went everywhere, preaching the word.' It must have been through the labours of these evangelists that Christian churches were founded in many places remote from Jerusalem—as, for example, at Damascus. In missionary zeal Paul has not been surpassed in any age, and his separation of Christianity from Judaism established the necessary pre-condition of all Christian missionary enterprise.

As to the personal labours of the apostles we have no reliable information outside the book of the Acts. There are innumerable churches that claim the honour of apostolic foundation; but their claims rest on traditions which cannot be traced beyond the 13th, the 12th, or, at most, the 11th century. There are, indeed, two exceptions—that relating to the foundation of a church in the kingdom of Edessa by Thaddæus, and that which ascribes the introduction of the gospel into India to the apostle Thomas. The authorities for these are apocryphal 'acts,' which are certainly of an early date, but which cannot be regarded as trustworthy documents. A greater amount of probability than is usually assigned to it appears to belong to the apostolic origin of the Syrian Church in southern India (see THOMAS, ST.).

We have no sufficient data from which to estimate the rate of the progress of Christianity during the apostolic age. From such data as are available statisticians have estimated the number of Christians existing at the death of the apostle John, or at the close of the first Christian century, at numbers varying from less than a quarter of a million to more than half a million. Whether within these figures or outwith them, the number was certainly large. The testimony of Tertullian to this effect would not be of much value if it stood alone. But from it, remarkably confirmed as it is by the unexceptionable testimony of the younger Pliny, it cannot but be inferred that within a century of the resurrection of Christ the gospel had been preached over a great part of the Roman world, and that at least in some provinces, as in Bithynia, it was threatening to supersede the worship of the gods of the empire.

(b) *The Mediæval Period.*—Apart from missions in the technical sense of the term, it is certain that various causes contributed to the wide diffusion of a knowledge of the gospel. Setting aside some altogether untrustworthy legends and traditions, we find no reason to believe that Christianity was first introduced into the British Islands by apostles or apostolic men, or by missionaries specially set apart for the work; and yet it is certain that before the time of Constantine there were churches of considerable extent both in the southern and the northern sections of Britain. The most probable supposition is that these churches owe their origin to the intercourse of Britain with Rome, which began with Cæsar's invasion, and soon attained large dimensions. Soldiers and civilians came from Rome to Britain, some of whom were Christians, while others brought with them Christian slaves. British merchants went to Rome as traders, British chieftains as diplomatists, British ladies as hostages. There is some reason to believe that one of the last class was a friend of Paul during his imprisonment there. But if the British Church did not owe its origin to missionaries in the strict sense of the term, it was destined to become the greatest missionary church throughout the earlier of the mediæval centuries. If Patrick really was a Briton, as seems demonstrable, he was the great leader of British missionary enterprise. He found Ireland entirely heathen, but he lived to see it professedly Christian, and a centre of scholarship not only for the neighbouring Britain, but also for the continent of Europe. The debt that Ireland owed to Scotland for the mission of Patrick she repaid a century later by the mission of Columba and his associates at Iona to the northern Picts and the Albanian Scots. If the Scottish Patrick might fitly be called the apostle of Ireland, and the Irish Columba in some sort the apostle of Scotland, Aidan, one of the Iona 'family,' is entitled in like sort to be regarded as the apostle of Northumbria; and St Cuthbert was a spiritual descendant of Aidan. Moreover, the Irish-Scottish missionaries were the great evangelists of a large part of the European continent. Ebrard has shown the magnitude and the importance of the work undertaken and accomplished by Columbanus and Gallus and a host of others, 'numerous as swarms of bees,' who, in the midst of countless difficulties, introduced agriculture and civilisation, learning and religion, into France and Switzerland and Italy and Germany, of which last country the English Boniface became the 'apostle.' Not that the externals of Christianity were non-existent at an earlier time. In France, for example, the Irish-Scottish missionaries had to do with the religion introduced by the Romans; but the pure faith was now represented by a corrupt clergy ministering to dissolute nobles and neglecting an enslaved people. They had to do also with the recent invaders, who were partly heathen and partly Arian, but it was less from these than from the orthodox that opposition was encountered.

What the Irish and Scots did for Europe in the earlier middle ages the Nestorians about the same time attempted, with no less zeal, though with less success, for Asia. Condemned as a heretic by a council held at Ephesus in the 5th century, Nestorius (q.v.) was banished from Constantinople to Egypt. From that time onwards, for five centuries, the Nestorians carried on extensive and not unsuccessful missionary operations in central Asia, and founded churches, some of which exist in a languishing condition to this day, whilst others recognised papal authority in the later mediæval centuries. The Nestorian Tatar Church seems to have subsisted under a succession of ecclesiastics (see PRESTER JOHN) until the country was de-

vastated by Genghis Khan. The Nestorians either introduced the gospel into India, or else revived a church previously founded, possibly by the apostle Thomas. There can be no reasonable doubt that in the 7th century they passed through Tartary into China, that they founded churches there, that they were at least tolerated and probably subsidised by successive emperors till the end of the 9th century, when, with a revolution or change of dynasty, the system of intolerance was introduced.

In the later mediæval centuries the missionary work was mainly in the hands of the great Roman orders, the Dominicans (q.v.) and the Franciscans (q.v.), especially the latter. Their work was chiefly among the Mussulmans of Spain, North Africa, and western Asia. Las Casas (q.v.) earned the title of 'apostle of the Indians.'

(c) *The Modern Period.*—The Jesuit order was formed immediately after the Reformation, avowedly for the purpose of retrieving the disaster which that great event had caused to the Church of Rome. By far the most distinguished of the early Jesuit missionaries was Francis Xavier (q.v.), who, essaying the conversion of the East, conducted great work in India, in the Malay Archipelago, and in Japan. After the labours of Ricci and Schall there are said to have been in China 300,000 Catholics in 1663. For the Jesuit 18th-century missions in Paraguay, see JESUITS, PARAGUAY. Notes on the Catholic missions in Japan and Korea will be found in the articles on these countries. There is a separate article on the Propaganda (q.v.). Since the Reformation 30,000,000 native converts are said to have been made by Roman Catholic missions, over 8,000,000 of these in the 19th century. Of the 19th-century converts over 6,000,000 are claimed for Asia, about 170,000 for Australia and Oceania, some 854,000 for Africa, and almost 1,000,000 for America.

The Reformation was a great preparation for missionary work, but the Reformation period was not distinctively a missionary period. In explanation it is to be noted that the Reformers' hands were full at home, and that the Protestant nations were lacking in the great colonial possessions of the Roman Catholic powers. Most important of all, however, was the interpretation placed by the Reformers on the Christian injunction to preach the gospel to every creature. When Luther has occasion to refer to that text, he tacitly assumes that its requirement is fulfilled when the *gospel*, as distinguished from Romanism, is preached to the nations of Europe. In the 16th and 17th centuries, therefore, we find no more than sporadic and ill-sustained efforts after mission-work, among the Jews and others. It fell to Leibniz, indeed, to anticipate the conception of a later age, and he may well be regarded as the harbinger of modern missions, even as, along with Newton, he is to be counted the harbinger of modern science. It was natural that the needs of the English colonies should first attract the interest of Englishmen to foreign parts; the life labours of John Eliot, 'the Indian apostle' (1604–90), were carried out under the auspices of the Corporation for the Spread of the Gospel in New England. The Hon. Robert Boyle, first governor of that society, contributed to the translation of the gospels into Malay, and left a bequest for foreign missions. Bishop Berkeley laboured for the foundation of a missionary college in Bermuda; and it was mainly for the spiritual wants of the American colonies that the Society for the Propagation of the Gospel in Foreign Parts was founded in 1701; its first missionary to India sailed in 1818.

Early in the 18th century the first Protestant mission was sent to India. It was projected

by the king of Denmark, having probably been suggested to him by his chaplain, Dr Lütkens. At first, and for a long time, Germany supplied the missionaries; but the pecuniary support of the mission soon devolved upon England, Prince George of Denmark, the husband of Queen Anne, having recommended the object to the Society for Promoting Christian Knowledge. Of all the men who have been engaged in this mission the most notable is Schwartz, who probably obtained an influence over all classes of the people of India such as no other European ever possessed.

While all the Protestant churches of Europe and America are now engaged in missionary work, there is one church which is distinguished from all the rest by this, that it is simply a missionary institute. Other churches make their missionary work subordinate to their pastoral functions; the Moravians or *Unitas Fratrum* have long regarded the conduct of missions as the end of their being. Beginning work in 1732, for its own sake and not as a part of colonial policy, their activities have extended from the West Indies and Greenland to the Tibetan Himalayas.

In England William Carey was the first effectually to arouse the missionary spirit of Protestantism, and he, too, was the first English Protestant personally to engage in missions. Finding his field in India, with his fellow-workers Marshman and Ward he established a centre in the Danish settlement of Serampore—the East India Company refusing countenance to any interference with native religion had barred him from British territory—and from there was laid the foundation for almost every method of subsequent missionary activity by the founding of schools and colleges, by the organising of native preachers and lay workers, but most of all by the publishing of Bible and other translations. It was in 1793 that Carey went to India. Henry Martyn's labours lay between 1805 and 1812. In 1795 the London Missionary Society was formed, and began its work by the despatch to the South Seas of the ship *Duff* with a large body of missionaries. For long the mission was not successful; but after a time it prospered greatly, and now there are many of the islands in which Christianity has for long been the sole religion. The London society cordially welcomed numerous fellow-labourers from England, Scotland, Germany, and America, and consented to a division of the islands for missionary purposes. It may be noted in passing that these small islands have contributed to a disproportional extent to the enrichment of missionary literature. Notable are Williams's *Missionary Enterprises*, Charlotte Yonge's life of Bishop Patteson, and Paton's narrative of his own work and that of his brethren in the New Hebrides.

The societies of the Church of England are the Society for the Propagation of the Gospel, High Church (1701), and the Church Missionary Society (1799). The English Nonconformists are represented in the mission-field all over the world by agents of the Baptist (1792), the London (1795), and the Wesleyan (1817) Missionary Societies. Among missionaries of the London Missionary Society have been Moffat and Livingstone. In the United States the American Board of Missions (1810) and the American Presbyterian Boards (North, 1837; South, 1862) are great organisations, whose agents are to be found in many fields; while the Baptists have their Burmese Mission (1813); the Methodist Episcopal Church Missionary Society came into the field in 1819. The efforts of the Salvation Army (q.v.) in the foreign field deserve mention. Missions to the Jews have a peculiar interest for many Christians. Zenana missions are a special department of Indian missions.

The Evangelical body in Germany is highly evangelistic in proportion to its strength. By means of many institutions it has trained and sent forth a large number of missionaries, some of whom have been men of extensive scholarship, but the greater proportion men of earnest piety. The Rationalistic party in Germany have not shown much zeal in the mission cause.

The Scottish missions differ from the others in this, that they are conducted by the churches as such, without the intervention of societies. The Church of Scotland and the United Free Church have extensive missions in India, Africa, China, the South Seas, and Japan. The English Presbyterian Church has an important mission in China. Notable among Presbyterian missionaries are Duff, Wilson, and Anderson in India, William Burns and Carstairs Douglas in China, Mary Slessor in Old Calabar.

Since the end of the 18th century 6,000,000 converts are said to have been made by Protestant missions.

The mode of carrying on missionary operations by the various bodies is essentially one, though, of course, modified by circumstances. In some cases 'medical missions' have come to be regarded as a valuable, and even as an indispensable, adjunct to other agencies. The missions of the Scottish churches have employed education as an evangelistic power to a greater extent than the other bodies, very widely in day schools, but also in such institutions as the Christian College at Madras, the mission station at Blantyre, and the United Free Church Institution at Lovedale in South Africa. Now, however, missions almost everywhere are confronted with expanding state systems of education, and in future missionary educational activities seem likely in many regions to be curtailed and even in some to be extinguished. In 1910 a Protestant World Missionary Conference was held in Edinburgh for the consideration along scientific lines of the problems of missionary enterprise, and here valuable reports which for two years previously had been prepared by representative commissions were presented.

The Orthodox Church accompanied Russian advances into Asia from the 16th century on; but its most notable work began in 1824 with the efforts of Archbishop Innocent (then known as John Veniaminov), who founded missions in Alaska and eastern Siberia. Others have worked among the Tatars, in China, and in Japan.

The Great War in certain of its reactions, most notably in its weakening of the moral and intellectual domination of western peoples, and in its intensification of national and racial antagonisms and suspicions, was unfavourable to the interests of Christian missions; and at the same time post-war political ferment in many parts of the world created missionary situations of peculiar difficulty.

Of the total population of the world it is estimated that under one-third is Christian. Whatever views, however, be held of the results of Christian proselytism, the great services rendered incidentally by Christian missions to literature, philology, exploration, anthropology, the study of comparative religion, and to the cause of civilisation in general are not to be forgotten.

Some account of Christian mission operations is given in the articles on the countries where these missions have had conspicuous success (FIJI, JAPAN, &c.); there are also biographical notices of the most eminent missionaries (ELIOT, CAREY, LIVINGSTONE, DUFF, HANNINGTON, XAVIER, RICCI, SCHALL, &c.). There is a bibliography (1913) by Weitbrecht, and one covering the period 1912-22 in *The International Review of Missions* (January 1922). Bliss, Dwight, and Tupper have edited *A New*

Encyclopædia of Missions (1905), and Dwight a *Blue Book of Missions* (1905, &c.). See also Henrion, *Histoire des Missions Catholiques* (1847); Spitz, *Les Missions Catholiques* (47 vols. 1868-1915); Louvet, *Les Missions Catholiques au XIX^e Siècle* (1894); J. S. Dennis, *Christian Missions and Social Progress* (3 vols. 1899-1906); A. Harnack, *Expansion of Christianity* (1904-5); Warneck, *Outlines of a History of Protestant Missions* (Eng. trans.; 3d ed. 1906); Streit, *Katholischen Missionsatlas* (1908); Fortescue, *The Lesser Eastern Churches* (1913); A. de W. Mason, *Outlines of Missionary History* (1913); C. H. Robinson, *History of Christian Missions* (1915); works by Marshall (1863), Rufus Anderson (New York, 1869), Christlieb (2d ed. 1880), Young (1881), William Brown (1882), P. Joung (New York, 1883), H. Gundert (2d ed. Calw, 1886), George Smith (1884; new ed. 1890), Stock (1904), Montgomery (1904), Bliss (1908), Ogilvie (1924); the reports (9 vols. 1910) of the World Missionary Conference, and the quarterly publication of its continuation committee, *The International Review of Missions* (1912, &c.). Statistics are to be found in numerous missionary year-books, in Dennis's *Centennial Survey of Foreign Missions* (1892), in Krose's *Katholische Missionsstatistik* (1908), and in a work (New York, 1916) by Beach and Burton St John.

Buddhist Missions.—Buddhist missionary enterprise outside India was initiated by Asoka (q.v.) in the latter half of the 3d century B.C., and in the centuries immediately following Buddhist missions seemingly spread themselves abroad in central Asia. In 67 A.D. Buddhism was first officially introduced into China, and there was eagerly received. Thereafter for a time the records of Buddhism in China are scant, but there is reason to suppose that the work of propaganda proceeded, though slowly. From the fall of the Han dynasty in 220 Buddhism enjoyed varying fortunes according to the differing faiths adopted by the several rulers of China. In the 4th century the greater part of the country began to be covered with Buddhist missions, and in the latter half of the 6th century Buddhism in China passes beyond the missionary stage. The translation into Chinese of Buddhist literature and the setting up of monastic institutions had been the outstanding features of the work, though it is not to be supposed that popular propaganda was wholly neglected. The borders of Tibet are said to have been touched by Asoka's missionaries, and in the 2d century A.D. a Buddhist temple is stated to have been built, but it is not till the 7th century that a footing can with certainty be held to have been obtained by Buddhism. Thereafter propaganda proceeded, but information as to its results is lacking, though here, as in China, the varying inclinations of successive rulers would appear again to have been the chief factor in determining the fortunes of the faith. With the later 10th century, however, came a fresh stream of Buddhist missionaries from North India; thereupon mystic Buddhism became more firmly established, and the missionary period of the religion, a period marked chiefly by literary activity, may be said to have ended. Towards the close of the 4th century Indian and Chinese missionaries first introduced Buddhism into Korea, but details as to their propaganda are wanting. In the course of about a century and a half, however, the whole country was converted to Buddhism. In Japan, Buddhism was first preached by Korean immigrants, and in 538 A.D. the religion was officially presented to the court. The fall of the conservative party in 587 was favourable to its advance, and in the reign (593-622) of Prince Shōtoku Buddhism became the state religion. Thereafter its progress was sure and steady, and before the close of the 8th century the whole country was converted to Buddhism. From the beginning of the 9th century Japan developed a Buddhism of its own, and from this time the missionary period

of Japanese Buddhism may be said to have ended, except for a new influx of Chinese influence in the latter half of the 13th century. Throughout, in marked contrast to the case of China, where an intellectual appeal had principally been made, propaganda had consisted chiefly in display of an elaborate ritual, in works of charity, especially medical works, though also to some extent in teaching, especially of science (astronomy, &c.). At the same time the missionaries also introduced skilled artisans and many useful arts, and did much for the economic advancement of the country.

See Nanjio, *A Catalogue of the Buddhist Tripitaka* (1883); *Nihongi* (trans. by Aston, 1896); Schlagintweit, *Buddhism in Tibet* (Leipzig, 1863); A. Lloyd, *The Creed of Half Japan* (1911).

Mohammedan Missions.—In the Koran the duty of missionary work is clearly laid down, and in a sense the missionary activity of Islam may be said to begin with Mohammed himself, who first sought converts in his own family, then in Mecca, and soon in Medina. Before his death in 633 Mohammed had extended his sway over the greater part of Arabia; but it was essentially a political sway, and religious converts were in a sense incidental. So later when Arab rule expanded over Syria, Persia, North Africa, and Spain, many converts were made, but there is no evidence of any distinctively proselytising effort; a notable exception, however, was 'Umayyad khalifah, 'Umar b. 'Abd al-'Aziz (717–20), who, in his vast dominions from North Africa to Transoxania and Sind, was a zealous propagandist. With the decline of the Arab empire the Moslem world was faced with the task of converting its new rulers. Obscurity surrounds the conversion of the Turks; but the work would seem to have proceeded slowly, and little headway was made before the 10th century, to which period also the winning of the Afghans is probably rightly to be assigned. In essaying the conversion of the Mongols in the face of competition from Buddhism and from Christianity a more formidable labour was undertaken. From the latter part of the 13th century, however, converts began to be made, and in Moslem missionary history a new epoch was inaugurated in which the religious orders and the Naqshbandi in particular played a prominent part. But in the Mongol empire the progress of Islam was essentially slow and fluctuating. In China Mohammedanism became firmly established in the 13th century through the influence of settlements of emigrants from the west; and these settlements subsequently developed through various causes, of which proselytism was one, into the great Chinese Moslem communities of modern times. In India from the beginning of the Mohammedan period a long series of preachers carried on a distinctively missionary work. In the 8th century a footing was gained in Sind and on the Malabar coast, and at the close of the 12th century in North India. Subsequently the flight to India of learned men and members of religious orders following the Mongol conquests of the 13th century resulted in a further spread of the faith. To its later extension various influences, political and social, no less than purposefully missionary, contributed. The introduction of Islam into the Malay Archipelago is traditionally ascribed to the 13th century. Sumatra, probably through the influence of traders, would seem to have been first affected, but the progress of the faith was slow. In the 15th century the conversion of Java was begun, and from thence Mohammedanism spread to the Moluccas and to Borneo; and in the 16th century, in the archipelago as a whole, Islam triumphed over Christianity. In the early days of Arab rule in Egypt and North Africa there

is little evidence of ordered missionary effort in the cause of Islam. Still, many converts were made, and by the 11th and 12th centuries Mohammedanism, by a process of gradual penetration, had acquired an ascendancy over the Berbers. Thereafter the Berbers introduced their adopted faith into the lands watered by the Senegal and the Niger, while Arabs from Egypt in the 12th century spread their religion into the Eastern Sudan. To the same period the conversion of Kordofan and Kanem would seem to belong. In the 13th century the Mandingoes emerge as zealous missionaries of Islam, to be followed by their converts the Hausas, destined later to spread their faith from one end to the other of the Sudan. Except in India and the Malay Archipelago there are few records of Moslem missions from the 15th to the 18th centuries. Nevertheless, in that period many conversions took place. Thus the Turkish conquests in Europe in the 14th and 15th centuries were followed by conversions to Islam on a large scale, and in the 17th century thousands of Christians in Turkey in Europe went over to the religion of their rulers; similarly the conquests of Ahmad Grān in Abyssinia (1528–43) were accompanied by numerous conversions. Speaking generally, however, these conversions were not the outcome of active propagandist effort. With the Wahhābi reformation, however, a great awakening took place in the missionary spirit of Islam, and the 19th century witnessed great missionary movements in India, in Sumatra, but especially in Africa, where later the partition of the greater part of the continent among the powers of Christian Europe gave an added stimulus to missionary effort, Moslem merchants and traders figuring in especial as proselytisers. While from the beginning Islam has always retained its primitive character as a missionary religion, it is remarkable that till the last decades of the 19th century societies for carrying on a continuous propaganda were unknown; such societies, too, when formed were largely in imitation of similar institutions in the Christian world. The most characteristic expression of the missionary spirit of Islam is to be found, indeed, not in permanent organisations, but in the proselytising zeal of the individual believer.

See T. W. Arnold, *The Preaching of Islam* (2d ed. 1913).

Zoroastrian Missions.—While the Iranism of ancient Persia was non-missionary, Zoroastrianism began as a distinctively missionary religion. Thus Zoroaster won King Vištāspa of Balkh to his doctrines, and he spread the faith with his conquests, amongst others to the Turanians. Zoroastrian missionaries, too, early disseminated the religion in distant lands, at times by invitation, though on occasion they encountered opposition. From the close of the Avestan period (224 A.D.) to the dynasty of the Sasanids (651 A.D.) there is an almost complete blank in the history of Zoroastrianism, though during this time there would seem to have been considerable diffusion, if not of orthodox Zoroastrianism, at least of Iranism, in Cappadocia, in Commagene, and in India. It was with the rise of the house of Sasan, however, that Zoroastrianism entered on its outstandingly missionary period. In many parts zealous proselytism was undertaken, and propaganda by force was even sanctioned in Persia and in Armenia. It was during this time also that there was some extension of Zoroastrianism in China, but this would seem to have been the result of commercial intercourse rather than of purposeful propaganda. With the Arab overthrow of the Sasanian dynasty the missionary enterprise of Zoroastrianism practically came to a close. True, the communities of Parsees

(q.v.), to which emigration had given rise in India, conducted some propaganda, but owing to the precariousness of their position only to a limited extent, though a measure of proselytism continued even as late as the 18th century.

See the article in the *Encyclopædia of Religion and Ethics*, and M. N. Dhalla, *Zoroastrian Theology* (New York, 1914).

Mississippi, one of the Gulf States of the American Union, lies west of Alabama and south of western Tennessee, and is bounded on the W. by the Mississippi River. Length, N. to S., 330 miles; width, 188 miles. Area, 46,865 sq. m. The surface except in the Yazoo delta, is generally hilly, though nowhere mountainous, the highest hills being only 800 feet above the sea-level. There are three distinct watersheds; the eastern counties are drained by the Tombigbee and its tributaries; the Pearl, Pascagoula, and Escatawpa with their affluents drain the central and south-eastern portion; and the Homochitto, Big Black, and Yazoo carry the water of the western and northern counties into the Mississippi. The Orange-sand formation (Post-Tertiary, 40 to 60 and even 200 feet thick) characterises the greater portion of the surface of the state, and forms the main body of the hills and ridges. It is usually coloured with hydrated peroxide of iron, or yellow ochre, and presents an endless variety of tints. Ferruginous sandstones, capping the tops of hills and thereby preventing denudation, are found in all sections covered by the Orange-sand formation. Gravel beds also abound, as well as beds of pipeclay, and of ochreous clays used for paints; and there are also vast beds of lignite of excellent quality, and marls which are used as ingredients of commercial fertilisers. There are mineral springs in different portions of the state.

Mississippi is essentially an agricultural state. The north-eastern prairie region, 70 miles long and from 15 to 20 wide, with its fertile, black, calcareous soil, contains much of the best farming and grazing land in the state. There are no springs here, but cisterns dug in the rotten limestone, bored wells, and artesian wells furnish ample water. In the north the bottom lands along the numerous creeks and rivers especially are well adapted to agriculture; while in the central portion stock-raising is carried on, and in the yellow-pine region large herds of sheep are raised. The yellow pine ranks first among the forest trees of Mississippi; it extends northward from the coast for 150 miles. The *Yazoo Delta*, embracing the elliptical area of alluvial bottoms between the Mississippi and Yazoo rivers, extending from Vicksburg to the state line on the north, is protected from inundation by levees. The delta's drainage flows into lakes, small but numerous, which form the head-waters of other bayous, and through them after miles of meandering find outlets into the Yazoo and other streams. The delta contains $4\frac{1}{2}$ millions of acres of alluvial land, of which about a third has been drained for cultivation. Virgin forests of hardwoods cover the rest. The majority of the farmers are coloured. Cotton is the chief crop. Others are corn, rice, wheat, oats, hay, and nuts.

The winters in Mississippi are short and mild, the mean temperature 45° F.; the summers are devoid of intense heat, the mean 81° , seldom reaching 100° . Ice from one to two inches thick forms in the northern part of the state. The elevation of the surface and the Gulf breezes render the climate delightful during most of the year. The annual rainfall ranges from 48 to 58 inches. The death-rate is very low— $12\cdot9$ in 1000.

Mississippi sends two senators and eight representatives to congress. The state legislature is elected quadrennially. Separate schools are main-

tained for the coloured race, who form more than half the population. The illiteracy rate is high, but falling. Of some twenty colleges for higher education the most important is the University of Mississippi at Oxford (1844). Institutions for the deaf and dumb and the blind are at Jackson, the capital; there also is the state penitentiary. There are about 4400 miles of railway in the state. Vicksburg, Greenville, and Natchez are principal ports on the Mississippi River, and Pascagoula and Biloxi on the Gulf. Manufactures (especially timber products, cotton-seed oil and cake, cotton goods) are growing. Mississippi is not a mining state. Pop. (1820) 75,448; (1880) 1,131,597; (1900) 1,551,270; (1910) 1,797,114; (1920) 1,790,618.

History.—Mississippi was first settled by the French, and constituted a part of Louisiana. Iberville planted the first colony at Biloxi in 1699. It was ceded to Great Britain in 1763; was admitted into the Union as a state, 10th December 1817; seceded 9th January 1861 (principal battles during the civil war, Corinth, Baker's Creek, Holly Spring, Iuka, siege of Vicksburg); was readmitted into the Union, 1869.

Mississippi - Missouri. The Mississippi River (Algonkin *Missi Sipi*, 'Great River'; literally 'Father of Waters'), the largest river of the North American continent, is, with its tributaries, wholly within the boundaries of the United States. It drains most of the territory between the Rocky and Alleghany Mountains, embracing an area of 1,257,545 sq. m., or more than two-fifths of the area of the United States. This basin includes the minor basins: Lower Mississippi, 65,646 sq. m.; Red River, 92,721; Arkansas, 184,742; Missouri, 527,690; Upper Mississippi, 179,635; Ohio, 207,111. Besides the four tributaries here named, there are forty-one others navigable, and 200 more of moderate size. The total length of the Mississippi is 2960 miles, of which 2161 are navigable; but the Missouri affluent (see below) is longer than the Upper Mississippi, and with the lower river gives a total of 4200 miles. The total navigable waters amount to 16,090 miles.

The source of the Mississippi is Lake Itasca in the north-west central part of Minnesota, about 7 miles long by 1 to 3 wide, which has, however, several feeders, the principal being Elk or Glazier Lake. The remotest springs of Itasca rise in $47^{\circ} 34'$ N. lat. and $95^{\circ} 20'$ W. long., and are 1680 feet above sea-level. As it issues from this lake the Mississippi is about 12 feet wide and 18 inches deep. Through pine-forests and swamps for hundreds of miles it winds from lake to lake, with frequent rapids and picturesque falls, until, 1200 feet wide, at the city of Minneapolis it plunges over the Falls of St Anthony. This point is the head of river-navigation, though in various reaches above small steamboats ply. After receiving the St Croix, the Mississippi becomes the boundary between the states of Minnesota, Iowa, Missouri, Arkansas, and Louisiana on the right, and Wisconsin, Illinois, Kentucky, Tennessee, and Mississippi on the left. Its frequent rapids within Minnesota are due to the granite bed, but sandstone prevails farther down, to Rock Island, Illinois. On the Wisconsin boundary the river expands into Lake Pepin, and thereafter, fully a mile wide, flows between bluffs 200 and 300 feet high, and sometimes through dense forests. At Rock Island there are rapids with 22 feet of fall, and 125 miles farther down are the Des Moines rapids with 24 feet of fall. Around these obstructions to navigation the United States government has constructed ship-canals. The entrance of the turbid Missouri produces a marked change in the character of the river; for several miles the diverse waters refuse to mingle, the Missouri's muddy

tribute taking the right bank and the Upper Mississippi's clear stream the left. When the union is complete, the whole river has thenceforth a light yellowish colour, modified somewhat by the Ohio's greenish water and more by the reddish water of the Arkansas and Red. From the mouth of the Ohio the trough of the Mississippi is about 4470 feet wide, but as it approaches the Red it is narrowed to 3000 feet, and at New Orleans is 2500 feet. The usual depth of the channel southward from the Ohio is from 75 to 100 feet, and its surface is sometimes higher than the country beyond its banks. In fact, from the Missouri to the Gulf the Mississippi rolls in serpentine course through vast alluvial tracts or 'bottoms,' whose width varies from 30 to 150 miles. The melting of the ice and snow in the upper basin swells the lower current from March to June. Levees or embankments, largely built by the government, now extend for more than 2000 miles. Between the Ohio and the Red rivers extraordinary floods, rising from 47 to 51 feet, occur about once in ten years, making 'crevasses' in the levees, and doing immense damage. In these great floods the river has been known to spread over a tract of 150 miles. Beyond the Red River the waters are discharged through numerous 'bayous' into the Gulf of Mexico. The main channel runs south-eastward, and finally divides into five or six passes, the principal being the south, the north-east, and the south-west; the last is in 28° 58' 5" N. lat. and 89° 10' W. long.

The mean velocity of the Lower Mississippi is $2\frac{1}{2}$ miles per hour. The yearly discharge into the Gulf is nearly 145 cubic miles; the sedimentary matter carried with this would form a prism 1 mile square and 263 feet high, while the amount pushed along the bottom of the channel would make another 1 mile square and 27 feet high. These vast deposits and the constant changes caused by floods tend to embarrass the entrance to the great river. To keep an open channel, at least 20 feet deep, Captain Eads contracted with the United States government to erect and maintain a system of jetties at the South Pass. The construction was begun in 1875, and has proved highly successful, a depth exceeding 30 feet having been maintained. The mouth of the Mississippi is essentially tideless.

The principal cities on the great river are Minneapolis, St Paul, La Crosse, Dubuque, Keokuk, Quincy, Hannibal, St Louis, Memphis, and New Orleans, at several of which the river is crossed by railway bridges. The steel bridge at St Louis is the most southern, besides which another was connected at the same city in 1890.

MISSOURI RIVER ('Big Muddy'), the principal branch of the Mississippi River, is formed by the confluence of the Jefferson, Gallatin, and Madison rivers, at Gallatin City, Montana, 4132 feet above the sea-level. These rivers rise in the Rocky Mountains, close to the sources of the Columbia and Colorado rivers, and to the Continental Divide. The Madison has the remotest source in a small lake of the same name in Yellowstone National Park in Wyoming, 44° 19' N. lat. and 110° 50' W. long., at an elevation of 7632 feet. This river flows north-west and north to the junction of the Three Forks. The Missouri then flows northward, skirting the main range of the Rocky Mountains, and, after passing through a gorge called 'The Gate of the Mountains,' turns to the north-east and reaches Fort Benton, the head of navigation, 225 miles from Gallatin City. About 40 miles above Fort Benton are the Great Falls, where the river descends 327 feet in 15 miles by a series of cataracts, the highest having a perpendicular fall of 87 feet. From Fort Benton the course is easterly, the river being flanked by bluffs about a mile apart

until it passes the rapids 400 miles below, when the valley opens to a width of 10 miles. The Milk River is its first large tributary, but at the boundary of North Dakota the still larger Yellowstone joins it. The Yellowstone also rises in the National Park, and flows at first over cataracts and through cañons until it emerges in a more level country. It is 1152 miles long, and has the general characteristics of the Missouri. From its junction, which is the head of navigation in the low-water season, the Missouri flows through North Dakota, east and then south-east to Bismarck (1610 feet above sea-level), where it is crossed by the splendid bridge of the Northern Pacific Railroad. Through South Dakota the south-easterly course continues to Sioux City, whence flowing south the river becomes the boundary between Nebraska and Kansas on the right and Iowa and Missouri on the left. On receiving the tributary Kansas the stream turns to the east, and flowing across the state of Missouri pours its muddy waters into the channel of the Mississippi, 20 miles above St Louis. The Missouri is 3047 miles long, of which 2682 are called navigable, but owing to its tortuous, treacherous, and obstructed channel navigation is attended with great risks. The growing cities on its banks forsake the use of the river for commercial purposes and depend on the railways. In 1866 there were seventy-one steamers in active service in that part within the state of Missouri, but twenty years later the number had diminished to seven steamers and three tow-boats. The chief towns on the banks are Bismarck, Yankton, Sioux City, Omaha, Council Bluffs, Nebraska City, St Joseph, Atchison, Leavenworth, and Kansas City.

Mississippi Scheme, projected in France by John Law (q.v.) of Lauriston in 1717, proposed to develop the resources of the province of Louisiana and the country bordering on the Mississippi. The company, incorporated as *Compagnie des Indes Occidentales*, started with a capital of 200,000 shares, of 500 livres each. Shares were eagerly bought; and when, in 1719, the company obtained the monopoly of trading to the East Indies, China, the South Seas, and all the possessions of the French East India Company, the brilliant vision opened up to the public gaze was irresistible. The *Compagnie des Indes*, as it was now called, created 50,000 additional shares, but a rage for speculation had seized all classes, and there were at least 300,000 applicants for the new shares, which consequently went up to an enormous premium. The public enthusiasm now rose to absolute frenzy, and Law's house and the street in front of it were daily crowded with applicants of both sexes and of all ranks; and while confidence lasted a factitious impulse was given to trade in Paris. But the regent had meanwhile caused the paper circulation of the national bank to be increased as the Mississippi stock rose in value, and many wary speculators, foreseeing a crisis, had secretly converted their paper and shares into gold, which they transmitted to England or Belgium for security. The increasing scarcity of gold and silver becoming felt, a general run was made on the bank. The Mississippi stock now fell considerably, and despite sundry desperate efforts, which were attended with momentary success, to keep up its credit, it continued to fall steadily and rapidly. In February 1720 the National Bank and the *Compagnie des Indes* were amalgamated, but, though this gave an upward turn to the share-market, it failed to put the public credit on a sound basis. Several useless attempts were made by Law, now controller-general of the finances, to mend matters; and those suspected of having more than a limited amount (fixed by a law passed at the time) of gold and silver in their possession, or of having removed

it from the country, were punished with the utmost rigour. The crisis came at last. In July 1720 the bank stopped payment, and Law was compelled to flee the country. A share in the Mississippi Scheme now with difficulty brought twenty-four livres. An examination into the state of the accounts of the company was ordered by government; much of the paper in circulation was cancelled; and the rest was converted into 'rentes' at an enormous sacrifice. See LAW (JOHN), and books there cited.

Missive, in Scots law, is a memorandum.

Missolonghi (*Mesolongion*), a seaport town of Greece, in the nomarchy of Ætolia, on the northern shore of the Gulf of Patras, 24 miles W. of Lepanto. A modern place, built on a swampy flat, it is chiefly memorable for the two sieges which it underwent during the war of independence. In 1821-22 it was vainly invested for three months by land and sea by the Turks; in 1825-26 it was again besieged by an overwhelming Ottoman force, and, after ten months of resistance and suffering, its garrison, reduced from 5000 to 3000 fighting-men, cut their way through the ranks of the enemy, carrying with them a great number of the women and children. The Turks then entered the town, which was all but totally destroyed. There is a statue (1835) over the grave of Bozzaris, and another (1881) of Lord Byron, on the spot where his heart is interred. Pop. 8000.

Missouri, one of the central states of the American Union, and ninth in order of population, is midway between the Rocky Mountains and the Atlantic; and, lying between 36° and 40° 30' N. lat. and between 89° 2' and 95° 51' W. long., occupies a commanding position in the Mississippi valley. It is 280 miles long from north to south, and gradually increases in width from 208 miles in the north to 312 miles in the south. Area, 69,420 sq. m., or nearly that of Scotland, Ireland, and Wales. The Missouri River divides the state into two unequal sections, designated 'North Missouri' and 'South Missouri' respectively. That part of the state lying north of the Missouri River is generally level or slightly undulating, consisting of rolling prairies and level bottom lands, diversified with a luxuriant growth of timber along the streams. The southern section has a more diversified surface, deriving its distinctive features from the Ozark Mountains, which cover about one-half of this division. These mountains enter the state from north-western Arkansas, and extend across the state to the Mississippi River; throughout the greater part of their length they may very properly be classed as tablelands, reaching their highest altitude (1500 feet) in Greene and Webster counties, and gradually breaking up into narrow ridges, spurs, knobs, and peaks farther east. The entire eastern limit of the state is washed by the Mississippi River, with a water front of 560 miles, while the Missouri River forms the boundary from the extreme north-west corner to Kansas City, and thence across the state to the Mississippi, with which it unites just above St. Louis. Many smaller tributaries flow into these two majestic rivers—into the Mississippi the Fabius, Salt, Cuivre, Meramec, St. Francis, Current, and Black; and into the Missouri the Nodaway, Platte, Grand, and Chariton on the north, and the Osage and Gasconade on the south. The general drainage of the surface is indicated by long gentle slopes toward the Mississippi and Missouri rivers, except in the extreme south-west, where the streams flow into the Arkansas. The climate is genial, agreeable, and healthful. All the extremes of heat and cold peculiar to this latitude are experienced; but

the mean annual temperature is about 54°, and the mean average rainfall is 41 inches.

Missouri is pre-eminently an agricultural state. Of the 44,000,000 acres of her land surface more than 42,000,000 are adapted to agricultural and horticultural purposes. The soils are rich, deep, and unsurpassed in variety and productiveness. The principal crops are Indian corn, hay, wheat, oats, potatoes, rye, barley, hemp, flax, cotton, sorghum, and buckwheat. Of tobacco a fair crop is 8,000,000 lb.; and orchard products are grown in great abundance. There has been a great increase in the number of grazing animals, especially mules and horses. The immense quantities of dressed beef and pork shipped annually to home and foreign markets are constantly increasing.

The mineral resources of Missouri are exceedingly rich, comprising extensive coalfields, that cover more than 20,000 sq. m.; also vast deposits of iron ore, lead, and zinc; while copper, cobalt, nickel, fireclays, fine marble, granite, and limestone of excellent quality abound in different localities. The coalfields are capable of yielding 100,000 tons of bituminous coal a day for several thousand years. The supply of iron ore is excellent in quality and inexhaustible in quantity; but the richest deposits yet worked are confined chiefly to two counties in the south-east—Iron and St. François. Yet the iron belt south of the Missouri River, and extending from the Mississippi River on the east to Osage River on the west, covers an area of 25,000 sq. m. Excellent transportation facilities are afforded by the Mississippi River along the eastern border of the state, and by the Missouri River across the state; and the railroads are about 9000 miles in length.

Missouri returns two senators and 16 representatives to congress. The general assembly (34 state senators and 142 representatives) meets every two years. The public-school system is very complete and very efficient, embracing the state university, the school of mines, state normal schools, and city, town, village, and country schools. Washington and St. Louis (Roman Catholic) Universities are at St. Louis.

The metropolis of Missouri is St. Louis (pop. 1920, 772,897), one of the greatest railroad, manufacturing, and commercial centres in the country; Kansas City (324,410), St. Joseph, Springfield, Joplin, Hannibal, Sedalia, Chillicothe, Mexico, Moberly, Boonville, Nevada, Marshall, Kirksville, Carrollton, Lexington, &c., are all thriving cities. Pop. (1820) 20,845; (1840) 140,455; (1860) 1,182,012; (1880) 2,168,380; (1900) 3,106,665; (1910) 3,293,335; (1920) 3,404,055.

History.—Missouri was first explored by De Soto in 1541-42, and in 1673 Marquette and his followers visited its eastern border. It formed part of the 'Louisiana Purchase' (see LOUISIANA), the northern portion of which in 1805 was organised as the 'District of Louisiana.' It was not till 1812 that a part of this territory took the name of Missouri. In 1821 Missouri was admitted into the Union, but the present limits of the state were not established till 1836. Its admission was preceded by a long and bitter political controversy between the representatives of the North and South, the former resisting its entrance as a slave-state. The discussion resulted in the famous 'Missouri Compromise,' under which compact it was agreed that slavery should be for ever excluded from all that part of Louisiana north of 36° 30' lat., except Missouri. During the four years of the great civil war the citizens of Missouri suffered terribly. The people were nearly equally divided in sentiment, and both sides prepared for the conflict. The state furnished 109,111 men for the Union army, and about three-fourths as many for the other

side. Death and the destruction of property everywhere prevailed. But when the war ended the people commenced to build up the waste places; improvements were extended in all directions, bitter feelings soon died away, and the state entered upon an era of singular prosperity.

Missouri River. See MISSISSIPPI-MISSOURI.

Mist. See FOG.

Mistassini, LAKE, in Labrador, some 300 miles N. by W. of Quebec, is strictly speaking an expansion of the river Rupert, which flows into the southern extremity of Hudson Bay. It is 100 miles long from north-east to south-west by 12 in average breadth.

Mistletoe, with its thick, succulent, yellowish foliage, and white, viscous berries, was long a puzzle to botanists, its peculiar mode of growth having given rise to the most curious fancies. The name is shared by several genera of Lorantheæ (*Viscum*, *Loranthus*, and the Australian *Notothixos*), with about 600 species. The only British species of these parasitical shrubs is the Common Mistletoe (*Viscum album*), a native also of the greater part of Europe (not of north England, Scotland, or Ireland), growing on many kinds of trees, particularly on the apple and others botanically allied to it, as the pear, service, and hawthorn; sometimes, also, on sycamores, limes, poplars, locust-trees, and firs, but very rarely on oaks (contrary to the common belief). In the Himalayas the mistletoe grows abundantly on the apricot-tree, on the vine and *loranthus* in Italy, on spruce-firs in France and Switzerland. The evergreen leaves of the *V. album* of English woods, with their yellowish hue, make a conspicuous appearance in winter among the naked branches of the trees. The flowers are insignificant, and grow in small heads at the ends and in the divisions of the branches, the male and female blossoms on separate plants. The berries are about the size of currants, white, translucent, and full of a very viscid juice, which serves to attach the seeds to branches, where they take root when they germinate, the radicle always turning towards the branch, whether on its

Mistletoe (*Viscum album*).

upper or under side. It may be easily made to grow on suitable trees even where not native—as in Scotland, for example.

The mistletoe was intimately connected with many of the superstitions of the ancient Germans and of the British Druids. In the northern mythology, Balder (q.v.) is said to have been slain with a spear of mistletoe; and in Holstein it is the *Märentaken*, or 'branch of spectres,' which confers upon its possessor the power to see ghosts. Among the Celts the mistletoe which grew on the oak was in peculiar esteem for magical virtues. According to an old tradition the mistletoe supplied the wood for the cross, which until the

time of the crucifixion had been a forest tree, but was henceforth condemned to exist only as a mere parasite. Traces of the ancient regard for the mistletoe still remain in some old English Christmas customs, as kissing under the mistletoe. The mysterious surrounding of the mistletoe invested it with a widespread importance in old folklore remedies. Culpepper speaks of it as 'good for the grief of the sinew, itch, sores, and toothache, the biting of mad dogs and venomous beasts;,' while Sir Thomas Browne alludes to its virtues in the cure of epilepsy. In Sweden a finger-ring made of the mistletoe is an antidote against sickness, and in France amulets made of its wood were formerly much worn.—*Loranthus europæus*, a shrub very similar to *Viscum album*, but with flowers in racemes, is plentiful in some parts of the south of Europe, and very frequently grows on oaks.—*L. odoratus*, a Nepalese species, has very fragrant flowers.—The American mistletoe, *Phoradendron*, of which there are some eighty species, is similar in general appearance and habit to the European. The commonest species is *P. flavescens*, found from New Jersey to Mexico.—The West Australian *Nuytsia floribunda*, a tree of 30 to 40 feet, seems to be parasitic on roots.

Mistral (also *Mistraou* and *Maestral*), a north-west wind which at certain seasons of the year prevails on the south coast of France. Its approach is heralded by a sudden change of the temperature, from the most genial warmth to piercing cold; the air is felt to be purer, and more easily inhaled, the azure of the sky is undimmed by cloud, and the stars shine by night with extraordinary and sparkling brightness. The mistral then comes in sudden gusts, struggling with the local aerial currents, but its fast-increasing violence soon overcomes all opposition. In a few hours it has dried up the soil, dispersed the vapours of the atmosphere, and raised a dangerous tumult among the waters of the Mediterranean. The mistral blows, at intervals, with its greatest force from the end of autumn to the beginning of spring.

Mistral, FRÉDÉRIC (1830–1914), Provençal poet, was born a peasant's son near Maillane (dept. Bouches-du-Rhône), and studied law at Avignon; but for law he had no liking, and he went home to work on the land and write poetry. In 1859 he published the epic *Mirèio* (Eng. trans. 1890), written in his native Provençal dialect. This charming representation of life in southern France made Mistral's name famous throughout the country, and gained for him the poet's prize of the French Academy and the cross of the Legion of Honour. It also led to the formation of the society called *Lou Felibrige*, which set itself to create a modern Provençal literature. In 1867 Mistral published a second epic, *Calendau*, and in 1876 a volume of poems entitled *Lis Isclo d'Or* ('Golden Islands'), songs steeped in the golden sunshine of the Mediterranean and its vine-clad shores. He also published a novel in verse, *Nerto* (1884), a Provençal dictionary (1878–86), and *Mes Origines* (1906). There are verse translations by Mrs Preston and H. Crichton. See books by Downer (1901), Kiepert (1905), and Schoen (1910).

Mistretta, a town of Sicily, near the north coast, half-way between Palermo and Messina; pop. 12,000.

Mitanni, an ancient kingdom lying to the east of the upper Euphrates in the region of the rivers Khabur and Belikh. By the middle of the second millennium B.C. a group of warriors of Iran had pushed westwards into Mesopotamia and established an Aryan dynasty ruling the kingdom of Mitanni. Thereafter the kingdom grew at the

expense of its neighbours Alshe and Assyria into a powerful and cultivated state, whose influence and language extended westward to Tunip in the Orontes valley, and eastward to Nineveh. Its capital was Washshukkani. Through the campaigns of the Egyptian rulers Thutmose I. (acceded 1540 B.C.), Thutmose III. (acceded 1501 B.C.), and Amenhotep II. (acceded 1447 B.C.) contact with Egypt was established, and the marriage relationships entered into on a footing of equality between the two countries at the end of the 15th century, when the power of Egypt was at its height, are evidence of the importance of Mitanni. After about 1375 B.C., however, strong anti-Egyptian movements gained ground in Mitanni and elsewhere in north-western Asia, and the power of the country declined, its name disappearing from history. Knowledge of the Mitannians is limited, the archaeological evidence being both slight and uncertain. Their racial affinities are said to be with the Hittites. About a thousand clay tablets in Assyrian from a house conjectured to have been that of a Mitannian were discovered in 1924-25 by Dr Chiera at Yaghlan Tepe, 8 miles SW. of Kirkuk; of the proper names there are about one hundred Aryan to every one Semitic. While the ruling dynasty of Mitanni was Indo-European, the prevailing language, an example of which in cuneiform survives in a long Amarna letter, is not Indo-European, but according to most philologists akin to Georgian; some say it is allied to Hittite, itself a tongue of unknown origin. The name Mitanni may survive in the modern Metina, the designation of a mountainous district a day's march north-west from Mardin.

Mitau (Lettish *Jelgava*), a town of Latvia, till 1918 capital of the Russian government of Courland, on the right bank of the Aa, 27 miles by rail SW. of Riga. Founded in 1271 by the grand-master of the Teutonic Knights, and annexed to Russia in 1795, it has a castle, begun by Biron in 1738, a museum, &c., with some very important manufactures (flax, iron, leather, ink), and a trade in grain and timber. From 1798 to 1807 Mitau offered an asylum to Louis XVIII. Pop. 25,000, of whom more than one-half are Germans, and nearly a fourth Jews.

Mitcham, a village of Surrey, forms a ward of Croydon. It lies in the centre of a district in which flowers and aromatic herbs (roses, lavender, camomile, &c.) are extensively grown.

Mitchel, JOHN, an Irish patriot, was born the son of a Presbyterian minister at Dungiven in County Derry, 3d November 1815. He studied at Trinity College, Dublin, and practised several years as an attorney at Banbridge. Soon after the formation of the Young Ireland party, and the starting of the *Nation* in 1842, Mitchel began to contribute, and after the death of Thomas Davis in 1845 he became assistant-editor. But his language was too violent for the paper, and three years later he started the *United Irishman*, for his articles in which he was tried on a charge of 'treason-felony' and sentenced to fourteen years' transportation. He was sent to Bermuda, and next to Van Diemen's Land, whence he made his escape to the United States in the summer of 1853. In New York he published his *Jail Journal, or Five Years in British Prisons* (1854). Next followed a series of short-lived newspapers, the *Citizen*, the *Southern Citizen*, the *Richmond Inquirer*, and the *Irish Citizen*, which cost him the confidence of many of his American friends by its enthusiastic defence of slavery and the South. In 1874 he returned unmolested to Ireland, and was elected to parliament for Tipperary, but declared ineligible. Again elected, he died at Cork, 20th March 1875.

Of his books may be mentioned a *Life of Hugh O'Neill, Prince of Ulster* (1845); and *History of Ireland from the Treaty of Limerick* (1868); besides editions of the poems of Thomas Davis (1856) and James C. Mangan (1859). See the studies by William Dillon (2 vols. 1888), Montégut (trans. 1915), O'Hegarty (1917).

Mitchell, DONALD GRANT, an American author, many of whose works appeared under the pen-name of 'Ik Marvel,' was born in Norwich, Connecticut, 12th April 1822, was in 1853 appointed consul at Venice, in 1868-69 editor of the *Atlantic Monthly*, and died 15th December 1908. About his farm—Edgewood—near New Haven, he wrote several delightful books. Among his other works are *Reveries of a Bachelor* and *Dream Life* (1850-51; new eds. 1889); a novel, *Dr Johns* (1866); *English Lands, Letters, and Kings* (1889); *American Lands and Letters* (1897-99).

Mite. See ACARINA, CHEESE-MITE, ITCH, HARVEST-MITES.

Mitford, MARY RUSSELL, born at Alresford, Hants, 16th December 1787, was the only child of a physician, a selfish, extravagant man, who spent several fortunes, and was always in debt. A few years after his marriage he moved to Lyme Regis, and thence to London. On Mary's tenth birthday he took her to a lottery office, and bought her a ticket. She chose a particular number which drew a prize of £20,000. While this money lasted she was sent to a good school in Chelsea, and Dr Mitford built himself a large house near Reading. Here Mary returned when she was fifteen, a clever, accomplished girl, devoted to her parents, a great reader, and fond of gardening. Her first volume of poems appeared in 1810, and was followed in 1811 and 1812 by two other poems. In 1820, as the family became more and more impoverished, they were obliged to move to a cottage at Three Mile Cross, near Reading, and at length the need came for Miss Mitford to write to earn money. She wrote for magazines, and plays for the stage. Four of her tragedies, *Julian*, *The Foscari*, *Rienzi*, and *Charles I.*, were acted; the three first met with success, but they have not kept the stage. Her true line was describing what she saw around her in a series of sketches of country manners, scenery, and character. These little essays were rejected by several London editors, but at length found a place in the *London Magazine*, and were published in a collected form in 1824 under the name of *Our Village*, the series of five volumes being completed in 1832. Few would think, as they read this 'playful prose,' with what toil and anxiety it was written. Dr Mitford died in 1842, leaving his affairs in such a state that a subscription was started to enable his daughter to pay his debts; which was soon followed by a pension from the crown. In 1851 Miss Mitford moved to a cottage in Swallowfield, a village close by, where she spent the rest of her life. In 1852 she published *Recollections of a Literary Life*, and in 1854 a novel, *Atherton, and other Tales*. She died 10th January 1855, and was buried at Swallowfield. Her sketches are charming. See *Life by L'Estrange* (3 vols. 1878), and his *Friendships of Mary Russell Mitford* (1882).

Mitford, WILLIAM, was born in London, 10th February 1744, entered Queen's College, Oxford, but left without a degree. In 1761 he succeeded to the family estate of Exbury near the New Forest, and in 1769 became a captain in the South Hampshire Militia, of which Gibbon was then major. By Gibbon's advice and encouragement he was induced to undertake his *History of Greece* (5 vols. 1784-1818). It is a pugnacious, opinionative, one-sided, and even fanatical production. The author is an intense hater of democracy, and can see in Philip of Macedon nothing but a great statesman, in

Demosthenes nothing but a noisy demagogue. Yet his zeal, which so often led him astray, also urged him, for the very purpose of substantiating his views, to search more minutely and critically than his predecessors into certain portions of Greek history, and the result was that Mitford's work held the highest place in the opinion of scholars until the appearance of Thirlwall and Grote. He sat in parliament from 1783 to 1818, and died at Exbury, 8th February 1827.

See the Memoir prefixed to the 7th edition of his *History* (1838) by his brother John Freeman Mitford (1748-1830), who was Lord Chancellor of Ireland (1802-1806), and was raised to the peerage as Lord Redesdale.

Mithra, or MITHRAS, an oriental god whose local worship, extending from Persia, developed into a widespread religion (Mithraism), the great rival in the first centuries after Christ of Christianity.

The god Mithra would seem to have been known to the Indo-Iranians before their separation, for he appears in both Veda and Avesta. In the first his position is important, but not clearly defined; in the second it is clearly defined, but less important; thus in the Veda he is invoked along with Ormuzd, the sovereign of good, but no more than vaguely; while in the Avesta he is a spirit of the second rank or *yazata*, but occupies a definite rôle as the chief of these spirits, and as intermediate between Ahriman, the lord of evil, and Ormuzd, on whose side, in conflict with the former, he always fights. While in India Mithra seems to have been early superseded, in Persia his cult became important. Above all he was a god of light, and by transfer to the moral world a god of truth; but he was, too, a deity of vegetation and of increase, a prosperer of the good and a destroyer of the bad, a champion of armies and of heroes, an enemy of evil spirits, a protector of souls, and a redeemer. With the growth of the Persian empire the worship of Mithra spread throughout Asia Minor, and there was modified—at times Mithra came to be identified with sun-gods—though never essentially altered by contact with various religions. The fall of Persia in no way affected the popularity of the religion, and its spread continued. Most remarkable was its progress in the Roman world. First introduced into Rome in 68 B.C., possibly by some Cilician pirates captured by Pompey, the faith gained a foothold only gradually in Italy. Towards the close of the 2d century after Christ, however, it began to spread rapidly among the military and mercantile classes, and so was borne to the farthest limits of the empire; thus tablets found at Housesteads in the Roman wall, at York, and elsewhere, are proof of the presence of Mithraism in Britain. Later gaining support both on political and on philosophical grounds, it came to number its adherents among every class, and by the middle of the 3d century seemed on the point of triumphing over Christianity as the universal religion. But at the end of the same century, following the northern invasions and the increasing aggression of Christianity, its downfall began, and by the end of the next century may be said to have been completed, though in the 5th century the cult still survived in parts of the Alps. In the East it died more slowly, and found a successor in Manichæism, in which was combined the adoration of Christ and of Zoroaster.

The worship of Mithra was originally conducted in caverns, but in the Roman world was characteristically celebrated in small temples or Mithræums wholly or partially constructed underground, surviving examples of which, as at Rome, Ostia, Capua, and at places outside Italy, are in no sense rare. In these temples was to be found the symbolism of the religion in relief. Notable in this connection is the monument from Oster-

burken in Germany. In the typical relief Mithra is invariably represented in the form of a youth, with conical cap and flying drapery, slaying a bull by plunging a dagger into its side; a scorpion attacks the genitals of the animal, a serpent drinks its blood, a dog springs towards the wound; and frequently, in addition, there are representations of the sun-god, of his messenger the raven, of a fig-tree, of a lion, of a ewer, and of torch-bearers. In some instances this typical or main relief is surrounded by lesser reliefs which need not be here described, but which in the view of Cumont are to be taken as falling into two groups. The symbolism of the various reliefs has been interpreted by Cumont. According to him the first group of lesser reliefs illustrates the legend of the origin of the gods, is, indeed, a representation of Mithraic theology, Mithra appearing in the divine hierarchy as the mediator between suffering humanity and the unknowable and inaccessible god of all being. The second group of lesser reliefs Cumont takes as picturing the legend of Mithra; incidents in the legend, when reconstructed, are the birth of Mithra from a rock and his adoration by shepherds; his clothing himself in fig-leaves; his undertaking to vanquish all beings already in the world; his reluctant slaying, as the servant of an omnipotent deity, of a sacred bull, from which, in spite of the powers of darkness, springs the life of the earth; his conquest of drought by drawing water from a rock; his saving of one man and his cattle from universal deluge; his final banquet with the sun; his ascent to the habitation of the immortals, whence he continues to protect the faithful. From the interpretation of the second group of lesser reliefs the meaning of the main relief above described becomes apparent—it represents one incident in the legend of Mithra, his life-giving sacrifice of the sacred bull; there was also an astrological symbolism, but it was of secondary importance.

In the worship of Mithra a system of secret rites and mysteries played a part, it would seem, of great importance. For the mystic, seven degrees or successive steps were assigned, each marked by a symbolical name—*Corax* (Raven), *Cryphius* (Occult), *Miles* (Soldier), *Leo* (Lion), *Perses* (Persian), *Heliodromus* (Courier of the Sun), *Pater* (Father). Mystics not beyond the third degree were not in full communion, but the fourth degree admitted to full initiation. The various degrees were conferred by the *Patres*—devotees, that is to say, who had been admitted to the seventh degree—the mystic having previously been prepared by lustral purification, by prolonged abstinence, and by severe deprivation. Special ceremonies, such as the marking of the forehead in a kind of baptism, the application of honey to the tongue and hands, a communion of bread, water, and possibly wine, accompanied the several degrees; and other rites more or less barbarous in character, together with some, such as the administration of oaths, the repetition of sacred formulæ, the manipulation of lights in Mithræums, all had their place in the cult. Sacrifices, too, were offered by priests, who, in addition, kept alight an eternal altar-fire, and three times a day addressed prayers to the sun. The cult was supported mainly by voluntary effort. Women had no place in the religion, but among its male worshippers an essentially democratic element would seem to have eliminated distinctions between rich and poor, though in point of fact the devotees of the religion were usually from the humbler classes.

Owing to the almost complete lack of documentary evidence, knowledge of the beliefs of Mithraism, as of much else in the religion, is no more than vague and imperfect. Certain it is,

however, that the faith, personal as it was in character, and applying as it did the processes of the struggles and regeneration of nature to the case of the human soul, had in it much to satisfy real moral needs. Throughout stress is laid on the constant struggle between good and evil. For the defeat of evil moral rectitude is called for. Given that rectitude, however, victory is assured both in this world and in the world to come, for Mithra the unconquered is ever on the side of the faithful. For the worthy soul there is ascent into heaven, where a better life compensates for the sufferings of earth; for the unworthy there is descent into the realms of darkness. But one day the struggle between good and evil is to cease, and Mithra descending is to call all men from their tombs, separating the just from the unjust. The unjust are to be destroyed by fire, but the just are to be rendered immortal in body no less than in soul; then the universe renewed is to enjoy eternal happiness.

Parallels to Christianity in Mithraic legend, in Mithraic ceremony, and in Mithraic belief will have been apparent, and other resemblances, as the sanctification of Sunday and of the 25th of December, the birthday of Mithra, might be cited. But there were also marked differences. Thus Christianity was rigidly monotheistic, while Mithraism was not clearly so, and in a manner combined monotheism with polytheism; Christianity claimed an historical personage as its founder, Mithra a mythical character; Christianity held a place for women, Mithraism excluded them wholly, as has been seen, from its privileges. The points of similarity in the two religions rendered the struggle between them the fiercer, but in the end it was just the differences of the two beliefs which gave to Christianity and not to Mithraism the victory.

The standard authority is Cumont. See his *Textes et monuments figurés relatifs aux mystères de Mithra* (with bibliography, 2 vols. Brussels, 1896-99). His *Les Mystères de Mithra* (Eng. trans. by McCormack, 1903) gives his main conclusions from the *Textes*, and also in the Paris 1913 edition continues the bibliography. Other works are Phythian-Adams, *Mithraism* (1915), and L. Patterson, *Mithraism and Christianity* (1921).

Mithradates (less properly MITHRIDATES; Persian, 'given by Mithras'), the name of several kings of Pontus, Armenia, and Parthia, all of whom have sunk into insignificance, with the exception of Mithradates VI. of Pontus, surnamed Eupator, but more generally known as Mithradates the Great. He succeeded his father, probably about 120 B.C., before the age of thirteen, and soon after subdued the tribes that bordered on the Euxine as far as the Chersonesus Taurica (Crimea). The jealous behaviour of the Romans, and the promptings of his own ambitious spirit, now incited him to invade Cappadocia and Bithynia, but a wholesome fear of the power of the great republic induced him to restore his conquests. The *First Mithradatic War* was commenced by the king of Bithynia (88 B.C.), who, at the instigation of the Romans, invaded Pontus. The generals of Mithradates repeatedly defeated the Asiatic levies of the Romans, and he himself took possession of Bithynia, Cappadocia, Phrygia, and the Roman possessions in Asia Minor. He also sent three powerful armies to aid the Greeks. He was, however, driven from Pergamus (85 B.C.) by Flavius Fimbria, and reduced to the necessity of making peace with Sulla, relinquishing all his conquests in Asia, giving up 70 war-galleys to the Romans, and paying 2000 talents. The wanton aggressions of Murena, the Roman legate, gave rise to the *Second Mithradatic War* (83-81 B.C.), in which Mithradates was wholly successful. In 74 B.C. he invaded Bithynia, commencing the *Third Mithradatic War*. He obtained

the services of Roman officers of the Marian party, and his arms were at first prosperous; but afterwards the Roman consul Lucullus compelled him to take refuge with Tigranes of Armenia (72 B.C.). Lucullus then conquered Pontus, defeated Tigranes (69 B.C.) at Tigranocerta, and both Tigranes and Mithradates at Artaxata (68 B.C.). Mithradates, however, recovered possession of Pontus. After the war had lingered for some time Pompey completed the work of Lucullus (66 B.C.), defeating Mithradates on the Euphrates, and compelling him to flee to his territories on the Cimmerian Bosphorus. Here his indomitable spirit prompted him to form a new scheme of vengeance, which was, however, frustrated by the rebellion of his son, Pharnaces, who besieged him in Panticapæum. Deeming his cause hopeless, Mithradates put an end to his own life (63 B.C.). Mithradates was a specimen of the true eastern despot, possessing great ability and extraordinary energy and perseverance. He had received a Greek education at Sinope, is said to have spoken the twenty-two languages and dialects of his subject-peoples, and made a great collection of pictures, statues, and engraved gems.

Mitrailleuse. See MACHINE GUN.

Mitral Valve. See HEART.

Mitre (Lat. *mitra*, also *infula*), the head-dress worn by bishops in solemn church services. The name, as probably the ornament itself, is borrowed from the orientals, although, in its present form, it is not in use in the Greek Church, or in any other of the churches of the various eastern rites. The western mitre is a tall, tongue-shaped cap, terminating in a twofold point, which is supposed to symbolise the

Mitre.

'cloven tongues,' in the form of which the Holy Ghost was imparted to the apostles, and is furnished with two flaps, which fall behind over the shoulders. Opinion is much divided as to the date at which the mitre first came into use.

Eusebius, Gregory of Nazianzus, Epiphanius, and others speak of an ornamented head-dress, worn in the church; but the cleft mitre does not seem to have been known till the 12th century. The material used in the manufacture of the mitre is very various, often consisting of most costly stuffs, studded with gold and precious stones. The mitre of the pope is of quite a different form, and is called by the name *Tiara* (q.v.). Although the mitre properly belongs to bishops only, its use has been permitted by special privilege to certain abbots, to provosts of some distinguished cathedral chapters, and to a few other dignitaries.

In the English Church, since the Reformation, the mitre was no longer a part of the episcopal costume till 1885, when it was resumed by the Bishop of Lincoln; but it is placed over the shield of an archbishop or bishop, instead of a crest. The Bishops of Durham surround their mitre with a ducal coronet, in consequence of their having been till 1836 Counts Palatine of Durham.

Mitscherlich, EILHARD, chemist, was born at Neuende, near Jever in Oldenburg, Germany, on 7th January 1794, and died at Schöneberg near Berlin on 28th August 1863. At the university of Heidelberg (1811-13) he devoted himself to philology, especially to Persian. At this time of his life his ambition was to go to Persia, and for this end he visited Paris and began to study medicine in Göttingen after 1814. But whilst studying medicine, his deepest interest was arrested by the

sciences of geology and mineralogy, chemistry and physics. Work in the Berlin laboratory in 1819 led him to discover the law of Isomorphism (q.v.). Berzelius invited the young chemist to Stockholm (1820), from which city he returned (1822) to fill the chair of Chemistry at Berlin. One of his earliest discoveries after his appointment was that of the double crystalline form of sulphur, one of the first observed cases of Dimorphism (q.v.). His investigations regarding the production of artificial minerals, and his memoirs on benzene and the formation of ether, must also be noted. His principal work is *Lehrbuch der Chemie* (2 vols. 1829-35; 4th ed. 1840-48; 5th begun in 1855, but not completed). See Memoir by Rose (Berlin, 1864).

Mittweida, a town of Saxony, 11 miles NE. of Chemnitz, manufactures linen, woollen, and cotton goods; pop. 17,000.

Mitylene. See LESBOS.

Mivart, ST GEORGE (1827-1900), educated for the bar, devoted himself to biology, and was professor in the Roman Catholic College at Kensington in 1874-84, and in the University of Louvain in 1890-93. A zealous opponent of Darwinian Natural Selection (though an Evolutionist), he was yet too heterodox or 'modern' for the church authorities, and ten weeks before his death was excommunicated by Cardinal Vaughan for articles in the *Contemporary* and *Nineteenth Century*.

Mnemonics (Gk. *mnēmōn*, 'mindful'), the art of assisting the memory by artificial devices. Thus the value of π , 3.1415926536, can be fixed by help of such a sentence as *But I must a while endeavour to reckon right the ratios*. Each word supplies, by the number of its letters, a figure of the ratio to be remembered. Some rhythmical mnemotechnic contrivances have been used for ages: one, for example, which, notwithstanding the enormous multiplication of printed calendars, still survives is, 'Thirty days hath September,' &c. The Latin student is thankful for the mnemonic rhyme for the dates of the ides and nones; and for centuries no text-book on logic has omitted the five hexameter lines ('Barbara, Celarent,' &c.) which compress the doctrine of the syllogism into a marvellous minimum of space.

Plato and Aristotle refer to a system of 'topical mnemonics' attributed to Simonides the poet, who died 469 B.C. The speaker having selected, for example, a house with which he is so familiar as to remember well the position, not only of each room and passage, but of all the prominent objects in every room, associates as vividly as possible the introduction of his discourse with the entrance-hall, and systematically assigns thought after thought to the chief points there visible. The first main division of his subject may then be identified with the dining-room; and every piece of furniture, every picture, &c., utilised for recalling the succession of arguments with their illustrations and results; and thus for the rest of his discourse. Another form of topical mnemotechny was based on imagining the four walls of each room, and its floor, to be each divided into nine places, and a distinct object—such as a particular bust, picture, or tree, &c.—to be inseparably associated with each place. Then the mnemotechnist who has a succession of things to be remembered assigns them to a particular room and compels himself to detect some association, no matter how incongruous, between each of them and one of the 'hieroglyphs.'

Many minor systems for learning dates and detached numbers have been based on that of Gregor von Feinaigle, a German who lectured in London, 1811. His scheme was

1	2	3	4	5	6	7	8	9	0
t	n	m	r	l	d	k	b	p	s

each letter was more or less suggestive of the figure which it represents: moreover, *p* may be supplanted by *f*, *k* by *c* or *g*, and *b* by *v* or *w*, &c. Thus, as an example, the Anglian kingdom from the Humber to the Firth of Forth was founded in 547, and by Feinaigle's scheme that date becomes *lrk*. By inserting vowels we form the mnemonic words *lark, lurk, large, lyric, Alarie*, &c., any one of which the historical student may choose to suit his notions of King Ida the Flamebearer. Another might prefer *la race, la rage*, &c., or Lat. *lorica*. The similar system (1730) of Dr Richard Grey (1694-1771) is less elastic than Feinaigle's. Dr Pick improved Feinaigle's method by introducing a principle not unlike that which we have noted in describing the topical systems. A list of detached words can be recalled in order by inserting between each pair a connective word which links them or forms a bridge. Other mnemotechnists have been Schenkel, 1547; Aimé Paris, 1833; Karl Otto, 1840; Gouraud, 1845; Copner, 1893; Loissette, 1896. Grey's system was really a modification of Winckelmann's, which attracted the notice of Leibniz and gave him the suggestion of a universal alphabet.

Mnemo synē, in Greek Mythology, the daughter of Uranus, and mother of the nine muses by Zeus. The principal seat of her worship was at Eleutherae, in Boeotia.

Moa, a name believed to have been used by the Maoris to designate various large flightless birds (Dinornithidae) of New Zealand, some of which persisted until comparatively recent times. They

were of heavy build, without known wings, and some attained a height of 10 feet. They are known from bones, foot-prints, feathers and eggs, pebbles used in the stomach, and even pieces of skin, muscle, and ligament. Various genera are distinguished, but with considerable uncertainty, Dinornis, Pachyornis, Mesopteryx, Anomalopteryx, and Emeus. The smallest known, *Anomalopteryx parva*, was about the size of a turkey. The figure shows the still surviving Apteryx or Kiwi beside the extinct Moa. See Parker, *Trans. Zoological Soc.*, xiii. (1895).

Restoration of the Moa.

Moabites, a pastoral people, who inhabited the bleak and mountainous country east of the lower part of the Jordan and of the Dead Sea, divided into two portions by the deep bed of the Arnon. Their capitals were Ar-Moab and Kir-Moab (Kerak), both south of the Arnon; and Kerak was the capital in the days of the later Arabs and Seljuks. But their kings often resided in their native places, as Mesha in Dibon, where was discovered in 1868 his inscription, the most important historical record of ancient Palestine. Among other sites of Moab are Medeba, where a very interesting mosaic map of Palestine of about

the 5th century A.D. was found, and Machærus, a fortress of the Herodians, where John the Baptist was imprisoned by Herod Antipas and executed. The soil of Moab is extremely fertile, and many wine-presses have been found, especially in the Jordan Valley. The land, formerly wealthy, populous, and, to judge from Mesha's inscription, far from uncultured, was exposed on the east to the bedouins of the Syrian desert and to both the traders and raiders that followed the route later taken by pilgrims between Syria and Arabia. 'In Moab,' to quote the words of Sir George Adam Smith, 'you never feel out of touch with Arabia, but Western Palestine belongs to the Levant.'

The history of Moab is bound up with that of the neighbouring states, and all were intimately related ethnologically. The Moabites were compelled to become tributary to David (c. 1000 B.C.), and later to Omri (c. 880 B.C.). Mesha records his successful revolt against Israel (c. 850 B.C.), but Jeroboam II. probably again subjected them. They were involved in the Assyrian wars with Palestine, but appear to have suffered slightly. During the weakness and decay of the great empires and the rise of Persia there were widespread movements among the desert-peoples; and at this turning-point of ancient history, when Israel underwent reconstruction (6th century B.C.), the old Moab gradually disappeared, and gave way to the Nabatæans (q.v.) and other tribes. This difference between the destinies of Moab and Israel is the more noteworthy because the language and script and the religious and other institutions of both peoples were very similar. And to these we may add Phœnicia (q.v.). The national god of Moab was Chemosh, even as Yahweh was Israel's: see the important passage, *Judg.* xi. 24. But the deity Ashtar-Chemosh, venerated by Mesha, probably represents a fusion of female and male deities for which there is no exact parallel in Israel. Again, the 700 rude stone monuments found by Conder, though familiar elsewhere, are so rare on Israelite soil as to suggest that Israelite iconoclasm is responsible for their rarity. The 'ban' when Mesha 'devoted' the Israelites of Nebo was familiar in Israel (*Dent.* ii. 34); but the licentious rites of Baal Peor, and the human sacrifice, when Mesha offered his son as a burnt-offering (2 Kings, iii.), though not unknown in Israel, were repeatedly denounced by the prophets; and, although the Moabites doubtless had their own prophets, we hear of no ethical-spiritual seers like those that distinguish the history of Israel.

See the accounts by Tristram (1873), Conder (1883), G. A. Smith (*Hist. Geog. of Holy Land*), by Brünnow and Domaszewski (German, 1904-5) and Musil (Ger. 1907-8), Jaussen (modern customs, French, 1908), and S. Erskine (*Vanished Cities of Arabia*, 1924). For Mesha's inscription, see G. A. Cooke (*North-Sem. Inscr.*, 1903), W. H. Bennett (1911), and Driver (*Ency. Bibl.*, col. 3040; also his commentary on Samuel).

Moawiya. See KHALIF.

Robberly, capital of Randolph county, Missouri, 148 miles by rail WNW. of St Louis, is an important railway junction, and the dépôt of a rich coal country. It has large railway-shops. Pop. 13,000.

Mobile, the principal city and seaport of Alabama, is situated on the west side of Mobile River and at the head of Mobile Bay, which opens into the Gulf of Mexico, and is defended by Fort Morgan. It is 141 miles by rail ENE. of New Orleans, and is built with broad shaded streets on a sandy plain, rising gradually from the river. It has a fine custom-house and post-office, a city hall and market-house, a Roman Catholic cathedral and many other churches, several asylums and

hospitals, a medical college, a Jesuit college, and a convent and school. Mobile contains a floating dry-dock and several shipyards, foundries, cotton and cottonseed-oil mills, canneries, numerous cigar-factories, &c. Before the civil war the chief business was the export of cotton, and it still ranks as the third cotton market in the United States, while the export of timber has grown very large. Mobile was settled by the French in 1702, and was a Spanish town until 1813, and its population still shows traces of this Latin origin. In 1879 the city limits were curtailed somewhat. Pop. (1870) 32,034; (1890) 31,822; (1910) 51,521; (1920) 60,777.

Mobilier, CRÉDIT. See CRÉDIT MOBILIER.

Mobilisation, a word for the art of making an army ready for taking the field. The process consists in bringing the various units to war strength by calling in reserve men, in organising the staff of brigades, divisions, and army corps, constituting the commissariat, medical, and transport services, and in accumulating provisions and munitions. As the work of mobilising an army causes great and inevitable expense, it is only resorted to when hostilities appear imminent.

Mocaya. See ACROCOMIA.

Moccasin, the shoe of the North American Indian, made all of soft hide, and often ornamented.

—The Moccasin Snake (*Toxicophis piscivorus*) of North America is a brown-coloured poisonous swamp snake; the skin is marked with black bars.

Mocha, a seaport, and once the capital of Yemen in Arabia, is situated on the Red Sea, 130 miles WNW. of Aden. From early in the 16th century until the middle of the 17th Mocha was the port from which the coffee of Yemen was principally exported; hence called Mocha coffee. It now exports hides. Pop. 5000.

Mocha Stones are pieces of agate or of chalcedony, containing dendritic infiltrations, often assuming appearances very like finely ramified *confervæ*, &c. They were first brought to Europe from Mocha. Of the same nature with Mocha stones are *Moss Agates*.

Mocking-bird, or MOCKING-THRUSH (*Mimus*), a genus of birds of the family Turdidae, order Passeres, having a more elongated form than the true thrushes, a longer tail, shorter wings, and the

Mocking-bird (*Mimus polyglottus*).

upper mandible more curved at the tip. Twenty species are known, ranging from Canada to Patagonia, and from the West Indies to the Galapagos Islands. The best-known species, the mocking-bird of the United States (*M. polyglottus*), is about the size of the song-thrush; the upper parts of a dark brownish ash colour, the wings and tail nearly black, the under parts brownish white. The mocking-bird is common in almost all parts of

America, from the south of New England to Brazil; north of the Delaware it is only a summer visitant, but in more southern regions it is found at all seasons. It is one of the most common birds of the West Indies, and its exquisite song fills the groves with melody by night, for which reason it is there very generally known as the nightingale. By day the mocking-bird is generally imitative, excelling all birds in its power of imitation, now taking up the song of one bird, and now of another, and often deceiving the most practised ear by its perfect performance. By night its song is for the most part original. It does not confine itself, however, to musical strains; it seems to take equal pleasure in repeating the harshest cries of the feathered tribes, and in domestication readily adds to its accomplishments the imitation of almost any sound which it is accustomed to hear, passing from one to another with great rapidity, so as to produce an incomparable medley. The mocking-bird readily learns to whistle a tune, even of considerable length, but there is no well-authenticated instance of its imitating the human voice. The barking of a dog, the mewing of a cat, the crowing of a cock, the cackling of a hen, the creaking of a wheel-barrow are all within the compass of its powers. During its performances it spreads its wings, expands its tail, and throws itself about, as if full of enthusiasm and enjoyment. The mocking-bird is vocal at all seasons of the year. It enjoys almost everywhere the protection of man, and often makes its nest in a tree or bush close beside a house. The nest is rudely constructed of dried sticks, withered leaves and grasses, and lined internally with fibrous roots. The eggs are of a short ovoid form, and of a light-green colour spotted with amber. For the first brood from four to six are laid; for the second, four or five; and when there is a third brood, seldom more than three. The first brood is hatched about the middle of April. The male is extremely attentive to his mate, and manifests extraordinary courage in driving away enemies from the nest. Mocking-birds often assemble on such occasions, and birds of prey, far superior to them in size and strength, are compelled to retreat. Snakes are killed by reiterated blows on the head, and cats learn to consider the vicinity of a mocking-bird's nest unsafe. The food of the mocking-bird consists chiefly of berries and insects. The mocking-bird is easily reared by the hand if removed early from the nest, but it is said that it never attains in captivity the same wealth of song as in its free state. Another species of mocking-bird is found in the Rocky Mountains, and species of the same genus are among the finest song-birds of the temperate parts of South America.

Mock Orange, a name applied in England to the so-called *Syringa*, properly *Philadelphus*, and in the United States to *Prunus caroliniana*, a small evergreen resembling the cherry-laurel.

Mòd (Gaelic, from Old Norse *mót*, an assembly; cf. Old English *mót*, modern *moot*, and the verb *meet*), an annual gathering for the encouragement of Gaelic literature and Highland music, similar to the Welsh Eisteddfod.

Mode, a name given to the scales of ancient Greek music. The three oldest were composed of two disjunct tetrachords. There was a semitone between the third and fourth notes (reckoning downwards) of each tetrachord in the Dorian mode, between the second and third in the Phrygian, the first and second in the Lydian. From these are got the Hypo-Dorian, Hypo-Phrygian, Hypo-Lydian, each a fifth lower, and the Hyper-Dorian, Hyper-Phrygian, Hyper-Lydian, a fifth higher. In the additional scales the tetrachords become conjunct,

and the 'diatonic tone' (between the tetrachords of the original mode) appears above the upper tetrachord in the Hypo series, below the lower in the Hyper. Other modes of less importance were added later.

The ecclesiastical modes formulated by St Ambrose and St Gregory do not correspond accurately with the Greek modes of the same names. See HARMONY, PLAIN-SONG. For Major and Minor Modes, see SCALE.

Modelling. See CLAY, POTTERY, SCULPTURE.

Modena (anc. *Mutina*), capital of the former duchy of Modena, stands on a broad plain in Northern Italy, 23 miles by rail NW. of Bologna. Pop. of commune (1921) 83,663. It had extensive ramparts, long since converted into promenades, and has fine streets, many of them arched on both sides. The ancient Via Æmilia divides it into the old and new city. The cathedral of St Geminianus, a Romanesque building, was begun, at the instance of the famous Countess Matilda, in 1099, and has a fine façade; its campanile is one of the great towers of Italy. The ducal (now royal) palace, a picturesque structure of the 17th century, has an infinity of galleries, courts, and marble arches, and contains the Este library, the Este archives, collections of coins, and the gallery of pictures, including works by Guido, the Carracci, Guercino, Correggio, and other great Italian masters. Modena has besides a university (1678). The chief manufactured products are silk, leather, vinegar, and cast metals. There is a very lively trade in agricultural products. Originally an Etruscan town, Modena was conquered successively by the Gauls and the Romans, and destroyed by Constantine the Great, the Goths, and the Longobards. Charlemagne made it the capital of a line of counts. The family of Este (q.v.) became its masters in 1288; and in 1452 the reigning marquis was created duke by the Emperor Frederick III. During the first half of the 19th century its dukes pursued a tyrannous reactive policy against liberalism, and were on more than one occasion expelled their dominions, finally and definitively in 1860. The duchy was then incorporated in the kingdom of Italy, and afterwards divided into the provinces of Modena, Reggio, and Massa-Carrara. Area of province, 1000 sq. m.; pop. 400,000.

Moderator, a president, especially (1) in Presbyterian churches the president of a kirk-session, presbytery, synod, or general assembly (see ASSEMBLY, GENERAL), and (2) an official who conducts certain university examinations (in Oxford Moderations or 'Mods,' the first public examination for B.A.; in Cambridge, the Mathematical Tripos).

Modernism, a name used by Swift of innovation in style or expression. In 1704 he called those modernists who maintained the superiority of modern over ancient literature. Rousseau in 1769 spoke of an atheistical philosopher as a modernist. Ruskin in 1874 contrasted 'infidel modernists' with 'dunce Christians.' Much more recent is the use of the term modernism for a series of attempts so to modify the relation of Christian dogma towards history and science, while retaining religious truth intact, as to leave Christian scholars free to pursue their researches in science and history untrammelled by dogmatic limitations, and to accept unhesitatingly conclusions which the church had heretofore branded as rationalism or worse.

Innovating movements in the Roman Catholic Church under Pius IX. usually took a politico-liberal direction; under Leo XIII. they were largely of the nature of social reform; but under Pius X. they assumed an avowedly theological and critical aspect, especially in Italy and France. The leaders

in this latter movement do not by any means all adhere to the same doctrines or positions; but such men as Murri and Fogazzaro in Italy, Loisy in France, Tyrrell and Von Hügel in England, have enough in common to justify their being grouped under a common name. Their critics charge them with having been influenced by elements hostile to Catholicism derived from Kant, from Schleiermacher, from Herbert Spencer, from Bergson; with having carried Newman's doctrine of development to conclusions at which Newman would have shuddered; and with being but little distinguished from 'liberal' Protestants as unlike one another as Harnack, Eucken, and Sabatier. This the Catholic modernists earnestly deny, affirming that they are devout Catholics in heart, seeking only to remove obstacles and stumbling-blocks in the way of faith by bringing church doctrine into perfect harmony with the results of scientific research and free historical studies. They accept the substance of the Catholic faith, and adhere to its ritual as they find it in the 20th century, to its sacred books, its organisation and discipline, only they claim a right fearlessly to apply conscientious and thorough historical and critical methods to the study of the church's origin and development. The representative modernists secure this freedom by their emphatic distinction between religion and dogma, between historic facts and the doctrines which have been developed out of them and built around them by the Christian consciousness of the church. If the faith is alive its expression must take new forms, must seek more adequate presentation, must develop not merely in clearness but in substance. Religious experience does not depend on evidence and scientific fact, nor in the end does Christian faith or Christian doctrine.

Modernism is at once a philosophy, a theology, a method of interpretation, and a system of criticism. In effect it yields up, as matters of science and historic fact, most of the positions negative criticism holds itself to have proved; but claims to rescue the faith from attack and defeat, and believers from doubt and difficulty, by proving that the faith—the Catholic faith in all essentials—is indefeasible, as established on the eternal foundations of religious need, religious aspiration, religious hope, religious assurance. Modernism was condemned by the Italian bishops in 1905 and 1906; by the Papal decree *Lamentabili* (which, however, does not use the word modernism) in July 1907; and by the encyclical *Pascendi*, which confutes 65 'modernist' propositions, in September 1907. Loisy was visited with the major excommunication in 1908; and Tyrrell, expelled from the society of the Jesuits, died in 1909, while his privileges as a Catholic priest were still withdrawn.

The modernising tendency seeks to retain the traditions, the ceremonies, and the discipline of the old faith as far as is consistent with the educated beliefs and conscience of the time, with the accepted facts of history, the principles of service, and developing realisation of a universe in which man is not the centre, and to which man's history is not the key. It tends to minimise the miraculous, and humbly to admit that the laws of nature are also the laws of God; it substitutes the immanent view of God for a merely transcendental; it sets aside for ever the bitterness of dogmatic controversy, dwells as little as may be on the more barren problems of theology, and, reconciling service with religion, seeks to harmonise order with progress, and the welfare of the individual with that of the race.

The Rev. J. M. Thompson is a notable modernist within the Church of England. In *The Miracles of the New Testament* he frankly disavowed his belief in the miraculous element in the gospels;

but in *Through Facts to Faith* (1913) he argues that belief in Providence remains untouched after the miraculous element is eliminated; the testimony of religious experience, in reply to the scientific conclusion that miracles do not happen, is that miracles do not matter. And he even finds himself able to justify the Christian belief in the divinity and deity of Christ on the basis of a providential order (although quite obviously the evangelists based Christ's divine mission and powers on the miracles they recorded).

Modica, an inland town of Sicily, 45 miles SW. of Syracuse, with trade in fruit, oil, wine, and grain; pop. 60,000.

Modjeska, HELENA, Polish actress, was born in Cracow, 12th October 1844, and began to act in a travelling company in 1861. Four years later she made a great name at Cracow, and from 1868 to 1876 was the first actress of Warsaw. Then she settled, with her second husband, near Los Angeles, California, to try farming; but the enterprise not succeeding, she returned to the stage, and won a complete triumph as Adrienne Lecouvreur at San Francisco in 1877, although she acted in English, of which language she had known nothing seven months before. She was acknowledged one of the best of modern emotional actresses, achieving triumphs in Juliet, Rosalind, Beatrice, and in the *Dame aux Camélias*. Returning to farming and bee-keeping in California, she died in April 1909. See her Autobiography (1910).

Modulation, in Music. When in the course of a melody the keynote is changed, and the original scale altered by the introduction of a new sharp or flat, such change is called modulation. Much of the pleasure of music is derived from a judicious use of modulation. The art of good modulation from one key to another consists in the proper choice of intermediate chords.

Moe, JÖRGEN (1815-82). See ASBJÖRNSEN.

Möen, a Danish island in the Baltic Sea, at the south-east end of Zealand. It is 20 miles in length.

Moeris, LAKE (Greek *Moirios limnē*), a sheet of water in Egypt, called in ancient Egyptian *Piōm* ('sea,' whence Fayūm), now represented by the large sheet of brackish water at the north-west end of the oasis of Fayūm (q.v.), covering nearly 80 sq. miles, called the Birket-el-Karūn, or 'Lake of the Horns,' but originally filling the whole depression, about 50 miles SW. of Cairo; extreme length from north-east to south-west, 35 miles.

Moero, or MWERU, LAKE, lies SW. of Tanganyika in Central Africa, on 9° S. lat. and 29° E. long., and is traversed by the Luapula (see CONGO). This lake was discovered by Livingstone in 1867. Its shores yield salt.

Moesia, an ancient Roman province, divided by the river Cibus (Zibritza) into two parts, the eastern corresponding to part of Bulgaria, and the western (Moesia Superior) to part of Serbia. Its original inhabitants were mostly of Thracian race. In 75 B.C. the Romans first came into conflict with the Gaulish or Celtic invaders of the land, who had settled in Upper Moesia two hundred years previously; but they did not conquer Upper Moesia until 29 B.C. and Lower until 15 B.C. To protect these provinces from the Dacians and Sarmatians beyond the river a wall was built and fortified posts erected along the Danube. The Emperor Valens permitted the Visigoths to settle in Moesia in 375 A.D. From the 5th to the 7th century Moesia was colonised by the races who still occupy it.

Mæso-Goths, the name given to the Goths (q.v.) who in the 3d century and in the 5th settled

in Lower Mœsia. It was for them that Ulfilas (q.v.) translated the Scriptures.

Moffat, a pleasant watering-place and police burgh in Upper Annandale, Dumfriesshire, 51 miles SSW. of Edinburgh by road. It lies 370 feet above sea-level, engirt by round grassy hills (the loftiest, Hartfell, 2651 feet), and in the midst of delightful scenery, chief features of which are 'dark Loch Skene,' the Grey Mare's Tail, and the Devil's Beef-tub. Its mineral springs have been celebrated since 1653. Pop. 3000.

Moffat, ROBERT, missionary, was born at Ormiston, East Lothian, 21st December 1795. While following the occupation of a gardener at High Leigh, Cheshire, in 1815, he offered himself for the mission-field. His services were accepted by the London Missionary Society, and he sailed for South Africa in 1816. He began his labours (January 1818) in Great Namaqualand at the kraal of Afrikaner, a chief who from being a terror to the neighbouring districts of the colony had embraced Christianity, and now showed a desire for its promotion. On 27th December 1819 Moffat married Mary Smith (1795-1870), daughter of his former employer at Dukinfield near Manchester, who proved a worthy helpmeet. He made several journeys and laboured at various stations before he settled at Kuruman (1826-70) in Bechuanaland. He printed in Sechwana the New Testament (1840), the Old Testament (1857), and several religious works. In England (1838-43) he had an enthusiastic reception, and published his graphic *Labours and Scenes in South Africa* (1842). In 1843 he returned, reinforced by other missionaries, remaining till 1870. He died at Leigh, Kent, 9th August 1883. It may be said that Moffat's influence drew Livingstone to Africa; it was to Kuruman Livingstone went first, and he married Mary Moffat. See *Lives of Robert and Mary Moffat*, by J. S. Moffat (1885).

Mofussil (from an Arabic word meaning 'separate'), a term commonly used by Anglo-Indians for the rural part of a district as opposed to the administrative headquarters. Thus in Bengal the Mofussil means practically the whole province beyond the city of Calcutta.

Mogador, or SUEÏRA, a seaport 130 miles WSW. of the city of Marrakesh. Pop. about 20,000, of whom 700 are Europeans. It stands on a rocky promontory opposite a small island, the channel between forming the somewhat indifferent harbour. It was laid out in 1760 by Cornut, a French engineer. On its landward side the place is surrounded by drifting sandhills, but the climate is salubrious, dry, and temperate.

Mogileff. See MOHILEFF.

Mogok, the centre of a ruby-mining district of Burma, 90 miles NNE. of Mandalay.

Moguer, a town and small port of Spain, on the Río Tinto, near its mouth, and 8 miles E. of Huelva, with some trade; pop. 8000.

Mogul, also spelt *Moghul* and *Mughal*, is really but another form of *Mongol*. The term 'great Mogul' is the popular designation of the emperor of Delhi in India. The first Great Mogul was Baber (q.v.), a descendant of Timur the Tatar or Tamerlane (q.v.); he founded the empire in 1526. The dynasty lost its power and territories to the English in 1765. The last emperor, having joined the rebels in 1857, died a prisoner in Rangoon (1862). See Irvine, *The Later Mughals* (1922).

Moguntiacum, the Latin name of Mainz (q.v.).

Mohács, a town of Hungary, on the western arm of the Danube, 37 miles by rail ESE. of Fünfkirchen; pop. 16,000. Here, on 29th August

1526, Louis II. of Hungary, with 25,000 Hungarians, met the Sultan Soliman at the head of 200,000 Turks. The battle resulted in the disastrous defeat of the Hungarians, who lost their king, seven bishops, many nobles and dignitaries, and upwards of 22,000 men. In a second battle fought here on 12th August 1687 the Turks in their turn were defeated by an Austro-Hungarian army under Charles of Lorraine.

Mohair, the wool of the Angora Goat (q.v.). Few animals have so beautiful a covering as the fine, soft, silky, long, and always pure white wool of this goat. See WOOL.

Mohammed (*Muhammad*, and less correctly *Mahomet*; Arab., 'Praised'), the founder of Islam. He was born about the year 570 A.D. at Mecca, the son of Abdallah, of the family of the Hashim, and of Amina, of the family of Zuhra, both of the powerful tribe of Koreish (Quraish). His father died probably shortly after Mohammed's birth, and the boy spent his infancy and part of his childhood with Halima among the Beni Sa'd. His grandfather, 'Abd-al-Muttalib, the foremost chief of Mecca and keeper of the holy place, adopted him on the death of Amina, which occurred when Mohammed was six years old. Two years later 'Abd-al-Muttalib also died, and Mohammed came under the guardianship of his uncle, Abu Talib, who, finding himself too poor to provide for the pilgrims, handed over this expensive duty, along with the charge of the well Zemzem, to his younger brother Al-Abbās, from whom in days to come were descended the powerful family of the Abbasids. Abu-Talib proved a kind friend and guardian to his nephew throughout his life. Thoughtful beyond his years and endowed with a refined mind and delicate tastes Mohammed kept himself singularly pure in a society where purity meant little or nothing, and for this he became known as Al-Amin, 'The Faithful.' During his youth he tended the flocks of Mecca on the hills surrounding the city, and in after years he is reported to have said, 'Verily there hath been no prophet raised up who performed not the work of a Shepherd.' At twenty-five he hired himself to Khadija, a wealthy widow, also descended from the Koreish, for four camels, to go with one of her caravans to Syria. The undertaking was a complete success commercially, and led, through the greater chances of meeting, to what may well be considered the event which more than any other led to Mohammed's happiness—his marriage with Khadija. This marriage with Khadija (fifteen years his senior) gave him that ease of circumstances and freedom from the cares of daily life which he needed. Within the next ten years Khadija bore to Mohammed two sons and four daughters. The first-born was named Al-Kāsim; and after him, according to Arabian custom, Mohammed received the name Abu'l-Kāsim, 'Father of Al-Kāsim'; next were born his four daughters, Zeinab, Rokeiya, Fātima, and Um Kuthūm; and lastly, his second son, Abd-Mānaf. Both his sons died young.

No description of Mohammed at this period has been attempted by traditionists. But from many accounts given of his person in later life an outline of his appearance in early manhood may be attempted. Slightly above middle height, his figure though lean was handsome. Broad-shouldered and strongly built, he was fair skinned for an Arab; his neck was long and finely moulded, his hair jet-black and slightly curly fell to his shoulders, while a long beard added to the dignity of his appearance. A black mole between his shoulders became known afterwards among the faithful as 'the seal of prophecy.' His expression

was pensive and thoughtful, and the face was full of intelligence, although something sensuous might also be discerned. He leaned slightly forward as he walked, and his step was sharp and decided, though he moved his whole body somewhat violently, which gave him the look of one descending a declivity.

Throughout Arabia, from about the year 600, Christianity and Judaism had played prominent parts in the peninsula. Also at this time there had arisen several men from the Hejaz, who preached the Unity of God (the ancient religion of Abraham) in opposition to the futility of the ancient pagan creed with its star worship, pilgrimages, temples, and fetishes. In fact, these Hanifs may be considered the forerunners of Mohammed, for by their zeal they aroused many from their pagan beliefs to join either Christianity or Judaism.

In his fortieth year, while passing the time, as he was so fond of doing, at Mount Hira, in the neighbourhood of Mecca, he received his first communication from God. Gabriel appeared to him with a message from his Lord, 'Cry (recite) in the name of thy Lord who created all things.' Greatly terrified at this revelation he returned to Khadija, who comforted him. The visions after this were withheld for some years, and on their return he only communicated them to Khadija, his daughters, his cousin and adopted son Ali, his former slave and adopted son Zaid, and his friend the prudent, wise, and honest Abū Bekr. His other relatives rejected his teaching with scorn. Abu Lāhab, his uncle, called him a fool; and Abu Tālib, his adopted father, though he never ceased for the honour of his family to protect him, yet never professed any belief in Mohammed's words. In the fourth year of his mission, however, he had made forty proselytes, chiefly slaves and people from the lower ranks, and now first some verses were revealed to him, commanding him to come forward publicly as a preacher, and to defy the scorn of the unbelievers. He now inveighed against the primeval superstition of the Meccans, and exhorted them to a pious and moral life, and to the belief in an all-mighty, all-wise, everlasting, indivisible, all-just, but merciful God, who had chosen him as he had chosen the prophets of the Bible before him, so to teach mankind that they should escape the punishments of hell, and inherit everlasting life. God's mercy was principally to be obtained by prayer, fasting, and almsgiving. The belief in the sacredness of the Kāaba and the ceremonies of the pilgrimage was too firmly rooted in his and the people's minds not to be received into the new creed; but certain barbarous habits of the Bedouins, such as the killing of their new-born daughters, were unsparingly condemned by Mohammed. The prohibition of certain kinds of food also belongs to this first period, when he as yet entirely stood under the influence of Judaism; the prohibition of gambling, usury, and wine coming after the Hegira. Whether he did or did not understand the art of writing and reading at the commencement of his career is not quite clear; certain it is that he pretended not to know it, and employed the services of amanuenses for his Koranic dicta, which at first consisted merely of brief, rhymed sentences in the manner of the ancient Arabic soothsayers. Zaid, his adopted son, who was later to gather these fragments into a complete whole (see KORAN), was his chief secretary. The Meccans did not object to his doings; they considered him a common poet or soothsayer, who, moreover, was not in his right senses, or was simply a liar. Gradually, however, as the number of his converts increased they began to pay more and more attention to his proceedings; and finally, fearing mostly for the sacredness of Mecca, which the new doctrine

might abolish, they rose in fierce opposition against the new prophet and his adherents, who dared 'to call their ancient gods idols, and their ancestors fools.' The Koreish now demanded that Abu Tālib should silence or surrender his nephew. Abu Tālib refused. Many of the converted slaves and freedmen had to undergo terrible punishments; and others suffered so much at the hands of their own relatives that they were fain to revoke their creed. A hundred believers, on the prophet's own advice, emigrated to Abyssinia. Mohammed himself, although protected by the strong arm of Abu Tālib, was yet at that time so low-spirited and fearful that, before an assembly of the Koreish, he raised three of the idols to mediatorial beings between God and man—a dictum, however, which he next day revoked as an inspiration of Satan, thereby increasing the hatred of his adversaries. All the Hāshimi family were now excommunicated, and all except Abu Lāhab retired to Abu Tālib's ravine in the mountains east of Mecca. After two years they were restored when on the brink of starvation.

A great grief befell Mohammed at this time—his faithful wife Khadija died, and, shortly afterwards, his uncle Abu Tālib; and, to add to his misery, the vicissitudes of his career had reduced him by this time to poverty. An emigration to Taif proved a failure; it was with great difficulty that he escaped with his life. Shortly after his return from Taif he married Sauda, and he afterwards so increased the number of his wives that at his death he still left nine, of whom Ayesha, the daughter of Abū Bekr, and Hafsa, the daughter of Omar, are best known. In the midst of his vain endeavours to find a hearing in his own city he succeeded, during a pilgrimage, in converting several men from Medina, whose inhabitants had long been accustomed to hear from the numerous Jews there the words Revelation, Prophecy, God's Word, Messiah. The seed sown in the minds of these men bore a fruitful harvest. While he waited for the next pilgrimage he had in vision his night journey to heaven, the relation of which caused even his staunchest adherents to smile at his hallucination. The next pilgrimage brought twelve, and the third more than seventy adherents to the new faith from Medina, and with these he entered into a close alliance. Mohammed now conceived the plan to seek refuge in the friendly city of Medina, and about June 622 A.D. he fled thither. About one hundred families of his faithful flock had preceded him some time before, accompanied by Abū Bekr, and reached, not without danger, the town, called previously Yathrib, but thence Medinat Alnabi ('City of the Prophet'), or Medina ('City'), by way of eminence; and from this flight dates the Mohammedan Era, the Hegira (q.v.).

Now everything was changed to the advantage of the prophet and his religion; and if formerly the incidents of his life are shrouded in comparative obscurity, they are from this date known often to their most insignificant details. Formerly a despised 'madman or impostor,' he now assumed at once the position of highest judge, lawgiver, and ruler of the city and two most powerful Arabic tribes. His first care was directed towards the consolidation of the new worship, and the inner arrangements in the congregation of his flock; his next chief endeavour was to proselytise the numerous Jews who inhabited the city, to whom he made many important concessions also in the outer observances of Islam, but he was sorely disappointed in his hopes to convert them. They ridiculed his pretension to be the Messiah, and so enraged him by their constant taunts that he soon abrogated his concessions and became their bitterest adversary up to the hour of his death. The most important act in the first year of the Hegira was his permission

to go to war with the enemies of Islam in the name of God—a kind of manifesto chiefly directed against the Meccans. Not being able at first to fight his enemies in open field, he endeavoured to weaken their power by attacking the caravans of the Koreish on their way to Syria. Being successful enough to disturb their trade and to conclude alliances with the adjoining Bedouin tribes, he at last dared to break even the peace of the sacred month of Radjab, and with this the signal to open warfare was given. A battle, the first, between 300 Moslems and about 600 Meccans was fought at Badr, in the second year of the Hegira, December 623; the former gained the victory and made many prisoners. This battle is one of the outstanding events in Moslem history, and the moral effect never left Mohammed. A great number of adventurers now flocked to him, and he successfully continued his expeditions against the Koreish and the Jewish tribes, chiefly the Beni Keinukâ and the Beni Kureidhah. In January 625 the Meccans defeated him at Uhud, where he was dangerously wounded. The siege of Medina by the Meccans in 627 was frustrated by Mohammed's ditch and earthworks. In 628 he proclaimed a public pilgrimage to Mecca. Although the Meccans did not allow this to be carried out, he gained the still greater advantage that they concluded a term of peace with him at Hudaibiyeh for ten years. He was now allowed to send his missionaries all over Arabia, and even beyond the frontiers, without any hindrance; and in the following year he had the satisfaction of celebrating the pilgrimage with 2000 followers for three days undisturbed at Mecca. Shortly afterwards, during his expeditions against the Jews of Chaibar and Fadak, Mohammed very nearly lost his life: a Jewess, Zainab by name, a relative of whom had fallen in the fight against him, placed a poisoned piece of roast meat before him, and although he merely tasted it he yet up to his death suffered from the effects of the poison. His missionaries at this time began to carry his doctrines abroad. He wrote letters demanding the conversion of Chosroes II., of Heraclius, of the king of Abyssinia, the Viceroy of Egypt, and the chiefs of several Arabic provinces. Some received the new gospel, but Chosroes II., the king of Persia, and Amru the Ghassanide rejected his proposals with scorn, and the latter had the messenger executed in Moab. This was the cause of the first war between the Christians and the Moslems, in which the latter were beaten with great loss by Amru. Some Meccans having taken part in a war between a tribe in their alliance and another in Mohammed's alliance, he marched at the head of 10,000 men against Mecca before its inhabitants had had time to prepare for the siege. It surrendered, and Mohammed was publicly recognised as chief and prophet. With this the victory of the new religion was secured in Arabia. While employed in destroying all traces of idolatry in the captured city Mohammed heard of new armies which several warlike Arabic tribes had concentrated near Taif (630). There again he was victorious, and now his dominion and creed extended farther and farther every day. From all parts flocked the deputations to do homage to him in the name of the various tribes, either as the messenger of God or at least as the Prince of Arabia, and the year 8 of the Hegira was therefore called the year of the Deputations. Once more he made most extensive preparations for a war against the Syrian subjects of Byzantium; but, not being able to bring together a sufficient army, he had to be satisfied with the homage of a few minor princes on his way to the frontiers. Towards the end of the tenth year of the Hegira he undertook his last solemn pilgrimage to Mecca, and there on Mount

Arafat fixed for all time the ceremonies of the pilgrimage (Hajj); and he again solemnly exhorted his believers to righteousness and piety, and chiefly recommended them to protect the weak, the poor, and the women, and to abstain from usury.

Returned from Mecca, he occupied himself again with the carrying out of his expedition against Syria, a necessary aid to religion and patriotism in keeping his people together, but fell dangerously ill very soon after his return. One night while suffering from an attack of fever he went to the cemetery of Medina and prayed and wept upon the tombs, praising the dead, and wishing that he himself might soon be delivered from the storms of this world. For a few more days he went about; at last, too weak further to visit his wives, he chose the house of Ayesha, situated near the mosque, as his abode during his sickness. He continued to take part in the public prayers as long as he could, until at last, feeling that his hour had come, he once more preached to the people recommending Osâma the son of Zaid as the general whom he had chosen for the army, and Abû Bekr as his particular friend. He then asked whether he had wronged any one, and read passages from the Koran preparing the minds of his hearers for his death and exhorting them to peace among themselves. A few days afterwards he asked for writing materials, probably in order to fix his successor as chief of the faithful; but for some reason they were not brought to him. In his last wanderings he spoke only of angels and heaven. He died in the lap of Ayesha about noon of Monday the 12th (11th) of the third month in the year 11 of the Hegira (8th June 632). His death caused an immense excitement and distress among the faithful; and Omar, who himself would not believe in it, tried to persuade the people that he was still alive. But Abû Bekr said to the assembled multitude: 'Whoever among you has served Mohammed let him know that Mohammed is dead; but he who has served the God of Mohammed let him continue in His service, for He is still alive and never dies.' While his corpse was yet unburied the quarrels about his successor, whom he had not definitely been able to appoint, commenced; but finally Abû Bekr received the homage of the principal Moslems at Medina. Mohammed was then buried in the night between the 9th and 10th of June, after long discussions, in the house of Ayesha, where he had died. It afterwards became part of the adjoining mosque.

A man of Mohammed's extraordinary powers and gifts is not to be judged by a modern commonplace standard; the manners and morals of his own time and country must also be taken into consideration. He was at times deceitful, cunning, revengeful, cowardly, addicted to sensuality, and even a murderer. Yet not only his public station as prophet, preacher, and prince, but also his private character, his amiability, his faithfulness towards friends, his tenderness towards his family, and the frequent readiness to forgive an enemy must be taken into consideration, besides the extreme simplicity of his domestic life; he lived when already in full power in a miserable hut, mended his own clothes, and freed all his slaves. His melancholic temperament, his nervousness, his poetic nature, his extreme sensitiveness which sometimes developed by introspection into hysteria, must not be forgotten. Altogether his mind contained the strangest mixture of right and wrong, of truth and error. Although his self-chosen mission was the abolition of superstition, he yet believed in jinn, omens, charms, and dreams. Take him all in all, the history of humanity has seen few more earnest, noble, and sincere prophets, men

irresistibly impelled by an inner power to admonish and to teach, and to utter austere and sublime truths the full purport of which is often unknown to themselves.

See the *Lives* in German by Weil (1843), Sprenger (1861-65), Nöldeke (1863), Krehl (vol. i. 1884); in French by Delaporte (1874); Sir W. Muir, *Life of Muhomet* (4 vols. 1858-61; ed. Weir, 1912), and *Mahomet and Islam* (1887); Syed Ameer Ali's *Life of him* (1890); P. de L. Johnstone, *Muhammad and his Power* (1901); and Margoliouth, *Mohammed and the Rise of Islam* (1905).

MOHAMMEDANISM, the religion founded by Mohammed, or, according to him, the only orthodox creed existing from the beginning of the world, and preached by all the prophets ever since Adam. It is also called *Islām*, 'Resignation,' entire Submission to the will and precepts of God. In its exclusively dogmatical or theoretical part it is *Imān*, 'Faith'; in its practical, *Dīn*, 'Religion.' The fundamental principles of the former are contained in the two articles of belief: 'There is no God but God; and Mohammed is God's Apostle.' The Mohammedan doctrine of God's nature and attributes coincides with the Christian, in so far as He is by both declared to be the Creator of all things in heaven and earth; who rules and preserves all things, without beginning, omnipotent, omniscient, omnipresent, and full of mercy. But, according to the Mohammedan belief, He has no offspring: 'He begetteth not, nor is He begotten.' Nor is Jesus called anything but a prophet and apostle, although His birth is said to have been due to a miraculous divine operation; and as the Koran superseded the Gospel, so Mohammed superseded Christ. The crucifixion is said to have been carried out upon another person, Christ having been taken up unto God before the decree was put into execution. Christ will come again upon the earth to establish everywhere the Moslem religion, and to be a sign of the coming of the day of judgment. Next to the belief in God, that in angels forms a prominent dogma. Created of fire, and endowed with a kind of incorporeal body, of no sex, they stand between God and man, adoring or waiting upon God, or interceding for and guarding man. The four chief angels are Gabriel, 'The Holy Spirit' or 'Angel of Revelations'; Michael, the special protector and guardian of the Jews; Raphael (Azraël, Azraïl), the 'Angel of Death'; and Uriel (Israfil), whose office it will be to sound the trumpet at the Resurrection. Islam borrowed its ideas of the unseen world from the Persians or from the Jews, who had borrowed them from the Persians (see ANGEL). To each human being are appointed two guardian angels. Besides angels, there are good and evil genii, the chief of the latter, who are generally called Ifrit, being Iblīs ('Despair'), once called Azazil, who, refusing to pay homage to Adam, was rejected by God. These jinn are of a grosser fabric than angels, and subject to death. They are, in almost every respect, like the Shēdim in the Talmud and Midrash. A further belief is in certain God-given Scriptures, revealed successively to the different prophets. Four only of the original one hundred and four sacred books—the Pentateuch, the Psalms, the Gospel, and the Koran—are said to have survived; the three former, however, in a mutilated and falsified condition. The number of prophets, sent at various times, is stated variously at between two and three hundred thousand, among whom 313 were apostles, and six were specially commissioned to proclaim new laws and dispensations, which abrogated the preceding ones. These were Adam, Noah, Abraham, Moses, Jesus, and Mohammed—the last the greatest of them all, and the founder of the final dispensation.

The belief in the resurrection and the final judgment is the next article of faith. The dead are

received in their graves by an angel announcing the coming of the two examiners, Munkir and Nakir, who put questions to the corpse respecting his belief in God and Mohammed, and who, in accordance with the answers, either torture or comfort him. Concerning the condition of the soul between death and the resurrection Islam has no authoritative teaching. The soul is supposed, according to its rank, either to enter immediately into paradise (as do the prophets), or to partake, in the shape of a green bird, of the delights of the abode of bliss (as the martyrs); while, in the case of common believers, it stays near the grave, or is with Adam in the lowest heaven, or remains either in the well of Zem-Zem or in the trumpet of the resurrection. The souls of the infidels dwell in a certain well in the province of Hadramaut, or, being first offered to heaven, then offered to earth, and rejected by both, are subject to unspeakable tortures until the day of resurrection. Concerning the latter, great discrepancy reigns among the Mohammedan theologians. Mohammed himself seems to have held that both soul and body will be raised; and the 'bone Luz' of the Jewish Haggadah was by him transformed into the bone Al Ajb ('the rump-bone'), which will remain uncorrupted till the last day, and from which the whole body will spring anew, after a forty days' rain. Among the signs by which the approach of the last day may be known—nearly all taken from the legendary part of the Talmud and Midrash—are the decay of faith among men, the advancing of the meanest persons to highest dignities, wars, seditions, and tumults, and consequent dire distress. The sun will rise in the west, the Beast will appear, Constantinople will be taken by the descendants of Isaac, the Mahdi (q.v.) will come, the Dejjāl or arch-impostor also will come and be killed by Jesus at Lud. There will further take place a war with the Jews, the coming of Gog and Magog (Yāyūj and Mājūj's), a great smoke, an eclipse, the Mohammedans will return to idolatry, the Kāaba will be destroyed by the Ethiopians, beasts and inanimate things will speak, and finally, a wind will sweep away the souls of those who have faith. The time of the resurrection Mohammed himself could not learn from Gabriel: it is a mystery. Three blasts will announce it: that of consternation, of such terrible powers that mothers shall neglect the babes on their breasts, and that heaven and earth will melt: that of examination, which will annihilate all things and beings, save paradise and hell, and their inhabitants; and forty years later, that of resurrection, when all men, Mohammed first, shall have their souls breathed into their restored bodies, and will sleep in their sepulchres until the final doom has been passed upon them. The day of judgment, lasting from one to fifty thousand years, will call up angels, genii, men, and animals. The trial over, the righteous will enter paradise to the right hand, and the wicked will pass to the left into hell; both, however, have first to go over the bridge Al Sirāt, laid over the midst of hell, and finer than a hair, and sharper than the edge of a sword, and beset with thorns on either side. The righteous will proceed on their path with ease and swiftness, but the wicked will fall down headlong to hell below.

Hell is divided into seven stories or apartments, respectively assigned to Mohammedans, Jews, Christians, Sabians, Magians, idolators, and, lowest of all, the hypocrites, who, outwardly professing a religion, in reality had none. The degrees of pain, chiefly consisting in intense heat and cold, vary; but Mohammedans and all who professed the unity of God will finally be released, while unbelievers and idolators will be condemned to eternal punishment. Paradise is divided from

hell by a partition (Arâf), in which a certain number of half-saints will find place. The blessed, destined for the abodes of eternal delight (Jannat Aden; Heb. Gan Eden), will first drink of the Pond of the Prophet, which is supplied from the rivers of paradise, whiter than milk, and more odoriferous than musk. Arrived at one of the eight gates, they will be met by beautiful youths and angels; and their degree of righteousness (prophets, religious teachers, martyrs, believers) will procure for them the corresponding degree of happiness. Yet, according to the Mohammedan doctrine, it is not a person's good works or merits that gain his admittance, but solely God's mercy. The poor will enter paradise five hundred years before the rich. The majority of the inhabitants of hell are women. The various felicities which await the pious (and of which there are about a hundred degrees), are a wild conglomeration of Jewish, Christian, Magian, and other fancies on the subject, to which the Prophet's own exceedingly sensual imagination has added largely. Feasting in the most gorgeous and delicious variety, the most costly and brilliant garments, odours and music of the most ravishing nature, and above all, the enjoyment of the Hûr Al Oyûn, the black-eyed daughters of paradise, created of pure musk, and free from all the bodily weaknesses of the female sex, are held out as a reward to the commonest inhabitants of paradise, who will always remain in the full vigour of their youth and manhood. For those deserving a higher degree of recompense rewards will be prepared of a purely spiritual kind—i.e. the 'beholding of God's face' by night and by day. A separate abode of happiness will also be reserved for women. The last of the precepts of pure faith taught by Mohammedanism is the full and unconditional submission to God's decree (Islam), and the predestination of good and evil. Not only a man's fortunes, but his deeds, and consequently his future reward or punishment, are irrevocably, and thus unavoidably, pre-ordained (Fate, *kismeh*): a doctrine which is not, however, taken literally by all Moslems, but which has no doubt contributed largely to the success of Islam by inspiring its champions with the greatest contempt for the dangers of warfare.

The Dîn, or practical part of Islam, which contains the ritual and moral laws, inculcates as the chief duties the following four: prayer, almsgiving, fasting, and pilgrimage.

Prayer, 'the key of paradise,' comprises also certain religious purifications, as the most necessary preparations. They are of two kinds: the *Ghâsl*, or total immersion of the body, required as a religious ceremony on some special occasions; and the *Wudû*, a partial ablution, to be performed immediately before the prayer. This is of primary importance, and consists of the washing of hands, face, ears, and feet up to the ankles—a proceeding generally accompanied at each stage by corresponding pious sentences, and concluded by the recital of the 97th chapter of the Koran. If water be beyond reach, dry dust or sand may supply its place. 'The practice of religion being founded on cleanliness,' the ground or the carpet upon which the believer prays must be as clean as possible, and the use of a special prayer-carpet is therefore recommended. Every Mohammedan is obliged to pray five times in the space of every twenty-four hours. The prayer (Salât) itself consists partly of extracts from the Koran (Fard), partly of pieces ordained by the Prophet without allegation of a divine order (Sunnah). The first time of prayer commences about sunset; the second at nightfall; the third at daybreak; the fourth about noon; the fifth in the afternoon. The believers are not to commence their prayers exactly at sunrise, or noon, or sunset,

lest they might be confounded with the infidel Sun-worshippers. These several times of prayer are announced by the Muezzins (q.v.) from the minarets of the mosques. Their chant, sung to a very simple but solemn melody, sounds harmoniously and sonorously down the height of the mosque, through the mid-day din and roar of the cities, but its impressiveness is most strikingly poetical in the stillness of night. The day-call (the Adân) consists chiefly of the confession of faith ('God is most great,' 'Mohammed is God's apostle'; 'Come to prayer, come to security') repeated several times; the night-calls (Ula, the first; Ebed, the second), destined for persons who desire to perform supererogatory acts of devotion, are much longer. The believer often changes his posture during his prayers; and one series of such inclinations of head and knees, prostrations, &c. is called a Rukû. It is also necessary that the face of the worshipper should be turned towards the Kiblah, in the direction of Mecca, the exterior wall of the mosque marking that direction being distinguished by a niche (Mihrab). All sumptuous and pompous apparel is laid aside before the believer approaches the sacred place; and the extreme solemnity and decorum, the humility, the devotion which pervades it have been unanimously held up as an example to other creeds. The mosques are always open. Women, although not strictly forbidden to enter the mosque, yet are practically not allowed to pray there, lest their presence might be hurtful to true devotion. Besides these prayers, there are others ordained for special occasions, as on a pilgrimage, before a battle, at funerals, during an eclipse, &c. Moslems pray to God only, but implore the intercession of Mohammed, saints, and angels (see MOSQUE). Mohammedanism has no clergy in our sense of the word, the civil and religious law being bound up in one (see MOLLAH, MUFTI).

Next in importance stands the duty of giving alms. These are twofold—legal and voluntary, but the former, once collected by the sovereign, and applied to pious uses, has now been practically abrogated. The latter is, according to the law, to be given once every year, of cattle, money, corn, fruits, and wares sold, at about the rate of from two and a half up to twenty per cent. Besides these, it is usual to bestow a measure of provisions upon the poor at the end of the sacred month of Ramadân.

The duty of fasting follows (see FASTS). During the whole month of Ramadân the Moslem is commanded to refrain from eating, drinking, smoking, smelling perfumes, bathing, and every unnecessary indulgence in worldly pleasure, from daybreak until sunset. From that period till the morning he is allowed to eat, drink, and enjoy himself. The Arabian year consisting of twelve lunar months, it often happens that the Ramadân falls in mid-summer, when the fasting, more especially the abstaining from drinking, is excessively mortifying. None are exempt from this duty save the sick, travellers, and soldiers in time of war; but they are bound to fast an equal number of days during some other months. Nurses and pregnant women are entirely free from fasting. It is Mohammed's special and express desire that no one should fast who is not quite equal to it, lest he might injure his health and disqualify himself for necessary labour. Of the other commendable fast-days the Ashûra, on the 10th of Moharram, deserves special mention. There are very few Moslems that do not keep the Ramadân, even if they neglect their other religious duties; at all events, they all pretend to keep it most strictly, fasting being considered 'one-fourth part of the faith,' nay, 'the gate of religion.'—For the fourth paramount duty of the Mohammedan, the pilgrimage to Mecca, see MECCA.

With the 'positive' ordinances of Islam may also be reckoned the minor and greater festivals. The first (Al-Fetr, or 'breaking the fast'), following immediately upon the Ramadân, begins on the first day of the month of Shawâl, and lasts three days. The second (Eed Al-Korbân, or 'sacrifice') begins on the 10th of Dhu'l Hijjah, when the pilgrims perform their sacrifice, and lasts three or four days. The weekly day of rest is the Friday, because, from times long before Mohammed, the people used to hold public assemblies for civil as well as religious purposes on that day. When the special Friday service with its Chotbeh or Homily is over, the people are allowed to return to their worldly affairs; if they cannot afford to give themselves up entirely to pleasure or devotion for the rest of the sacred period.

The ancient rite of circumcision is used in Mohammedanism as the badge of the faith. It is commonly performed between the sixth and eighth year. Of the fundamental prohibitory laws of the Koran, one forbids the drinking of wine, which includes all strong and inebriating liquors, as giving rise to 'more evil than good'; and although of late, chiefly through European influence, very many Moslems have lost their religious scruples on that score, and not only secretly but openly indulge in spirits, yet the great bulk of the faithful refuse even to make use of the proceeds of the sale of wine or grapes. Some over-scrupulous believers even include opium, coffee, and tobacco in the prohibition; but general practice has decided differently. The prohibitory laws respecting food resemble closely those of Judaism; blood, the flesh of swine, animals that have died from disease or age, or on which the name of some idol has been invoked, or that have been sacrificed to an idol, or have been strangled, or killed by a blow, a fall, or by some other beast, are strictly forbidden. 'Pure' animals must be slaughtered according to certain fixed rules, and the name of God is to be invoked before the operation, without, however, the usual addition of the benevolent epithets. Fish, birds, and game are mostly allowed for food.

All games subject to chance, such as dice, cards, tables, bets, are considered so wicked that a gambler's testimony is invalid in a court of law. Chess and other games depending on skill, provided that they do not interfere with the regular performance of religious duties, and that they are played without any stakes whatsoever, are allowed by the majority of Moslem theologians. Usury is strictly prohibited. Taking interest upon any loan, however large or small, or profiting in trade through any questionable means, save by buying and selling, is severely condemned.

To prevent the faithful from ever falling back into idolatry the laws relating to images and pictures have been made very stringent. Whosoever makes an imitation of any living being, in stone, wood, or any other material, shall on the day of judgment be asked to endow his creation with life and soul, and, on his protesting his inability to do so, shall undergo the punishment of hell for a certain period.

The civil and criminal laws of Mohammedanism, founded both on the Koran and on the Traditions (*Sunnâ*), are in some instances, where the letter of the written or oral precept allows of various explanations, or where the case in question is not foreseen, interpreted according to the opinion of one of the four great masters of Islam—Abu Hanîfa, Malek Ibn Ans, Shâfeî, Ibn Hanbal—within the pale of their respective sects. The principal points, however, upon which all Mohammedans agree are the following. Polygamy is allowed. 'Take in marriage of the women who please you, two, three, or

four; but if ye fear that ye cannot act equitably, one, or those whom your right hands have acquired'—i.e. your slaves. Thus four wives, and a certain number of concubine slaves, is the extent to which a Moslem may legally go. The Prophet's example proves nothing to the contrary, since he was endowed with special privileges. It is moreover added, as an advice, that to marry one or two is quite sufficient for a man. A Moslem may, if urged by excessive love, or if unable to obtain a wife of his own creed, marry a Christian woman or a Jewess, but a Mohammedan woman is not, under any circumstances, to marry an unbeliever. In all cases, however, the child of a Moslem father, whatever the mother's faith, is a Moslem; nor does the wife that is an unbeliever inherit at her husband's death. A simple declaration of a man and woman at the age of puberty, before two witnesses, of their intention to marry each other, and the payment of part of the dowry (which is indispensable, and must amount to at least ten dirhems, or about five shillings) is sufficient for a legal marriage. A girl under age is given away by her natural or appointed guardian, with or without her consent. To see the face of any woman who is neither his wife nor his concubine, and who does not belong to any of the forbidden degrees, is strictly forbidden to the believer. Divorce is an easy thing for a Moslem husband. Twice a man may send away his wife and take her back again without any ceremony; the third time, however, or if he unite the triple divorce in one sentence at once, he dare not receive her again in wedlock until she have been married to another man in the meantime. Mere dislike is sufficient reason for a man to dissolve the conjugal ties, and his saying 'Thou art divorced,' or 'I divorce thee,' together with the payment of part of the wife's dowry, is all that is required from him by the law. A wife, on the other hand, is bound to her husband for ever, unless she can prove some flagrant ill-usage or neglect of conjugal duty on his part; and even then she forfeits part, or the whole, of her dowry. A woman proving disobedient to her husband may be declared by the *cadi* rebellious, and the husband is no longer bound to maintain her; but he cannot be forced to divorce her under these circumstances. If a slave becomes a mother by her master, and he acknowledges the child to be his own, the child is free, and the mother is to be emancipated at the master's death. A free person wishing to marry his or her slave must first emancipate this slave.

The privilege of primogeniture does not exist in the Mohammedan law, but males generally receive a double share. A person may not bequeath more than one-third of his property, unless there be no legal heirs. Children—whether begotten with the legal wife, or slave, or concubine, or only adopted—and their descendants are the first heirs; next come the claims of wives, parents, brothers, sisters, in their order. Where there is no legal heir the property falls to the crown. The law is very lenient towards debtors, the Koran recommending the creditor to remit a debt 'as alms.' Insolvency and inability to work for the discharge of the claim solve all further obligations. The most conscientious performance of all private contracts, however, is constantly recommended in the Koran.

Murder is punishable either with death or by the payment of a fine to the family of the deceased, according to their own pleasure. There must, however, be palliating circumstances in the latter case. Unintentional homicide is expiable by freeing a believer from slavery, and paying to the family a certain sum in proportion to the rank and sex of the deceased. He who has not the means of freeing a believer is to fast for two months, by way of penance. According to the strict letter of the law,

a man is not liable to capital punishment for killing his own child or an infidel; but, practically, no difference is generally made by civilised Mohammedan governments in our day: murder is punished with death, and no fine frees the culprit.

The Mosaic law of retaliation, in case of *intentional* wounds and mutilation, holds good also for Islam; that is (not, as has ignorantly been supposed, that the corresponding limb of the offender is to be cut off), a certain proportionate fine in money is to be paid to the injured. The payment for any of the single limbs of the human body, such as the nose, is the full price, the same as for a homicide; for a limb which is found twice, like hand or foot, half; for a finger or toe, the tenth part. Women and slaves have smaller claims. Injuries of a dangerous or otherwise grievous nature pay the full price; those of an inferior kind bring the perpetrator within reach of the lash or cudgel.

The Koran orders theft to be punished by cutting off the chief offending limb, the right hand; the second theft is punishable by the loss of the left foot; the third, of the left hand; the fourth, of the right foot; but the ordinary punishments of imprisonment, hard labour, and the bastinado have been substituted in our days. Not, however, if the property stolen were of easy access to the thief, nor if it consisted of food, since he may have taken this to satisfy the craving of his hunger.

Unchastity on the part of a woman was, in the commencement of Islam, punished by imprisonment for life, for which afterwards, however, stoning was substituted in the case of a married woman, and a hundred stripes and a year's exile in the case of an unmarried free woman; a slave to undergo only half of that punishment. Fornication in either sex is, by the law of the Koran, to be visited with a hundred stripes.

Infidelity, or apostasy from Islam, is a crime to be visited by the death of the offender, if he have been warned thrice without recanting. Equally severe, and not to be averted by repentance or revocation of any kind, is the punishment inflicted for blasphemy—against God, Mohammed, Christ, Moses, or any other prophet.

A further injunction of the Koran, for the carrying out of which the time has well-nigh gone by, is that of making war against the Infidels. He who is slain while fighting in defence and for the propagation of Islam is reckoned a martyr; while a deserter from the holy war is held up as an object of execration, and has forfeited his life in this world as well as in the world to come. At first all the enemies taken in battle were ruthlessly slain. Later, however, it became the law to give the people of a different faith against whom war was declared the choice of three things: either to embrace Islam, in which case they became Moslems at once, free in their persons and fortunes, and entitled to all the privileges of Moslems; or to submit to pay tribute—in which case they were allowed to continue in their religion, if it did not imply gross idolatry or otherwise offend against the moral law; or to decide the quarrel by the fortune of war—in which case the captive women and children were made slaves, and the men either slain, unless they became converts at the last moment, or were otherwise disposed of by the prince. The fifth part of the spoil belongs 'to God,' that is, the Sanctuary, to the apostle and his kindred, to the orphans, the poor, and the traveller.

In cases for which subsequent ages found no written rules laid down by the Prophet, traditional oral dicta were taken as the norm, and later still precedents of the califs were binding. Hence contradictions in theory and practice have crept in,

according to the different traditions and decisions of the Imáms or expounders of the Law, besides the various interpretations put upon the book itself within the pale of the different Mohammedan sects. The secular tribunals, therefore, not unfrequently differ in their decisions from the judicial tribunals; and the distinction between the written civil Law of the ecclesiastical courts and the common Law, aided by the executive power, is, fortunately for the cause of civilisation, getting clearer and clearer every day.

That part of Islam which has undergone least change in the course of time, and which most distinctly reveals the mind of its author, is also its most complete and its most admirable part—we mean the ethics of the Koran. They are not found, any more than the other laws, brought together in one, or two, or three Surahs, but 'like golden threads' they are woven into the huge fabric of the religious constitution of Mohammed. Injustice, falsehood, pride, revengefulness, calumny, mockery, avarice, prodigality, debauchery, mistrust, and suspicion are inveighed against as ungodly and wicked; while benevolence, liberality, modesty, forbearance, patience and endurance, frugality, sincerity, straightforwardness, decency, love of peace and truth, and, above all, trust in God and submission to His will are considered as the pillars of true piety, and the principal signs of a true believer. Nor must we omit to point out expressly that Mohammed never laid down that doctrine of absolute predestination which destroys all human will and freedom, because the individual's deeds cannot alter one iota in his destiny either in this world or in the next. So far from it, foolhardiness is distinctly prohibited in the Koran (ii. 196). Caution is recommended. And a glance at the whole system of faith, which is built on hope and fear, rewards and punishments, paradise and hell, destined to be man's portion according to his acts in this life, as well as the incessant exhortations to virtue and denunciations of vice, is sufficient to prove that the extreme doctrine of predestination is not in the Koran. But submission to the Lord's will, hope during misfortune, modesty in prosperity, and entire confidence in the Divine plans are supported by the argument that everything is in the hands of the Highest Being, and that there is no appeal against His absolute decrees.

That the worst side of Mohammed's character, the often wanton cruelty with which he pursued the propagation of his faith, should by his successors have been taken as a thing to be imitated is not wonderful if we consider how brilliant the results of the policy of the bloody sword had proved. The progress of the Moslem arms is described in the article KHALIF. Eighty years after Mohammed's death Islam reigned supreme over Arabia, Syria, Persia, Egypt, the whole of the northern coast of Africa, and over Spain; and notwithstanding the subsequent strifes and divisions in the interior of this gigantic realm, it grew and grew outwardly, until the Crescent was made to gleam from the spires of St Sophia at Constantinople (1453), and the war-cry, 'Lâ illâha ill Allâh!' resounded before the gates of Vienna (1529). From that time, however, the splendour and the power of Mohammedanism began to wane. Over two hundred millions, or 15 per cent. of the human race, profess Islam. Three-fourths of these are found from the Adriatic to farthest Malaysia, the rest mostly in North Africa. There are some 68½ millions of Moslems in India alone. Among the African races Mohammedanism has lately made great progress. Yet since it left off conquering it has lost also that energy and elasticity which promises great things. Its future fate will depend chiefly

on the progress of European conquest in the East, and the amount of Western civilisation which it will, for good or evil, import thither.

The strong points of Mohammedanism, its sobriety, its pure theism, its simple and intelligible creed, are heavily counterbalanced by its slavery, its degradation of woman, its stereotyping of laws and science, and its belief in the past rather than in the future. Yet it is strangely suitable for the Eastern mind.

Besides the Koran, the Sunna, and the native (Arabic, Persian, Turkish, &c.) writers on the foregoing subject, see the works of the European scholars D'Herbelot, Sale, De Sacy, Hammer-Purgstall, Burckhardt, Sprenger, Burton, Muir, Garcin de Tassy, Lane, Weil, Geiger, Nöldeke, Kremer, Margoliouth, Caetani, Snouck-Hurgronje; MacDonald, *Aspects of Islam* (1911); Bury, *Pan-Islam* (1919); Ameer Ali, *Mohammedanism* (1922); also the articles on ARABIA, KHALIF, CRUSADES, DEMONOLOGY, KORAN, MECCA, SENUSI, SHITES, SUNNITES, TURKEY, WAHABIS, and the great *Encyclopædia of Islam* (1905 et seq.).

Mohammed, the name of six sultans of Turkey, of whom the most noted is MOHAMMED II., the conqueror of Constantinople; born 1430, succeeded 1451, died 1481. See TURKEY.

Mohammerah (*Muhammrah*), a town of Arabistan, Persia, near the 'Iraq frontier, at the junction of the lower Karun with the Shat-el-Arab. It has about 12,000 inhabitants, and has become of commercial importance since the opening of the navigation of the Karun (q.v.) and the oil trade.

Moharram, or MUHARREM, the first month of the Mohammedan year, kept by the Shiite Mohammedans as a month of fasting and mourning, in commemoration of the sufferings of Hassan and Hussein (Hasan and Hosain), sons of Ali, the adopted son of the Prophet. A celebrated passion-play (Eng. version by Sir Lewis Pelly in 1879) is performed during this month in honour of the two saints at several towns in Persia and India.

Mohave Desert, a basin, with little water or vegetation, chiefly in the SE. of California, and extending into Arizona. The Mohave River rises in the San Bernardino range, and finally disappears in the Mohave Sink.

Mohawks. The Mohock or Mohawk Club, mentioned in the *Spectator* by Steele (No. 324) and Budgell (No. 347), was a scandalous club existing in London in 1711-12. 'The avowed design of their institution was mischief.' Gay mentions, in *Trivia*, that the Mohawks rolled women in hogsheads down Snowhill, and Swift told Stella of a report that eighty of them had been put into prison; while Lady Wentworth, writing to her son Lord Strafford, says, 'I am very much frightened with the fyer, but much more with a gang of devils that call themselves Mohocks.' A royal proclamation was issued against them 18th March 1712.

Mohawks. See IROQUOIS.

Mohic'ans, or MOHEGANS, a warlike sub-tribe of Delaware Indians, which in the 17th century settled in Connecticut, and afterwards helped the English against the French, and the colonists against the English. Of the few survivors, some remain at Norwich, and the rest are in Kansas and at Green Bay, Wisconsin. Their name has become widely known through Cooper's novel, *The Last of the Mohicans*.

Mohileff, or MOGILEFF, a town of White Russia, is situated on the right bank of the Dnieper, 95 miles SW. of Smolensk. It is the seat of a Greek and a Roman Catholic archbishop, their respective cathedrals dating from 1780 and 1692, and has an old castle, and a town-house built

in 1679. Tanning is the principal industry. Pop. 50,000, fully two-thirds being Jews. The town was burned down by Peter the Great for strategical reasons in 1708. Here on 23d July 1812 the French under Davout defeated the Russians under Bagration.

Mohileff, or MOGILEOFF, a town of Podolia, Ukraine, is situated on the left bank of the Dniester, 190 miles NW. of Odessa; pop. 30,000.

Mohl, JULES (1800-76), orientalist, was born at Stuttgart, and educated for the Lutheran Church at Tübingen. But at an early age he was irresistibly attracted to oriental studies, and in 1823 he betook himself to the famous Silvestre de Sacy and Rémusat at Paris. He was nominally professor at Tübingen from 1826 to 1833, but he lived all his life in Paris, becoming a member of the Institute in 1844, and professor of Persian at the Collège de France in 1847. He was long secretary to the Société Asiatique, and his admirably learned and luminous annual reports on the progress of oriental learning were collected by Madame Mohl, under the title *Vingt-sept Ans d'Histoire des Études Orientales* (2 vols. 1879-80). His great edition of the *Shāh Nāmah* was published in six folio volumes, from 1838 till 1868; a posthumous seventh volume, edited by Meynard, completed the gigantic undertaking in 1878.

Mohs, FRIEDRICH, German mineralogist, was born at Gernrode in the Harz Mountains 29th January 1773. He studied at Halle, at Freiburg school of mining, and in Austria. Professor of Mineralogy at Gratz in 1812, he removed to Freiburg as Werner's successor in 1817, and to Vienna as professor of Mineralogy and superintendent of the Imperial Cabinet in 1826. He died near Belluno 29th September 1839. Author of a *Grundriss der Mineralogie* (trans. 1825), he is best known for his scale of hardness, which has been much used for the identification of minerals. The scale is as follows: 1. Talc. 2. Gypsum. 3. Calcite. 4. Fluorspar. 5. Apatite. 6. Orthoclase. 7. Quartz. 8. Topaz. 9. Corundum. 10. Diamond. By hardness is to be understood resistance not to breaking but to scratching. Thus a mineral which will scratch calcite but not fluorspar has a hardness between 3 and 4. The finger-nail will scratch a mineral of hardness 2; a knife anything up to 5 with ease, 6 with difficulty. The hardness of a crystal may be different when tested in different directions on different faces; as a rule not much different, though kyanite ranges from 4 to 7. The method is a rough one, but not to be despised.

Mohun, CHARLES, fourth BARON (c. 1675-1715), dicer, brawler, and duellist, was tried in 1693 by his peers as an accomplice in the murder of the actor William Mountford, as the sequel to an attempt to abduct Mrs Bracegirdle the actress. Acquitted (apparently justly) of this and of another murder charge in 1699, he fought a duel with the Duke of Hamilton in 1712, in which both were killed. This affair is introduced in *Henry Esmond*.

Moidart. See INVERNESS-SHIRE.

Moidore, a former gold coin of Portugal, worth 27s. sterling.

Moir, DAVID MACBETH, a minor Scottish poet and humorist, was born at Musselburgh, 5th January 1798, and practised there as a physician till his death, 6th July 1851. He was much beloved by his friends for his amiability, and he earned a wide popularity, and made his pen-name of *Delta* (Δ) famous in Scotland at least by his verses contributed to *Blackwood's Magazine*. Of these a collection was made by Thomas Aird in 1852. Of more lasting merit is his genuinely humorous and still

popular *Autobiography of Mansie Wauch* (1828). Other books of less value were *Outlines of the Ancient History of Medicine* (1831) and *Poetical Literature of the Past Half-century* (1851).

Moira. See FATES, HASTINGS.

Moire (from the French verb *moirer*, to water silk in a large pattern, as distinguished from *tabiser*, to water or wave it in a small pattern), silks figured by the peculiar process called 'watering.' The silks for this purpose must be broad and of a good substantial make; thin and narrow pieces will not do. They are wetted, and then folded with particular care, to ensure the threads of the fabric lying all in the same direction, and not crossing each other, except as in the usual way of the web and the warp. The folded pieces of silk are then submitted to an enormous pressure, generally in a hydraulic machine. By this pressure the air is slowly expelled, and in escaping draws the moisture into curious waved lines, which leave the permanent marking called watering. The finest watered silks are known as *Moirs antiques*.

Moissac, a town in Tarn-et-Garonne, 111 miles SE. of Bordeaux; pop. 8000.

Moissan, HENRY (1852-1907), born at Paris, and professor of Chemistry from 1889, became very eminent as having isolated and liquefied fluorine, produced artificial diamonds, simplified the manufacture of acetylene, and reduced the refractory metals by the electric furnace. Among his works are one on fluorine and its compounds (1900) and *The Electric Furnace* (trans. 1904).

Mokanna, founder of a sect in Khorasan in the 8th century, was a soldier who, having lost an eye, was called Al-Mokanna, 'the veiled,' because to hide this deformity he constantly wore a veil, a habit attributed by his followers to the necessity of shrouding from the eye of the beholder the dazzling rays which issued from his divine countenance. Mokanna set himself up as an incarnation of God. Among other miracles, he is said to have caused a moon or moons to issue from a deep well. Mokanna found many adherents, and ere long he was able to seize upon several fortified places. But Almahdi marched against him, and after a long siege took his stronghold of Kash (780 A.D.), when, together with the remnant of his army, the veiled one took poison.

Mola di Bari, a seaport of Italy, on the Adriatic, 12 miles by rail SE. of Bari; pop. 16,000.

Mola di Gaeta. See FORMIA.

Molasses. See SUGAR.

Mold, a town of Flintshire, on the Alyn, in a rich mineral district, 11 miles W. by S. of Chester. Its fine 15th-century church is rich in stained glass. The county prison was sold in 1880 to expelled French Jesuits, who renamed it St Germanus' House, in memory of the 'Alleluia Victory' hard by (see GERMANUS). With Flint, &c., Mold till 1918 returned one member. Pop. (1921) 4659.

Moldau (Czech *Vltava*), the chief river of Bohemia, and an important tributary of the Elbe, rises in the Böhmerwald, on the south-west frontier, 3870 feet above sea-level, and flows south-east to Hohenfurt, thence northward to its confluence with the Elbe opposite Melnik. Its course to the point of confluence (278 miles) is longer than that of the Elbe, and the navigation of that river is greatly facilitated by the body of water which it contributes. It receives on the left the Wotawa and the Beraun, and on the right the Luschnitz and the Sazawa. The chief towns on its banks are Budweis and Prague. It becomes navigable from Budweis.

Moldavia, (1) formerly a principality, now the central northern division of Rumania (q.v.).—(2) An 'autonomous republic' (erected in October

1924) in south-west Ukraine, answering to parts of the old governments of Podolia and Kherson. Capital Balta.

Mole (*Talpa*), an Old World genus of Insectivores, with about eight species confined to Europe and Asia, all very like the Common Mole (*Talpa europæa*) which ranges from Great Britain (not including Ireland) to the Altai Mountains and Japan. The family Talpidæ includes the American Scalops, with webbed hind-feet, and the star-nosed Condylura. The aquatic long-tailed Desman (*Myogale*), which used to occur in Britain, is represented by two species, one in the Pyrenees and the other in south-east Russia. The family of Talpidæ goes back to the Upper Eocene, and the *Protalpa* of that remote age was less specialised for burrowing than the *Talpa* of to-day.

Characteristics of the Common Mole.—The plump, somewhat barrel-like body is well suited for burrowing; the pointed snout is effective in boring

Fig. 1.—Common Mole (*Talpa europæa*).

into the soft soil, and is supported by a cartilage ending in a little bone; the obliteration of the external ear-trumpet or pinna reduces friction; the eyes are hidden and protected among the fur. The short velvety fur has no 'set,' that is to say, the hairs rise vertically; it is therefore not inconvenient for the mole to move tail foremost in its burrow. There is no externally marked neck-region, but the neck-muscles are very strong and are used when the head tosses the earth. The old name 'mould-warp' refers to this action.

The pectoral girdle is very strongly developed,

Fig. 2.—Shoulder Girdle and Fore-limbs of the Common Mole:

s, shoulder-blade, or scapula; c, collar-bone, or clavicle; m, manubrium; h, humerus; u, ulna; r, radius; f, falciform or sickle-shaped bone of the wrist; i to v, the digits.

and there is a keel on the breast bone to which are fastened some of the powerful muscles used in burrowing. Very remarkable is the broadening and out-turning of the hand with its long nail-like claws; and in addition to the five digits there is an extra

'sickle-bone' to the inside of the thumb. With this powerful shovel the mole literally swims in the earth, and it can turn through 180° with four strong strokes. It is only from the wrist downwards that the fore-limb projects beyond the general contour of the body. The hind-limbs are built more delicately than the fore-limbs, and they are of more use in progression than in actual burrowing, though they help a little in scratching the earth backwards. The total length of the head and body is about $5\frac{1}{2}$ inches, and to that must be added $1\frac{1}{2}$ inches for the tail. Colour variations are not very uncommon, and include albino-moles without any pigment at all.

The teeth of the mole are 3 incisors, 1 canine, 4 pre-molars, 3 molars, on each side, above and below, making a total of 44, a common old-fashioned formula. More interesting is the long sharp upper canine, which helps in killing, and the presence of numerous mountain-top-like cusps on the crowns of the molars, which are admirably suited for crunching grubs and the like. The food consists chiefly of earthworms and insect-larvæ, and there is unusually rapid digestion. It is necessary for the restless animal to have a meal every few hours. Moles are also thirsty creatures, and there is often a well-marked run to the nearest water.

Moles are more active during the night, but they are sometimes to be seen burrowing near the surface in broad daylight, their back showing as they move along. Being subterranean as well as mainly nocturnal, they have little need of eyes for the ordinary purposes of vision. The eye is a minute black spot, about $\frac{1}{8}$ of an inch in diameter. It was described by Aristotle, who remarked that it had all the parts our eye has, except lids. As these are vestigial, the eye is permanently open. The lens of the mole's eye is imperfectly finished, and if any image is formed, it must be a blurred one. The optic nerve is somewhat degenerate. In all probability the chief use of the mole's eye is to distinguish light and darkness. The senses of touch, hearing, smell, and taste are keenly developed. The brain is of a somewhat primitive type. It will be evident from what has been said that the mole is a bundle of adaptations. It is suited through and through to the conditions of its life.

Habits of the Mole.—The burrowing is often very rapid; a tunnel of a hundred yards may be made in loose soil in a night. There is a twofold meaning in these burrows; they are made in the pursuit of food, and they serve as 'runs' around the nest, sometimes helping escape from enemies (which are not numerous), and sometimes leading to water. When the soil can be pushed to the sides, it is not necessary to form mole-hills, but in many places their formation is obligatory.

What is badly called the mole's 'fortress' is a large mole-hill, which serves for winter-quarters, and includes a comfortable grass-lined nest. There are runs radiating outwards and connected by circular tunnels, but there is no regularity of construction, and often very little intricacy. A fortress larger than usual is made by the female before she brings forth her young.

Pairing takes place above ground in spring, and soon afterwards the female makes the larger nest referred to, living quite by herself. Four or five young ones are brought forth from April onwards. They are naked and blind to start with, but they grow very rapidly, and are able to begin active life in about five weeks. The males are more numerous than the females, and there are fierce, sometimes fatal, encounters between rivals at the breeding season. There is no possibility of ranking the mole among monogamous mammals. But there is probably much to be still discovered in regard to

these matters. A subterranean animal is not a good subject for observation, and the mole's appetite is so exacting that captivity is seldom possible for more than a few days.

The mole is not a hibernator. If the ground is frozen it burrows more deeply than usual. Several observers, such as Ritzema-Bos, have given circumstantial accounts of stores of earthworms found, sometimes a spadeful together, near the mole's winter-quarters; and these may represent a last resource in very severe weather. They would not, of course, satisfy the mole's appetite for more than a short time. Ritzema-Bos noticed that the earthworms in the store he studied were all decapitated; and he interpreted this as a device for preventing them from crawling away. But it is necessary to gather more information in regard to the frequency of these stores and in regard to the general occurrence of decapitation. It may be mentioned that when a mole is beginning to devour an earthworm it bites the tail-end off, and then eats from the head, pressing with its paws on the worm so that the soil in the food-canal is squeezed out posteriorly.

Moles are often out of place, as on golf-courses and gardens. They are sometimes so numerous that they smother the pasture with their mole-hills, which should be scattered. Sometimes they spoil the teeth of the reaping machine or bring down a horse, as when William of Orange broke his collar bone. But they destroy large numbers of injurious insects and rather improve the soil than otherwise. Their fur is of considerable value, and they would not become too numerous if man did not destroy their natural enemies, the stoat and the weasel, the owls and hawks.

There is much that is attractive in this ancient mammal, and the balance, as regards utility or injuriousness, is quite certainly in its favour. Moles are highly specialised, beautifully adapted, extraordinarily active and strenuous, apparently very affectionate, and they should be encouraged within limits by relief from molestation.

The name, abbreviated from *Mouldwarp* or *Mouldwarp*, still provincially used, is derived from O. E. *molde*, 'mould,' and *weorpan*, 'to throw up.' Cf. Ger. *Maulwurf*. See conveniently, J. J. Simpson's *British Mammals*, 1924. For moles on the person, see NÆVUS; for masonry moles, see BREAKWATER.

Mole, MARSUPIAL. See NOTORYCTES.

Molé, MATTHIEU LOUIS, COMTE, statesman, descendant of Matthieu Molé (1584–1656), the mediator between the king of France and the parliament of Paris during the troubles of the Fronde, and son of Édouard Molé, president of the parliament in 1788, was born at Paris, 24th January 1781. His *Essai de Morale et de Politique* vindicated the government of Napoleon on the ground of necessity. The emperor appointed him Master of Requests, and eventually raised him (1813) to the dignity of a count, and to a place in the cabinet. Louis XVIII. made him a peer in 1815, and in the same year he was appointed minister of Marine. After Louis-Philippe ascended the throne he became minister of Foreign Affairs for a few months. In 1836 he succeeded Thiers as prime-minister; his ministry was unpopular, and in 1839 he appealed to the electors, but unsuccessfully. Henceforward he took little part in political affairs, except that after the revolution of 1848 he exerted himself, though in vain, to rally and unite the party of order in the Assembly, to which he had been elected. He died 23d November 1855. See *his Life and Memoirs*, ed. Noailles (trans. 1923 *et seq.*).

Mole-cricket. See CRICKET.

species which inhabits the sand-dunes of the coast.

Moleschott, JAKOB, physiologist, born at Boisle-Duc in Holland, 9th August 1822, studied medicine at Heidelberg, and taught there physiology, anatomy, and anthropology from 1847 until 1854, when he resigned his chair, the senate of the university having 'warned' him on account of the strong materialistic tendency of his writings. In 1853 he established a private laboratory and worked in it until 1856, when he was nominated professor of Physiology at Zürich; in 1861 he moved to the university of Turin, and in 1878 to that of Rome, where he died 20th May 1893. He wrote some twenty works, in German and Italian, on various branches of physiological research, including one on the *Natural History of Man and Animals* (1855).

Moleskin. See FUSTIAN.

Molesworth, MRS (Mary Louisa Stewart; 1839-1921), novelist and popular writer for the young, was born of Scottish parentage at Rotterdam, and her childhood was passed in Manchester and Scotland, and partly in Switzerland. She lived a good deal abroad. She began to write when very young, and her first attempts were published when she was only sixteen. She was most carefully educated under the superintendence of a very cultivated and accomplished mother, and she owed much to the instruction and direction of the Rev. William Gaskell, husband of the novelist. As 'Ennis Graham' she began at twenty-four to publish novels, and a few years later took foremost rank as a writer of children's stories. She also wrote lives of the saints for children, and stories to illustrate the Lord's Prayer.

Molesworth, SIR WILLIAM, the 'liberator and regenerator of Britain's colonial empire,' was born in London, 23d May 1810, of an old Cornish family, the Molesworths of Pencarrow, near Bodmin. He succeeded as eighth baronet in 1823; studied at Cambridge, at Edinburgh, and in Germany; made the tour of Europe; and sat in parliament for East Cornwall 1832-37, for Leeds 1837-41, and for Southwark from 1845 till his death on 22d October 1855, having accepted office in 1853 as First Commissioner of Public Works under the Earl of Aberdeen, and in 1855 as Colonial Secretary under Palmerston. He was the intimate friend of Bentham and James Mill, and was regarded as the parliamentary representative of the 'philosophical Radicals,' whose organ, the *Westminster Review*, he purchased in 1836, and merged with it the *London Review*, started a year before by him and Roebuck. A great admirer of Hobbes, he edited his complete works (16 vols. 1839-45) at a cost of £6000; but he will chiefly be remembered as having drawn attention to the abuses connected with the transportation of criminals, and as having pointed out the maladministration of the colonial office, and expounded the true principles of colonial self-government. Mrs Fawcett published a Life of him in 1901; and Mr E. Egerton edited in 1903 his *Select Speeches on Colonial Policy*.

Molfetta, a seaport and cathedral city of Southern Italy, on the Adriatic, 16 miles by rail N.W. of Bari; pop. 46,000.

Molière (JEAN BAPTISTE POQUELIN, who took this stage-name for reasons not apparent, and every point in whose imperfectly known life has been the subject of elaborate disquisition) was born at Paris, probably in the Rue St Honoré, and early in the year 1622. The house is not certain, and the exact date is unknown, though it appears to have been about the middle of January. His father was Jean Poquelin, his mother Marie Cressé, and the family came from Beauvais, there being no proofs of the Scottish origin which used to be asserted. Poquelin,

the father, was a substantial tradesman and *valet tapissier de chambre du roi*, an office combining the arrangement with the supply of furniture. The son was well educated, though the precise details of his education are very uncertain. He is supposed to have studied under the Jesuits at the Collège de Clermont, under Gassendi the philosopher, and under the regular teachers of law. He may have been called to the bar. His mother, who had some property, died when he was ten years old, and thus when he came of age he received his share of her fortune at once, becoming his own master. He declined to follow up his father's business (though it is said that he had already as his representative attended Louis XIII. on a royal progress as *valet tapissier*), hired a tennis-court, and embarked in theatrical affairs with the Béjart family and others, under the style and title of *L'Illustre Théâtre* (1643-46). This first venture lasted for over three years in Paris and failed. The company then proceeded to the provinces and had a sufficient amount of success to keep it going for twelve years, from 1646 to 1658, and to enable its manager to return triumphantly to the capital at the end of that time.

All the pains which have been spent on Molière's history have failed to elaborate any connected or detailed history of these long *Wanderjahre*. We hear most of the troupe at Lyons and in Languedoc; but its range must have been considerable, since it journeyed as far northwards as Rouen. The Prince de Conti (said to have been Molière's school-fellow) took it under his protection for a time, and Pézenas, near his Languedocian seat of La Grange, is one of the fixed points of Molière's biography. When, Conti having taken to Catholic Methodism, his protection failed, Molière succeeded in obtaining that of the king's brother, Philippe d'Orléans, so that his troupe became the servants of Monsieur. He was now in haste to return to Paris, where he at once received marks of royal favour, played before the king on October 24, 1658, and organised, first in the Petit Bourbon, then, on its demolition, in the Palais Royal, a regular theatre in competition with, if not in opposition to, those of the Hôtel de Bourgogne and the Marais.

During his sojourn in the provinces Molière had acquired considerable experience as a comic writer. Most of his work had been in a style not far removed from that of the old farces, and of this we have only two relics in *La Jalousie du Barbouillé* and *Le Médecin Volant*. But he had also written *L'Étourdi* and the *Dépit Amoureux*, and it is more than probable that some of his still greater work was at least on the stocks before his return to Paris. As a theatre manager he had to give tragedy as well as comedy: he is said to have been mistaken as to his own powers of tragic acting, and he had to depend for his tragedies on others. Corneille's *Nicomède*, with which he opened, was not a success; and though the other great tragedian of the day, Racine, was a personal friend of Molière's, their connection as manager and author was, not at all by Molière's fault, brief and unfortunate. But he did not tarry long before showing the immense resources which he possessed in his own talent as a comic writer. *Les Précieuses Ridicules*, the first essay of 'la bonne comédie,' as a famous story has it, dates, as far as publication is concerned, from November 1659; and from that time to his death on February 17, 1673, no year passed without one, and few years without more than one, of the greatest achievements in their own particular line that the world has seen. Except in one respect, the history of Molière during these fourteen busy years is the history of his work as an author, an actor, and a manager. But

the one exception is the most important incident of his life. In the spring of 1662 (perhaps on St Valentine's day, perhaps earlier or later, for the exact date, like almost everything else in this history, is disputed) Molière married Armande Claire Elisabeth Grésinde Béjart, an actress in his own company, probably about nineteen years old, and the youngest member of the above-mentioned family of Béjart, whereof two other sisters, Madeleine and Geneviève, and one brother, Joseph, had been members of the Illustre Théâtre. On this marriage scandal, both at the time and since, has exhausted itself. It was and still is, in the teeth not indeed of positive evidence, but of something nearly approaching thereto, maintained that Madeleine Béjart and Molière were not only comrades but lovers, that Armande was not Madeleine's sister but her daughter, even that Molière himself (this crowning calumny was, it seems, started by the jealousy of Montfleury, a rival actor and playwright) was the father of his wife. Not content with this imputation, later scandal asserted that Madame, or, as the time called her, Mademoiselle Molière, was unfaithful to her husband, and contemporary satire asserted that he was at any rate very jealous of her. Of this last there is, both from internal and external evidence, too much probability; of the graver charge there is as in the other case no evidence, while such evidence as there is is against it. It may be said before going further that Molière was during his whole life at Paris the butt of vehement animosities, professional and other; that before his death (1670) a sort of play, *Élomire Hypochondre* (Élomire = Molière), appeared, written by a certain Le Boulanger de Chalussay, with intent to take revenge for Molière's jests on doctors, which contains much spiteful tittle-tattle; and that long afterwards, in 1688, a venomous libel on his widow, entitled *La Fameuse Comédienne*, threw some mud at him in order to throw more on her. A kind of Molière-legend also sprang up, composed of stories such as the famous but apparently impossible tale of the *en-cas de nuit* or cold collation which Louis XIV. shared with Molière in order to overcome the prejudice of his aristocratic *valets de chambre*, that of the old woman to whom he is supposed to have read his plays, that (better grounded than the others) of the marquis who, angry at the actor's satire, rubbed Molière's head against the sharp buttons of his own coat in a feigned embrace, and so forth. Such authentic documents as we have show us a man well-to-do, though not above his work, well thought of by good judges, and living well. In August 1665 the king adopted Molière's troupe as his own servants. In 1667 symptoms of lung disease showed themselves in him, but were for the time checked. On the 17th February 1672 Madeleine Béjart, his comrade of thirty years, if nothing more, died. On the same day next year, after the seventh representation of his last play (see below), Molière died in his own house in the Rue de Richelieu of hæmorrhage from the bursting of a blood-vessel, having struggled through, as no imaginary sick man, the title-part. In person he is said to have had a good figure, but not a handsome face. His character would appear to have been extremely generous and amiable, though he seems to have certainly suffered from jealousy, and most probably from hypochondria. Nor is there discoverable in his work, or in anything reported of him, the least excuse for the accusations of irreligion which were brought against him, partly by private malice, partly as retaliation for the terrible attack on religious hypocrisy in *Tartuffe*, and for the misunderstood irony of *Don Juan*. The first-named piece was delayed five years before it could be completely played, and *Don Juan* was stopped and subjected to excisions.

Part of Molière's ill-fame in this respect was no doubt due to his earlier associations with Gassendi and to his fondness for that teacher's favourite classic, Lucretius, whose poem Molière himself is said to have translated as a whole.

The dates and titles of Molière's plays are as follows: *L'Étourdi*, *Le Dépit Amoureux* (1658; in the provinces two years earlier); *Les Précieuses Ridicules* (1659); *Sganarelle* (1660); *Don Garcie de Navarre* (1661); *L'École des Maris*, *Les Fâcheux*, *L'École des Femmes* (1662); *La Critique de l'École des Femmes*, *Impromptu de Versailles* (1663); *Le Mariage Forcé*, *La Princesse d'Élide*, *Tartuffe* (partially, 1664); *Le Festin de Pierre* [*Don Juan*], *L'Amour Médecin* (1665); *Le Misanthrope*, *Le Médecin Malgré Lui*, *Mélicerte*, *Le Sicilien* (1666); *Tartuffe* (fully, but stopped after first night, 1667); *Amphitryon*, *George Dandin*, *L'Avare* (1668); *Tartuffe* (at last fully), *Monsieur de Pourceaugnac* (1669); *Les Amants Magnifiques*, *Le Bourgeois Gentilhomme* (1671); *Les Fourberies de Scapin* (1671); *La Comtesse d'Escarbagnas*, *Les Femmes Savantes* (1672); *Le Malade Imaginaire* (1673). To this must be added part of *Psyché* (1671) in collaboration with Quinault and Corneille, the two farces above referred to (which are almost certainly his), attributed to him on the authority of J. B. Rousseau, a few arrangements of court masques, and some miscellaneous poems, the only important one being a copy of verses on Mignard's fresco-work at the church of Val de Grâce.

For posterity, however, Molière is nothing if not a comic dramatist; and the enormous majority of competent suffrages—a majority increasing as years go on—puts him at the very head of all writers of his own particular class. In France he is called a poet; but, though he could manage verse well enough when he chose to write in it, he is almost always best in prose, and his work possesses few, if any, of the more distinguishing and essential qualities of poetry. It is as a dramatist of manners—who more and more adjusted his art to the direct purpose of satirising and, if possible, reforming folly and vice, and who almost alone of all writers that have done this never sacrificed the art to the purpose—that he is absolutely unrivalled. Romantic or poetical comedy, like that of Shakespeare and Calderon, he hardly ever tried (almost the sole successful play in it being *Don Juan*), and it is not very probable that he would have frequently succeeded in it. The time made it impossible for him to be poetical like Aristophanes in subject, and his own genius did not incline him to be fancifully creative like Aristophanes in form. But in the sphere defined above he has no superior, and is very unlikely ever to have an equal. He gradually confined himself to it more and more closely, and always with the result of improvement. Nothing is more instructive than to compare *Les Précieuses Ridicules*, which is almost his first play, with *Les Femmes Savantes*, which is almost his last. They are so closely connected in subject that the later play has sometimes been called an expanded recast of the earlier. But the improvement in treatment is immense. Amusing as *Les Précieuses Ridicules* is, it is not much more than farce of the very best sort. *Les Femmes Savantes* is comedy of the highest kind, the result of exact observation of life informed by intimate knowledge of character, and clothed with the most accomplished phrase. Molière has sometimes been reproached with a leaning towards farce up to the last—exemplified not merely in such avowedly lighter plays as *Le Bourgeois Gentilhomme*, and the two satires on the provincial gentry, *Monsieur de Pourceaugnac* and *La Comtesse d'Escarbagnas*, but in passages of his more serious pieces. The objection shows a wholly erroneous conception of comedy

itself, and may be said to argue deficiency of humour in one direction. But the merely farcical side predominates, as undoubtedly as naturally in the earlier plays, the serious in the later. It is not till *L'École des Femmes*, perhaps not till *Le Misanthrope*, that the full genius of the author appears; and these two, with *Tartuffe*, *Le Festin de Pierre*, *Les Femmes Savantes*, *Le Malade Imaginaire*, and perhaps the admirable *Bourgeois Gentilhomme* as an example of the lower kind, may be said to be Molière's masterpieces. But from the *Dépit Amoureux* onward no play of his, not even the slightest, is without touches of his admirable wit, his astonishing observation, his supreme power over his own language, his masterly satire. It can hardly be said that any class of men or any prominent trait of mankind is spared by this satire, but undoubtedly three subjects—the vanity and levity of women, the frivolity of the nobles, and the pedantic professionalism of the learned classes, especially of medical men, have the largest share of Molière's lash. He has been accused of taking too low a view of human nature, but this again seems to come from a mistake in appreciating the conditions of his work. He also was and is accused of plagiarism; and it is quite true that in his early pieces especially he avails himself of existing canvas for his own embroidery freely. The best defence of the practice is the boldest: that any man who can embroider like Molière does only too well to requisition canvas where and to what extent he likes. Of another, a subtler, and a less easily refuted observation—that, admirable as his criticism of humanity in general is, his characters tend too much to types, and are lacking in the individuality which Dante and Shakespeare give—we have no room to speak fully. Indeed, much more space than can be here afforded would be insufficient to discuss even most briefly the various aspects of his genius. We must content ourselves with saying that of all French writers he is that one whose reputation stands highest by the combined suffrage of his own countrymen and of foreigners, that at his best he keeps the stage with perfect ease and success after two hundred years, and that he is almost everywhere delightful in the study for his wonderful truth to nature and his not less wonderful expertness in art.

The bibliography of Molière is very voluminous. The first complete edition of his work was edited in 1682 by his comrades, La Grange and Vinot. By far the best, complete as to text, with life, lexicon, bibliography, &c., is that of Despois and Mesnard in the series of 'Les Grands Écrivains Français' (13 vols. 1873-1900). There are excellent editions of the dramatist's works by Anatole France in the 'Collection Lemerre' (7 vols. 1876-91), with notes by G. Monval in the 'Bibliothèque des Bibliophiles' (8 vols. 1882). There are translations by Van Laun (1875-77) and Heron Wall (1876-77). From 1870 to 1889 there existed a special periodical called the *Moliériste*. M. Loiseau's *Points Obscurs de la Vie de Molière* caused discussion; an excellent collection of studies will be found in M. Larroumet's *La Comédie de Molière*. The Life prefixed to the above-named 'Grands Écrivains' edition may be regarded as a complete digest of the whole subject. Other Lives are those of Taschereau (4th ed. 1851), Claretie (1873), Mahrenholtz (Heilbronn, 1881), Moland (1886), Desfeuilles (Paris, 1900), Schneegans (Berlin, 1901), Hatton (1905), H. M. Trollope (exhaustive but not popularly written, 1906), Chatfield Taylor (1907), Brander Matthews (1911); and the volume on 'Molière and his Times' (1906) in Mantzius's *History of Dramatic Art*.

Molina, JUAN IGNACIO (1740-1829) Jesuit missionary and botanist, born at Talca in Chile, died at Bologna. He wrote a natural history of Chile and discovered many plants. A genus of grasses, *Molinia* (with one British species *M. caerulea*), is named after him.

Molina, LUIS, a celebrated Spanish Jesuit theologian, was born at Cuenca, in New Castile, in the year 1535, and, having entered the Jesuit Society in his eighteenth year, studied at Coimbra, and was appointed professor of Theology at Evora, where he continued to teach for twenty years. He died at Madrid, 12th October 1600. Molina's celebrity is mainly confined to the theological schools. His principal writings are a commentary on the *Summa* of St Thomas Aquinas (1593); a minute and comprehensive treatise, *De Justitia et Jure* (1592); and the celebrated treatise on the reconciliation of grace and free-will (*Liberi Arbitrii cum Gratiae Donis . . . Concordia*), which was printed at Lisbon in 1588, with an appendix, printed in the following year. The problem which the latter work is meant to resolve is almost as old as the origin of human thought itself, and had already led, in the 4th century, to the well-known Pelagian controversy (see PELAGIUS). In reconciling with the freedom of man's will the predestination of the elect to happiness, and of the reprobate to punishment, Molina asserts that the predestination is consequent on God's foreknowledge of the free determination of man's will, and, therefore, that it in no way affects the freedom of the particular actions, in requital of which man is predestined whether to punishment or to reward. God, in Molina's view, gives to all men sufficient grace whereby to live virtuously, and merit happiness. Certain individuals freely co-operate with this grace; certain others resist it. God foresees both courses, and this foreknowledge is the foundation of one or the other decree. This exposition was at once assailed in the schools on two grounds—first as a revival of the Pelagian heresy, inasmuch as it appears to place the efficacy of grace in the consent of man's will; second, as setting aside altogether what the Scriptures represent as the special election of the predestined. Hence arose the celebrated dispute between the Molinists and the Thomists—both of whom, however, maintained that, in all circumstances, the will remains free, although they may fail to explain how this freedom is secured under the action of efficacious grace. It was first brought under the cognisance of the Inquisitor-general of Spain, by whom it was referred to Pope Clement VIII. This pontiff, in 1598, appointed the celebrated congregation *De Auxiliis* to consider the entire question; but, notwithstanding many lengthened discussions, no decision was arrived at during the lifetime of Clement; and although the congregation was continued under Paul V., the only result was a decree in 1607, permitting both opinions to be taught by their respective advocates, and prohibiting each party from accusing the adversaries of heresy. The dispute, in some of its leading features, was revived in the Jansenist controversy (see JANSEN). Molinism has been commonly taught in the Jesuit schools. See AQUINAS, SUAREZ.

Molina, TIRSO DE. See TELLEZ.

Moline, a city of Illinois, on the Mississippi, 179 miles by rail W. by S. of Chicago, and separated from Rock Island only by a swift and narrow channel affording great water-power, which is utilised by means of a dam. There are many busy mills and factories. Pop. 31,000.

Molinos, MIGUEL DE, was born of noble parentage at Patacina, near Saragossa, 21st December 1640. He received holy orders and was educated at Pampeluna, and afterwards at Coimbra. At Rome he soon acquired a high reputation as a director of conscience and a master of the spiritual life. An ascetical treatise which he published, under the title of *Guida Spirituale*, added largely to the popularity which he had acquired in his

personal relations; but there were not wanting many who, in the specious but visionary principles of this work, discovered the seeds of a dangerous and seductive error. Among these the celebrated Jesuit preacher Segneri was the first who ventured publicly to call them into question. By degrees reports unfavourable to the practical results of this teaching, and even to the personal conduct and character of Molinos, or of his followers, began to find circulation; and eventually, in the year 1685, he was cited before the Holy Office, and submitted to close imprisonment and examination. In addition to the opinions contained in his book, a prodigious mass of papers and letters, to the number, it is said, of 20,000, found in his house, were produced against him, and he was himself rigorously examined as to his opinions. The result of the trial was a solemn condemnation of sixty-eight propositions, partly extracted or inferred from his *Spiritual Guide*, partly, it would appear, drawn from his papers or his personal professions. These doctrines Molinos was required publicly to abjure, and he was himself sentenced to close imprisonment, in which he was detained until his death, 28th December 1697. The opinions imputed to Molinos may be described as an exaggeration of the principles of Quietism (q.v.)—the utter indifference of the soul, in a state of perfect contemplation, to all external things. See John Bigelow's *Molinos the Quietist* (New York, 1882); J. H. Shorthouse, *Golden Thoughts from the Spiritual Guide* (1884).

Molise. See CAMPOBASSO.

Mollendo, a port of Peru, lying SW. from Lake Titicaca. It has railway connection with Cuzco and with Lake Titicaca and La Paz (by a line passing Arequipa and crossing the Andes at a height of 14,660 feet), and enjoys considerable trade. Pop. 10,000.

Mollusca, a large division (or phylum) of Invertebrate animals, including three chief classes: (1) Lamellibranchs, Pelecypods or bivalves; (2) Gasteropods, snails and slugs of many kinds; and (3) Cephalopods, cuttle-fishes and the Pearly Nautilus. Another class (Scaphopods) seems to be required for the cylindrical Elephant's Tooth Shells (Dentalium); and there are a few primitive types—e.g. Neomenia and Chetoderma—which are regarded by many zoologists as forming a fifth class (Solenogastres). Of the three chief classes constituting the phylum Mollusca, the bivalves are divergent from the others in having an undeveloped head-region and no rasping-ribbon or radula in the mouth.

There is great diversity in the form of the body in molluscs; but there is this in common, that segmentation is conspicuous by its absence. Segments are suggested by the eight shell-plates of Chitons, but this is a quite superficial feature. The symmetry of the body is bilateral in Lamellibranchs and Cephalopods, but in most Gasteropods the body is unsymmetrical or lop-sided. The primitive Chitons and Solenogastres are bilateral, and a secondary bilaterality appears in the free-swimming pelagic Gasteropods known as Pteropods or sea-butterflies. Another general feature which marks off molluscs from Arthropods is the absence of anything in the nature of limbs. Very characteristic is the so-called 'foot,' a muscular development of the ventral surface. Its primitive form was probably a flat, creeping sole, as in Chiton. This condition persists in many Gasteropods, and in some simple Lamellibranchs like Solenomya. But in most Lamellibranchs it becomes wedge-shaped or ploughshare-like (to which the term Pelecypod, 'hatchet-footed,' refers), and in Cephalopods it seems to form the 'arms' around

the mouth and a siphon or funnel through which water is expelled. Another distinctively molluscan feature is the mantle, a single or double fold of skin, arising from the dorsal surface, which encloses a space (the mantle cavity) in which gills usually lie. Typically the mantle secretes the shell, but both mantle and shell may be absent. In most Lamellibranchs the mantle is drawn out posteriorly to form a double tube or siphon through which water enters and leaves the body. The water-current brings in food-particles, and some bivalves use their siphon in actively searching for nutriment. In many Gasteropods there is a single respiratory siphon. In the land-snails the mantle cavity has become a pulmonary chamber for breathing dry air. In Cephalopods the mantle is strong and muscular, and helps in locomotion. While there are active molluscs like the squids, molluscs are, on the average, relatively sluggish, and with this is to be associated the abundance of unstriated muscle. The more rapidly contracting muscles have cross-striated fibres as usual, or fibres with unstriated fibrils twisted in a spiral. As to diet, the Cephalopods are voracious carnivores, as their prehensile suckers, parrot-beak jaws, and powerful radula suggest; the Gasteropods include thorough-going carnivores able to bore through hard shells, and thorough-going vegetarians, some with a wide and others with a very specialised appetite; the Lamellibranchs subsist on minute organisms and particles of detritus.

On the dorsal surface of the molluscan larva there is usually a small sac in which a transient primary shell is formed. The permanent shell is a cuticular product of the mantle. It consists of an organic basis of conchlin (or conchiolin) and of carbonate of lime associated therewith. The outermost layer of the shell (periostracum) is typically of pure conchlin; the next layer (prismatic) has the lime disposed in prisms; the innermost layer (nacreous or mother-of-pearl) has the lime in fine lamellæ, and often shows iridescence. The parallel lines on shells indicate periods of growth. There are three main types of shell: the bivalve shell of Pelecypods; the typically spiral, unsymmetrical, and unchambered shell of most Gasteropods; and the chambered shell of Nautiloids and Ammonoids coiled in one plane. There are numerous peculiar types, such as the eight plates of Chitons, the

Fig. 1.—Section of Schematic Mollusc (from Lankester). m, mouth; g.c. cerebral, g.pl. pleural, g.pe. pedal, g.v. visceral ganglia; p, foot; a.l. left lobe of digestive gland; k, genital opening; n, posterior end of the foot; c, edge of the mantle; u, kidney; f, edge of primary shell-sac; v, ventricle of the heart; s, pericardial cavity.

tube of Dentalium, the cone of limpets, the strange secondary tube of Aspergillum (q.v.), and so on. A reduction or absence of shell is seen in land-slugs, some Pteropods and Heteropods of the open sea, all the Nudibranchs of the shore, and in all the living Cephalopods except the Pearly Nautilus. Arion (the Black Slug), Clio (a Pteropod), Pterotrachea (a Heteropod), and Octopus (a Cephalopod), may be mentioned as types with no shell in the adults.

Among the more technical general characters

the following are the most important. The nervous system consists of three chief pairs of ganglia—cerebrals, pedals, and pleurals—with connecting circum-oesophageal commissures, and there is also a visceral system consisting typically of (a) a loop connecting the two pleurals and provided with two visceral ganglia, and (b) a stomatogastric loop passing from the cerebrals beneath the gullet and provided with two buccal ganglia. A portion of the true body-cavity or coelom usually persists, at least as a pericardial chamber around the heart, and communicates with the exterior through a nephridium or two nephridia. The rest of the cavity of the body is hæmocœlic, corresponding to enlarged blood-channels. The heart typically consists of a ventricle and two auricles, and there are usually well-developed blood-vessels; part of the circulation, however, is in most cases lacunar, i.e. in ill-defined channels. Respiratory organs are typically represented by gills or ctenidia situated in the mantle cavity, consisting of an axis attached to the body and bearing lamellæ. But the gills may have simpler forms, or may be absent altogether, in which case the mantle takes on respiratory functions, as in the fringed margin of the limpet or the 'lung' of terrestrial snails and slugs. In the higher Lamellibranchs the gills form two great basketwork-like ciliated plates on each side of the body between the foot and the mantle, and are of great importance in wafting food-particles to the mouth. In those marine Gasteropods in which the typical gills have been suppressed there may be 'adaptive gills' in the form of branching processes of the body wall, as in many Nudi-branchs. At the base of the gills there is generally a paired or unpaired olfactory organ, called the osphradium. The sexes are always separate in Cephalopods, usually separate in Lamellibranchs, but a large number of Gasteropods are hermaphrodite, e.g. all the terrestrial snails and slugs.

There are two common larval stages among molluscs—the trochophore and the veliger. The trochophore or trochophore is a minute, free-swimming, pear-shaped or barrel-shaped, larva, with a curved gut and a ring of cilia in front of the mouth. Great interest attaches to its occurrence in molluscs, for it is also the characteristic larva of Annelid worms. Different as is the adult structure in these two groups, there is a very striking resemblance in the early stages of development. A trochophore larva is exhibited by many Gasteropods and Lamellibranchs, and also by Dentalium. It is probably representative of an ancestral type common to Annelids and Molluscs. The trochophore larva, among Gasteropods,

Fig. 2.—Earlier (A) and later (B) 'Veliger' of a Gasteropod (after Gegenbaur).
a, velum; b, foot; c, visceral dome.

Lamellibranchs, and Scaphopods, usually changes into the second larval stage or veliger, marked by an effective locomotor structure, the ciliated velum, which is often produced into mobile lobes, by the beginnings of foot and mantle, and by a minute shell-gland on the dorsal surface. In short, there is an anticipation of the varied adult conditions, and the characters are definitely molluscan, not ancestral. In cuttle-fishes there is neither trochophore nor veliger, and the development is direct

and condensed, a fact associated with the large store of nourishment in the egg. An analogous suppression of larval stages is seen in the terrestrial snails. The fresh-water mussels (Unionidæ) have a peculiar kind of larva (glochidium), which is without mouth, velum, and foot, but has a bivalve shell with marginal teeth on each valve. It is liberated from the parent when a fresh-water fish (sometimes one particular species) is in the vicinity. To this the larva may manage to attach itself, and if it is successful it undergoes a metamorphosis on its temporary host, and falls off after attaining the adult form.

Lamellibranchs are represented by a few rarities in the Lower Cambrian; they are still rare in the Ordovician; they are greatly increased in the Silurian; and thence onwards there is abundant fossil representation. Elephant's Tooth Shells (Scaphopods) begin with a few forms in the Ordovician, increase slowly until the Cretaceous, and after that rapidly. The Chitons, which are primitive Gasteropods, make their appearance in the Ordovician, are rare in the Silurian and Devonian, more abundant in the Carboniferous, and go on increasing. Gasteropods have gone on increasing in number from the Cambrian until to-day. Of the Tetrabranchiate Cephalopods the Nautiloids began in the Ordovician, and have only one living representative, the Pearly Nautilus; the Ammonoids began in the early Devonian, reached their climax in the Trias, and did not survive the close of the Cretaceous. The Dibranchiate Belemnoids appeared in the Trias, culminated in the Lias and Cretaceous, and then waned rapidly (Spirula is regarded by some as a living representative); the Sepioids began in the Lias, the Octopods in the Late Tertiary.

For anatomy, see Pelseneer in Lankester's *Treatise on Zoology*; for natural history, see Cooke in *Cambridge Natural History* (vol. iii. 1895); for classification, see Woodward's *Manual of the Mollusca* (1875); for palæontology, see Eastman's edition of Zittel's *Textbook of Palæontology* (vol. i. 1900); for development, see MacBride, *Textbook of Embryology* (vol. i. 1914).

Mollwitz, a village of Lower Silesia, 7 miles W. of Brieg. An obelisk (1878) marks the battlefield where 20,000 Prussians (though Frederick himself fled) defeated an equal number of Austrians under Marshal Neipperg, 10th April 1741. The Austrians lost 5340 men, the Prussians 5500.

Molly. See FULMAR.

Molly Maguires, an Irish secret society which during the ten years preceding 1877 terrorised the coal regions of Pennsylvania. The name was imported from Ireland, where it had been adopted by a branch of the Ribbonmen whose outrages by night were perpetrated in female disguise (cf. Trench's *Realities of Irish Life*, p. 82). The object of the organisation in Pennsylvania appears to have been to secure for its members, as far as possible, the exclusive political power in the eastern part of the state. Murders were committed in the open day, though much more usually by night; and the terror of the society was on all the coal country until, in 1876-77, a number of the leaders were convicted and executed on the evidence of a detective who joined the society.

Molmenti, POMPEO GHERARDO, born in Venice in 1852, became a lawyer and then professor of Literature in his native city, and has written important works on Goldoni and Fogazzaro, on Giorgione and Carpaccio, as well as on the history of Venice.

Moloch, or more properly MOLECH, is mentioned in 1 Kings, xi. 7, as the 'abomination of the children of Ammon,' and occurs frequently elsewhere in the Old Testament as the name or title of a divinity occasionally worshipped in the kingdom of Judah

with cruel rites. The Hebrew form of the word is invariably *Molech*, almost always with the article ('the Molech'); *Moloch* in the Authorised Version has come through the Septuagint and Vulgate. The word means 'king,' and is the same (*melech*) as appears in the title Melkarth (Malk-kart, Melicertes) applied to the Tyrian Baal, and in a large number of compound divine names in Semitic inscriptions; the change from *Melech* to *Moloch* is due to the later Jews, who gave the word in this connection the vowel-points of *Bosheth* ('shameful thing'; cf. Ishbaal, Ish-bosheth). Of *Moloch* as a deity of the Ammonites nothing special is recorded, and it is not improbable that in 1 Kings, xi. 7, the only place where he is spoken of as such, the kindred word *Milcom* or *Malcam* ought to be read (see the LXX. and compare 1 Kings, xi. 5, 33; 2 Kings, xxiii. 13; Jer. xlix. 1, 3; Zeph. i. 5). In any case the worship of the Ammonite deity in the days of Solomon was essentially distinct from the *Moloch* worship which at a later date came to be practised in Judah, especially in times of great calamity. The first recorded instance of a worshipper of Jehovah 'making his son to pass through the fire to *Moloch*' is that of Ahaz (2 Kings, xvi. 3). The same story is told of Manasseh (2 Kings, xxi. 6), and that the practice had become a common one in the course of the 7th century is shown by frequent allusions in Jeremiah, Ezekiel, and the Book of Leviticus. The victims were slain at the sanctuary (Jer. xix. 4), and afterwards burned as holocausts on a 'tophet' or pyre in the valley of Hinnom (Ge-Hinnom, Gehenna) near Jerusalem (2 Kings, xxiii. 10; Jer. vii. 31, 32; xix. 6, 13, 14); the often quoted description by Rabbinical writers of a calf-headed brazen image of *Moloch*, in which the children were burned alive, is mere invention. On the general question of the origin of human sacrifice, see SACRIFICE. It is probable that the ritual of *Moloch* worship was borrowed by the people of Judah from one or other of the surrounding nations; it was practised, we know, by the Moabites (2 Kings, iii. 27). At Jerusalem it has been held that it was intended to propitiate Jehovah, regarded as the national '*Moloch*' or '*Baal*' or '*King*,' though the prophets speaking in Jehovah's name constantly denounced it as unsanctioned by him (see Jer. vii. 31; xix. 5). See J. G. Frazer, *Adonis, Attis, Osiris* (1914, pp. 219 seq.).

Moloch (*Moloch horridus*), an exceedingly spiny Australian lizard, blotched with orange, red, and black, and covered all over with horny warts and

Moloch horridus.

sharp spines, which give it a grotesque appearance, concealing, however, an inoffensive character. It is sluggish in its movements, attains a length of 10 inches, and is found chiefly in central and West Australia.

Molokai (the Lepers' Island) is situated in the middle of the Hawaiian group to the S.E. of Oahu; area, 261 sq. miles. Between the harbour of Kalaupapa and the *pali* (2000 to 3000 feet) lie fertile pasture lands and the settlements into which the leper colony is divided. Here it was that Father Damien (q.v.) laboured.

Molossians, the most important people of ancient Epirus (q.v.).

Moltke, HELMUTH, COUNT VON, field-marshal of the German empire, who as chief of the general staff at Berlin planned the Prussian campaign of 1866 against Austria, and the German campaign of 1870-71 against France. He was born 26th October 1800, at Parchim in Mecklenburg-Schwerin, his father being a general in the Danish army, of a good old family and considerable wealth. In 1812 he was, with his only brother, sent to the military academy at Copenhagen, where he remained under the strictest discipline for six years, and distinguished himself in the scientific branches of military study. In 1819 he became lieutenant in a Danish regiment, and in 1822 entered the Prussian service. His parents having by this time lost the whole of their property from war and misfortune, he had to undergo many hardships in order to maintain himself on the slender pay of a Prussian officer, and at the same time obtain instruction in various foreign languages. In 1832 Moltke was appointed to the staff, and for three years he continued to develop by scientific and exact study his extraordinary powers of combination and organisation. He then obtained leave to travel, and, arriving in Turkey at a critical moment, he was entrusted by the sultan with the task of remodeling the Turkish army, and remained with Mahmoud II. as military adviser till October 1839, when he returned to his old position at Berlin. From 1858 to 1888 he was chief of the general staff in Berlin, and he at once commenced the reorganisation of the Prussian army. He also elaborated plans for the defence of the German coasts, and the creation of a German navy. His wonderful strategical power was displayed in the wars with Denmark in 1863-64, with Austria in 1866, and with France in 1870-71, bringing them all to triumphant issues. He married in 1845 the daughter of an English gentleman residing in Holstein, but had no family. Known as 'The Silent,' he was a man of great modesty and simplicity of character. His ninetieth birthday was the occasion of numerous honours. He died 23d April 1891.

He wrote a series of letters from Turkey, and an account of the Russian campaign in Turkey in 1839 was published in 1841. His *Letters from Russia*, written in 1856 to his wife, were published in 1877 (Eng. trans. 1878). Histories of the Italian campaign of 1859, the Danish-German war, the Austro-Prussian war, and of the Franco-German war were prepared by the general staff under his direction. In 1891-93 an edition of his works in six vols. was published, containing biography, a novel, a short history of the Franco-German war (Eng. trans. 1892), letters to his mother and brothers (Eng. trans. 1892), speeches and reminiscences. See also *Lives* by Wilhelm Müller (Eng. trans. 1879), F. von Köppen (1888), Müller-Bohn (1889), and Mary Herms (Eng. trans. 1892).—Moltke's nephew, HELMUTH (1848-1916), likewise rose to be Chief of the General Staff in 1906, but was superseded by Falkenhayn early in the Great War (December 1914). See *Erinnerungen: Briefe: Dokumente* (1923).

Molucca Beans. See GUILANDINA.

Moluccas (also called SPICE ISLANDS), the easternmost division of the Malay Archipelago, comprising most of the islands between Celebes and New Guinea west and east, and between Timor and the Philippines south and north. Originally the term *Molucos* was applied by the Portuguese

only to the small islands (Ternate, Tidor, &c.) west of Jilolo, which are now known as the *Little Moluccas*; but it was gradually extended to Jilolo itself, to Buru, Ceram, and all the spice-growing islands of the eastern seas, which, with part of New Guinea, now form politically the Dutch residency of *Amboyna*. Physically they fall into the two groups of the *Northern Moluccas*, disposed in the direction from north to south, and the *Southern Moluccas*, running mainly west and east. The northern group, which is surrounded on all sides by deep waters, ranging from 500 to 2000 fathoms, lies between the Molucca and Jilolo passages west and east, and comprises Morotai (Morty) and Rau (Riao) in the north, Jilolo, Ternate, Tidor, and other islands in the centre, Batchian (Batjan), Tawali, Mandioli, and Great and Little Obi (Oby) in the south, with a total area of nearly 10,000 sq. m., of which Jilolo has 7000, Morotai 1100, and Batchian 850.

The Southern Moluccas are connected by a submarine bed of less than 100 fathoms westwards with Sula and Celebes, but are separated from the northern group by an abyss of over 1500 fathoms, and are washed on the south side by the Banda Sea, which has a depth of 3000, and at one point (near the Banda volcano) of over 4000 fathoms. They comprise the two large islands of Buru (8500 sq. m.) and Ceram (7000), the small Amboyna, Uliasser, Banda, and Ceram Laut sub-groups, the outlying Ké (Kei) and Aru clusters, with some other islands scattered over the neighbouring waters. The people are chiefly Orang-Malayu, or civilised Malays, in the Little Moluccas, Banda, and Amboyna, elsewhere the so-called 'Alfuros'—i.e. uncivilised or non-Mohammedan natives, some Indonesians, some true Malays, some mixed Malayo-Papuans (see MALAYS).

The Moluccas lie partly on the line of the great volcanic fault, which sweeps round in a vast curve from Sumatra to the Philippines and Japan, and in the Moluccas is indicated by the still active Gunong-Api (1870 feet) in Banda, Tidor (5730), Ternate (5650), Motir (2800), by three cones in Jilolo, Tolo in Morotai. Api was the scene of a terrific eruption accompanied by earthquakes in 1825; Ternate is one of the most restless volcanoes in Malaysia; and several other cones appear to be of relatively recent date. A former union with Celebes and the Philippines best explains the many features common to their natural history. The trachitic Morotai was certainly at one time connected with Jilolo, and were the connection restored the resemblance would be complete between the curiously shaped islands of Celebes and Jilolo, which have been compared to a mutilated starfish. Jilolo, also called Halmahera, or the 'Great Land,' largely consists, like Ceram and Buru, of crystalline or metamorphic and very old sedimentary (coralline limestone) rocks, whereas Ternate, Tidor, Banda, and the smaller members of the group are partly of igneous, partly of coralline origin.

Despite their tropical position, being nearly bisected by the equator, the Moluccas enjoy a relatively healthy climate, and in some places the European race (Portuguese and Dutch) has even been acclimatised. The excessive heats are everywhere tempered by sea-breezes and by the mountainous character of the islands, which in Buru and Ceram rise to heights of 8000 and even 10,000 feet. In the Southern Moluccas the north-east trades prevail from May to October, and are accompanied by heavy rains and thunderstorms. They are followed by the west monsoon, which has already discharged most of its moisture before reaching this region. In the north the regular winds become intermingled, with the result that the seasons are here extremely variable, fine and wet weather alter-

nating throughout the year. But the temperature oscillates everywhere within very narrow ranges, seldom rising above 85° or falling below 75° F. on the coast-lands. Rainfall, 150 inches at Amboyna.

Indigenous to most parts of this region are the clove, nutmeg, and other species, although these plants are now cultivated only in Amboyna and the Banda group; elsewhere they were extirpated by the Dutch government with the view of increasing the value of the Banda plantations, and preserving the monopoly of the spice trade. Other valuable plants are the sago-palm, which supplies the staple food of the Moluccas; the pandanus, remarkable for its aerial roots, the canary nut, dammar pine, and Cajeput (q.v.).

In its fauna the Molucca group is connected with Celebes by the Babiroussa (q.v.) found in Buru, and with New Guinea by the birds of paradise (Batchian), the marsupial cuscus and flying opossum occurring in several islands. Here are also found the cassowary, the Australasian megapodius, or mound bird, the crimson lory, the racket-tailed kingfisher, and numerous species of parrots and pigeons of gorgeous plumage. Insects, such as the long-armed beetle of Amboyna and several butterflies, here attain their largest size and display their brightest colours. The shallow waters, especially of the southern group, are also noted for the vivid hues of the anemones, sponges, shells, and corals covering the bed of the sea, and for the immense number of their fishes.

Notwithstanding their small size, Ternate and Tidor have always been the chief centres of political power in the northern, and Amboyna in the southern Moluccas. These islands have long been occupied by civilised Malays, who easily asserted their supremacy over the surrounding lands, which are inhabited chiefly by rude wild tribes at a low stage of culture. Formerly the Mohammedan sultans of Tidor and Ternate were amongst the most powerful rulers in Malaysia, their dominions stretching westwards to Celebes and eastwards to New Guinea, and comprising all the intermediate islands. It was as heirs to these potentates that the Dutch claimed all the western part of New Guinea, as far as the 141st meridian. In Ternate is still centred most of the trade of the northern Moluccas, which export spices, tortoiseshell, trepang, beeswax, bark, and birds of paradise in considerable quantities. The town of Amboyna (pop. 11,000), capital of all the Dutch possessions in the Moluccas, carries on a flourishing export trade in cloves. Banda is the true home of the nutmeg, which here grows naturally, and arrives at the greatest perfection on the slopes of all the volcanic islands, which are disposed round an inner basin like the fragments of some disrupted crater. Neira or Banda, called also Nassau, occupies the southern extremity of Neira Island on the north side of the basin over against Gunong-Api. Besides the nutmeg and mace, Banda yields sago and coconuts for the export trade, long monopolised by the so-called 'Perkeniers,' descendants of Europeans settled in this group since the beginning of the 17th century, and now perfectly acclimatised. Pop. of Amboyna residency (1920) 622,671; area 182,000 sq. m.

Molybdenum (sym. Mo; atomic number 42, atomic weight, 96; sp. gr. 8.62) is a rare metal, which, in a state of purity, is of a silvery white colour, has a strongly metallic lustre, is brittle, and very difficult of fusion. It never occurs native, and its principal ore is the bisulphide, which much resembles graphite. It is also occasionally found oxidised, in molybdate of lead. The metal may be obtained by roasting the bisulphide in a free current of air, when the sulphur goes off oxidised as sulphurous acid, and the molybdenum is also oxidised into molybdic anhydride (MoO_3), and remains

in the vessel. By the action of charcoal, the reduced metal is then obtained from the anhydride. Molybdenum forms a number of compounds with oxygen. Molybdic anhydride is a white, glistening, crystalline powder, which is sparingly soluble in water, fuses at a red heat to a straw-coloured glass, and unites with bases to form well-marked salts, the molybdates, which are either colourless or yellow. A solution of molybdate of ammonia is one of the most delicate tests for phosphoric acid. Molybdenum forms various compounds with sulphur and chlorine. Molybdenum is used in preparation of steels, also to make a blue pigment for porcelain.

Mombasa, or **MOMBAZ**, the chief seaport and the largest town of the Kenya Protectorate (British East Africa), is situated on a coral island 3 miles long by $2\frac{1}{2}$ broad close to the coast, in $4^{\circ} 4'$ S. lat., about 150 miles N. of Zanzibar. The shores of the island are rocky and abrupt, and the greater part of its surface is covered with dense bush. The only object of historical interest is an extensive fort, built in 1594 by the Portuguese, and restored by them in 1635. Mombasa was visited by Vasco da Gama in 1497; it was then a large and prosperous town (as it was when Ibn-Batûta was there in 1331), with a colony of Christians of St Thomas and Banyans from India. It was held by the Portuguese during the greater part of the period from 1505 to 1698, though not without frequent captures. The native chief put it under British protection in 1823; but, Britain soon abandoning it, it was seized by the sultan of Zanzibar, who in 1888 ceded it provisionally to the Imperial British East Africa Company. They were made definitive masters of the place two years later. See **KENYA**. The chief harbour is one of the largest, safest, and healthiest on the east coast of Africa. See also **KILINDINI**. Mombasa is the terminus of the so-called Uganda railway (opened in 1902). The chief exports are ivory, copra, grain, rubber, and hides. Pop. about 30,000, mostly Africans, with some Arabs and Banyans.

Moment of a dynamical quantity is the importance of that quantity in regard to its dynamical effect relatively to a given point or axis. The most familiar example is the Moment of a Force. For simplicity, take a body movable about a fixed axis—say, a door on its hinges. Everyday experience teaches us that such a door is most easily moved by a push or pull applied as far as possible from the hinge. In moving the door slowly through a certain angle, we must do so much work in, first, causing the necessary acceleration, and then in overcoming the friction of the hinges. If we apply the force at a greater distance from the hinge, it works through a proportionally greater arc, and is therefore proportionately less. Such considerations lead to the definition of the moment of a force about a point as the product of its amount into its perpendicular distance from the point. The tendency of the action of such a force is to cause rotation about an axis perpendicular to the plane passing through the point and containing the force. Thus, in the case of a pendulum, the effectiveness of the force in causing rotation is measured by the moment Wl —where W is the weight of the pendulum, and l is the distance of the line of action of the force W from the centre of rotation C , or (what comes to the same thing) the distance of the centre of mass G from the vertical line through C .

The term moment enters into several other

phrases, all of which relate either directly or indirectly to rotation. Thus, there is the moment of momentum, or angular momentum, whose rate of change is the measure of the moment of the force producing the change. To obtain it for any given body rotating with angular speed ω about an axis, we first imagine the body broken up into a great many small portions of masses m_1, m_2, m_3 , &c. at distances r_1, r_2, r_3 , &c. from the axis, multiply the momentum (mrv) of each mass by its distance, and then take the sum of all these products. The angular speed ω being the same in every expression, the moment of momentum takes the form $\omega (m_1 r_1^2 + m_2 r_2^2 + \text{&c.})$, which it is usual to write in the symbolic form $\omega \Sigma mr^2$. The quantity Σmr^2 , which is the sum of the products of each mass into the square of its distance from the axis, is called the Moment of Inertia about that axis. It is the factor in the moment of momentum, which depends upon the distribution of matter in the body. It enters into all questions of mechanics in which rotation is involved, from the spinning of a top or the action of an engine governor to the stability of a ship. By an obvious extension, the word moment is also used in such combinations as moment of a velocity and moment of an acceleration. Such phrases correspond to nothing truly dynamic, unless we regard velocity as meaning the momentum of unit mass, and acceleration as the rate of change of that momentum. See **DYNAMICS**, **FORCE**, **INERTIA**, **ROTATION**, &c.

MOMENTUM is our modern equivalent of Newton's quantity of motion (*quantitas motus*), which in Definition II. of the *Principia* is stated to be measured by the product of the velocity and the mass. Its dynamic importance is sufficiently discussed under **FORCE**.

MommSEN, **THEODOR**, the most learned historian of Rome, was born the son of a pastor at Garding, in Sleswick, 30th November 1817. He studied at Kiel, next spent three years traversing France and Italy in the study of Roman inscriptions under commission of the Berlin Academy, edited awhile the *Schleswig-Holsteinische Zeitung*, and in the autumn of 1848 was appointed to a chair of Jurisprudence at Leipzig, of which two years later he was deprived for the part he took in politics. In 1852 he was appointed to the chair of Roman Law at Zurich, in 1854 at Breslau, and in 1858 to that of Ancient History at Berlin. Here he was engaged for many years in editing the monumental *Corpus Inscriptionum Latinarum*, projected by the Berlin Academy, and commenced in 1863; and in 1873 he was elected perpetual secretary of the Academy. In 1882 he was tried for slandering Bismarck in an election speech, but was cleared both in the lower court and in that of appeal. His fine library was burned in 1880, whereupon a number of English students presented him with a collection of books to make good at least part of his loss. MommSEN took a share in the work of editing the *Monumenta Germaniæ Historica*, and made his name illustrious by a series of works of vast range and profound erudition. He died 1st November 1903. His greatest work remains his *Römische Geschichte* (3 vols. 1854-56; 8th ed. 1889; Eng. trans. by W. P. Dickson, 4 vols. 1862-67). These three volumes form books i.-v. of MommSEN's plan; vol. v., forming book viii., was issued in 1885 (Eng. trans. by Dickson, *The Provinces of the Roman Empire from Caesar to Diocletian*, 2 vols. 1886). Freeman characterises MommSEN as 'the greatest scholar of our times, well-nigh the greatest scholar of all times . . . language, law, mythology, customs, antiquities, coins, inscriptions, every source of knowledge of every kind—he is master of them all.' But, while admitting readily his wide and sure grasp of

historical sequence, the reader finds Mommsen defective in political and moral insight, and prone to fall down in worship before mere force and success. See *Life* by Bardt (1903).

Other important works of Mommsen's are *Oskische Studien* (1845); *Die Unteritalischen Dialekte* (1850); *Corpus Inscriptionum Neapolitanarum* (1851); his monographs on *Roman Coins* (1850); the edict of Diocletian, *De Pretiis Rerum Venalium* (1851); *Die Rechtsfrage zwischen Cäsar und dem Senat* (1857); *Römische Forschungen* (1864-79); *Res Gestæ Divi Augusti* (1865); *Römisches Staatsrecht* (1871-76; 3d ed. 1887); and his *Digesta Justiniani Augusti* (1866-70).

Mompox, or MOMPOS, a town of north-western Colombia, on the Magdalena, 110 miles SE. of Cartagena. Founded in 1538, it has considerable river-trade. Pop. 15,000.

Monachism, or MONASTICISM (Gr. *monachos*, 'a monk,' from *monos*, 'alone'), may in general be described as a state of religious retirement, more or less complete, accompanied by contemplation, and by various devotional, ascetical, and penitential practices. It is, in truth, Asceticism (q.v.), with the element of religious solitude superadded. The institution of monachism has, under different forms, entered into several religious systems, ancient and modern. That it was known among the Jews before the coming of our Lord appears from the example of the prophet Elijah and from that of the Essenes; and it is probable that religious seclusion formed part of the practice of the Nazarites, at least in the later periods of Jewish history. In the Brahmanical religion it has had a prominent place; and even to the present day the *lamaseries* of Tibet may be said to rival in number and extent the former monasteries of Italy or Spain. The Christian advocates of monachism find in the exhortations to voluntary poverty (Matt. xix. 21) and to celibacy (1 Cor. vii. 37) at once the justification and the origin of the primitive institution. Its first form appears in the practice of asceticism, of which we find frequent mention in the early part of the 2d century. The primitive ascetics, however, lived among the brethren, and it is only in the following century that the peculiar characteristic of monachism begins to appear. The earliest form of Christian monachism is also the most complete—that of the Anchorites or Hermits (q.v.)—and is commonly believed to have in part originated in the persecutions, from which Christians were forced to retire into deserts and solitary places. The hermits maintained from choice, after the cessation of the persecutions, the seclusion to which they had originally resorted as an expedient of security; and a later development of the same principle is found in the still more remarkable psychological phenomenon of the celebrated 'Pillar-saints' (see *STYLITES*). After a time, however, the necessities of the religious life itself—as the attendance at public worship, the participation in the sacraments, the desire for mutual instruction and edification—led to modifications of the degree and of the nature of the solitude. First came the simplest form of common life, which sought to combine the personal seclusion of individuals with the common exercise of all the public duties; an aggregation of separate cells into the same district, called by the name *Laura*, with a common church, in which all assembled for prayer and public worship. From the union of the common life with personal solitude is derived the name *cenobite* (Gr. *koinos bios*, common life), by which this class of monks is distinguished from the strict solitaries, as the hermits, and in which is involved, in addition to the obligations of poverty and chastity which were vowed

by the hermits, a third obligation of obedience to a superior, which, in conjunction with the two former, has ever since been held to constitute the essence of the religious or monastic life. The first origin of the strictly cenobitical or monastic life has been detailed under the name of St Antony (q.v.), who may be regarded as its founder in the East, either by himself or by his disciples. So rapid was its progress that his first disciple, Pachomius (q.v.), lived to find himself the superior of 7000. In the single district of Nitria, the country of the Natron Lakes (q.v.) in the Egyptian delta, there were, according to Sozomen, no fewer than fifty monasteries, and before long the civil authorities judged it expedient to place restrictions on their excessive multiplication. It seems to be admitted that in the East, where asceticism has always been held in high estimation, the example of Christian monasticism had a powerful influence in forwarding the progress of Christianity; although it is also certain that the admiration which it excited occasionally led to its natural consequence among the members, by eliciting a spirit of pride and ostentation, and by provoking sometimes to fanatical excesses of austerity, sometimes to hypocritical simulations of rigour. The abuses which arose, even in the early stages of monachism, are deplored by the very Fathers who are most eloquent in their praises of the institution itself. These abuses prevailed chiefly in a class of monks called *Sarabaitai*, who lived in small communities of three or four, and sometimes led a wandering and irregular life. On the other hand, a most extraordinary picture is drawn by Theodoret of the rigour and mortification practised in some of the greater monasteries. The monks were commonly zealots in religion; and much of the bitterness of the religious controversies of the East was due to that unrestrained zeal; and it may be added that the opinions which led to these controversies originated for the most part among the theologians of the cloisters. An order was called *Acemetæ* (Gr. 'sleepless'), from their maintaining the public services of the church day and night without interruption (see *GREEK CHURCH*).

It was in the cenobitic rather than the eremitic form that monachism was first introduced into the West, at Rome and in Northern Italy by Athanasius, in Africa by St Augustine, and afterwards in Gaul by St Martin of Tours. Here also the institution spread rapidly under the same general forms in which it is found in the Eastern Church; but considerable relaxations were gradually introduced, and it was not until the thorough reformation and, as it may be called, religious revival effected by the celebrated St Benedict (q.v.), in the beginning of the 6th century, that western monachism assumed its peculiar and permanent form. In some of the more isolated churches, as, for instance that of Britain, it would seem that the reformations of St Benedict were not introduced until a late period; and in that church, as well as in the church of Ireland, they were a subject of considerable controversy. One of the most important modifications of monachism in the West regarded the nature of the occupation in which the monks were to be engaged during the times not directly devoted to prayer, meditation, or other spiritual exercises. In the East manual labour formed the chief, if not the sole external occupation prescribed to the monks; it being held as a fundamental principle that for each individual the main business of life was the sanctification of his own soul. In the West, besides the labour of the hands, mental occupation was also prescribed—not, it is true, for all, but for those for whom it was especially calculated. From an early period, therefore, the monasteries of the West, and particularly

those of Ireland or those founded by Irish monks (see COLUMBA, CULDEES), as Iona and Lindisfarne, became schools of learning, and training-houses for the clergy. At a later period most monasteries possessed a *scriptorium*, or writing-room, in which the monks were employed in the transcription of MSS.; and, although a great proportion of the work so done was, as might naturally be expected, in the department of sacred learning, yet it cannot be doubted that it is to the scholars of the cloister we owe the preservation of most of the masterpieces of classic literature which have reached our age.

In the remarkable religious movement which characterised the church of the 12th century (see FRANCISCANS) the principle of monachism underwent a further modification. The *spiritual egoism*, so to speak, of the early monachism, which in some sense limited the work of the cloister to the sanctification of the individual, gave place to the more comprehensive range of spiritual duty, that, in the institute of the various bodies of Friars (q.v.) which that age produced, made the spiritual and even the temporal necessities of one's neighbour, equally with, if not more than, one's own, the object of the work of the cloister. The progress of these various bodies, both in the 12th century and since that age, is detailed under their several titles. The monastic institutes of the West are almost all offshoots or modifications of the Benedictines (q.v.); of these the most remarkable are the Carthusians, Cistercians, Cluniacs, Premonstratensians, and, above all, Maurists. In more modern times other institutes have been founded for the service of the sick, for the education of the poor, and other similar works of mercy, whose members are also classed under the denomination of monks. The most important of these are described under their several heads.

The enclosure within which a community of monks reside is called a Monastery (q.v.), and sometimes convent. By the strict law of the church, called the law of cloister or enclosure, it is forbidden to all except members of the order to enter a monastery; and in almost all the orders this prohibition is rigidly enforced as regards the admission of females to the monasteries of men. To such a length is this carried in the Greek Church that in the celebrated enclosure of Mount Athos not only women, but lower animals of the female sex are rigorously excluded. The first condition of admission to a monastic order is the approval of the superior, after which the candidates remain for a short time as *postulants*. After this preliminary trial, they enter on what is called the *novitiate*, the length of which in different orders varies from one to three years; and at its close they are admitted to the profession, at which the solemn vows are taken. The age for profession has varied at different times and in different orders; the Council of Trent, however, has fixed sixteen as the minimum age. Originally all monks were laymen; but after a time the superiors, and by degrees other more meritorious members, were admitted to holy orders. Amongst the mendicants, those in priest's orders were called 'father,' the lay brothers 'brother' only. In either case, where the order is one of those solemnly approved by the church, the engagement taken at the final profession is life-long and irrevocable.

The name monastery, in its most strict acceptance, is confined to the residences of monks, properly so called, or of nuns of the cognate orders (as the Benedictine), and as such it comprises two great classes, the *Abbey* and the *Priory*. The former name was given only to establishments of the highest rank, governed by an abbot, who was commonly assisted by a prior, sub-prior, and other minor functionaries (see ABBOT). A Priory sup-

posed a less extensive and less numerous community. It was governed by a prior, and was originally, although by no means uniformly (at least in later times), subject to the jurisdiction of an abbey. The distinction of abbey and priory is found equally among the Benedictine nuns. In the military orders the name of Commandery and Preceptory corresponded with those of abbey and priory in the monastic orders. The establishments of the mendicant and, in general, of the modern orders are sometimes, though less properly, called monasteries. Their more characteristic appellation is Friary or Convent, and they are commonly distinguished into Professed Houses (called also Residences), Novitiates, and Colleges or Scholastic Houses. The names of the superiors of such houses differ in the different orders. The common name is Rector, but in some orders the superior is called Guardian (as in the Franciscan), or Master, Major, Father Superior, &c. The houses of females—except in the Benedictine or Cistercian orders—are called indifferently *Convent* and *Nunnery*; their head is styled Mother Superior or Reverend Mother. The monastic institute, from the very earliest time, included women as well as men. The former were called in Greek by the name *nonis* or *nonna*, and in Latin *nonna* (from which the English *Nun*), as also *sancimonialis*. The general characteristics of the monastic institute for females are substantially identical with those of the male orders.

It was to be expected that the monastic foundations in England would not long survive the national rejection of the papal power which was their main support. The monasteries had mostly outlived their days of usefulness, and very inadequately fulfilled the objects of their institution. A general, though not universal decay of religious fervour, and the revelation from time to time of grave scandals within their walls disposed many prudent men to regard them with little favour. But the immediate cause of their downfall was their accumulated wealth with which Cromwell tempted the covetousness of Henry VIII. The dissolution of monasteries was indeed no new idea, for Cardinal Wolsey several years before had obtained bulls from the pope enabling him to suppress certain religious houses and appropriate their funds for other purposes. Henry's proceedings were, however, as unworthy as his motives. He appointed unprincipled agents to visit and report upon the state of all the religious houses in the kingdom. These men performed their work in indecent haste, and upon obviously insufficient evidence brought against the monks generally charges of gross immorality which were embodied in the so-called Black Book, now lost. The king at first acted with considerable craft. He appealed to the selfishness of the greater abbots who had seats in the House of Lords, and silenced their opposition by declaring that in the larger monasteries 'religion was right well kept,' and proposed the confiscation only of the smaller houses (376 in number) with a revenue of less than £200 a year. This ensured the passing of the Act of Suppression in February 1536. But the turn of the 645 greater monasteries soon came. Certain abbots implicated in the rising of the 'Pilgrimage of Grace' were convicted of treason and their houses seized. Then followed another general visitation, and, by bribes, intimidation, and violence, the remaining monastic communities were one by one induced in 1539 to 'surrender' their property to the king. The revenue accruing to the crown by the confiscation is estimated at over £130,000. With this fund six new episcopal sees and certain collegiate churches and grammar-schools were founded, and a few castles built for the defence of the coast. But the greater part of the property fell through purchase or gift into the hands of the nobility and

gentry; and the policy which thus interested powerful laymen in maintaining the new order of things effectually barred the way to the restoration of monasticism in the reactionary reign of Mary. See HENRY VIII.

In some of the German states the temporalities of the suppressed monasteries were retained at the Reformation, and were granted at pleasure by the sovereign, to be enjoyed together with the titular dignity. Some of the German churches, however, in later times, have revived the institution, especially for women (see DEACONESSSES). In England there was the religious community of Little Gidding (1625-47), founded by Nicholas Ferrar (q.v.); Father Ignatius (q.v.) worked for Anglican Benedictinism; in 1865 a sort of Anglican mission order, the Cowley Fathers, was established at Oxford by Richard Meux Benson (q.v.); and others have followed; but here, too, Sisterhoods (q.v.) are far more numerous. In all these Protestant revivals of monachism the engagement is revocable at the will of the individual, as among the Roman Catholic Béguines (q.v.). At the French Revolution the monastic establishments of France were utterly suppressed; and in most of the other Catholic countries of Europe the example has been followed to a greater or less extent. After the Restoration a revival of many of the orders took place in France. The French decree of 1880, breaking up 'unauthorised orders,' dealt with 384 houses with 7444 monks, and 602 houses with 14,003 nuns; there were in all at that date some 25,000 monks and nuns in France. The Associations Laws of the 20th century again required authorisation of houses, and most of the French communities have been expelled or dissolved. In 1835 Spain suppressed 900 monasteries, and most of the rest soon thereafter. Many, however, established themselves illegally, till in 1910 a law forbade the setting up of any more, without consent of the government, pending a new arrangement with the Vatican. Portugal dissolved all its religious houses in 1834. Houses illegally established afterwards were suppressed by the provisional government of 1910. In Belgium and Switzerland monasteries are numerous. In Italy, Sardinia put an end to the monasteries in 1866, and the same measure was extended to the whole kingdom after 1870, the orders being expropriated, and their houses made national property; in all upwards of 2200 houses were suppressed. In 1875 Prussia dissolved all orders save those devoted to sick-nursing (at that date there were in all Germany 2588 monks and 16,846 nuns), but in 1887 readmitted all those orders engaged in pastoral duty, Christian charity, or the contemplative life. In England and Ireland and America, largely as a consequence of suppression elsewhere, monastic institutions have made rapid progress of late years. Most of the orders introduced are active, not contemplative.

The following list gives the name and date of foundation of the chief orders; reference is made to the articles on them throughout this work, and to works cited there; as also to other articles quoted above, to ROMAN CATHOLIC CHURCH, CONGREGATION, &c.; and to Helyot, *Histoire des Ordres Religieux* (8 vols. 1714-21; new ed. 1860); Dugdale, *Monasticon Anglicanum* (new ed. 1817-30); Tanner, *Notitia Monastica* (1744); Möhler, *Geschichte des Mönchthums* (1836); Hill, *English Monasticism* (1867); Milman, *History of Latin Christianity* (1854); Montalembert, *Monks of the West* (Eng. trans. 1861-79);

Harnack, *Das Mönchthum; seine Ideale und seine Geschichte*, 4th ed. 1895; Eng. trans. 1901; Cardinal Gasquet, *English Monastic Life* (1903); H. B. Workman, *The Evolution of the Monastic Ideal* (1913); N. F. Robinson, *Monasticism in the Orthodox Churches* (1916); Coulton, *Five Centuries of Religion* (1923 & seq.). For Buddhist monachism see BUDDHISM, BURMA, CHINA, LAMAISM, LHASA; for Jewish, ESSENES, THERAPEUTÆ. The Serapis religion had also its monachism. St Pachomius is said to have been a monk of Serapis before he was a Christian.

Mon'aco, a small principality on the Mediterranean, 149 miles ENE. of Marseilles, and 9 from Nice. Area, 8 sq. m.; pop. (1873) 5741; (1922) 23,418, of whom 2037 were in the town of Monaco, 10,554 in Condamine, and 10,827 in Monte Carlo.

Monaco.

The territory, which is encircled by the French department of Alpes Maritimes and the sea, consists mainly of the rocky promontory on which the capital is built and a small strip of coast. For more than nine hundred years it has belonged to the family of Grimaldi. Originally of Genoese extraction, they first held lands in France, between Fréjus and Toulon, where the name of the bay of Grimaud still commemorates their sway. They acquired Monaco in 968, Mentone and Roquebrune and Castillon about 1230, and Antibes in 1237. In European politics they sided with the Guelph party. Honoré II. put his country under a French protectorate in 1644. In 1715 the heiress of the Grimaldi of Monaco married Matignon, Comte de Thorigny, and her descendants continued to reign

over their small kingdom. In 1848 Mentone and Roquebrune declared themselves free towns, and in 1860 voted for annexation to France. The prince in 1861 ceded his rights to Napoleon III. for 4,000,000 francs. A constitution was promulgated in 1911. Prince Albert (born in 1848, succeeded 1889, died 1922), a man of science, founded oceanographical and anthropological institutes in Paris, and a great museum (1910) in Monaco. About 1000 of the inhabitants are employed in the rooms and gardens of the celebrated Casino. These gambling-rooms, built at Monte Carlo on ground leased from the Prince of Monaco, belong to a joint-stock company or Société Anonyme. In 1898 the concession was extended to 1947. Large sums go for the upkeep of gardens and houses and management generally; and the company is held bound to defray the municipal expenditure as well. In a single year over 1,000,000 francs has been paid for publicity—i.e. as hush-money—to many newspapers (chiefly Parisian) to suppress hostile criticisms, unpleasant facts, suicides, and the like. The climate of Monaco is milder than that of any other place in the Riviera; palms and aloes grow most luxuriantly.

See Métiévier, *Monaco et ses Princes* (2d ed. 1865); Pemberton, *Monaco Past and Present* (1867); Boyer de Sainte-Suzanne, *La Principauté de Monaco* (1884); Miss Mayne, *Monaco* (1910); and A. Smith, *Monaco and Monte Carlo* (1912).

Monad. See the articles LEIBNIZ, INFUSORIANS.

Monaghan, an inland county of Ulster, in the Irish Free State, lies between Tyrone and Meath; area, 496 sq. m., of which about half is under tillage. Pop. (1841) 200,442; (1881) 102,748; (1911) 71,455 (three-fourths Roman Catholic). The principal towns are Monaghan, Carrickmacross, Clones, and Castle-Blayney. It returns three members to the Dáil Eireann. Monaghan, granted by Henry II. to De Courcey, speedily fell back into the hands of the native chiefs of the sept MacMahon, by whom (with some alternations of re-conquest) it was held till the reign of Elizabeth, when it was erected into a shire. The county possesses two round towers, one, very complete, at Clones, the other at Inniskeen; and there are several raths and Danish forts.

MONAGHAN, the county town, is 76 miles NNW. of Dublin by rail. The town can boast several public buildings of considerable pretensions, among which are the Catholic college and church, the infirmary, and national model school. Population about 4300. See Evelyn P. Shirley's *History of the County of Monaghan* (1877-80).

Monaldeschi. See CHRISTINA.

Monarchy (Gr. *monarchia*, from *monos*, 'alone,' and *archō*, 'I govern;') literally, the government

of a single individual) is that form of government in a community by which one person exercises the sovereign authority; see GOVERNMENT. For Monarchianism, see UNITARIANISM.

Monastery, a class of structures which arose in the middle ages to meet the requirements of the large number of monks that then existed. It is proved by documents that these buildings were

Cistercian Abbey—Model Plan.

at first constructed somewhat after the plan of a Roman house, or rather of a Roman villa or country-house. Records of abbeys as early as the 7th century show that the arrangements were similar then to those of the 12th century. The cloister, which formed the inner court appropriated to the monks, resembles the peristyle of the Roman mansion. The latter was the part of the dwelling communicating with the private apartments of the family, just as the cloister communicated with the refectory, dormitory, and other apartments used by the monks and not entered by the public. There was also in the monasteries, as in the Roman villas, an outer courtyard, in which were situated the various stores, granaries, workshops, and other places required in connection with both these edifices.

There was, however, one entirely new element in the monastery—viz. the church. This was the largest and most important building, and regulated the position of all the rest. The conventual buildings of every abbey in Britain, France, and Germany are so much destroyed that a complete plan cannot be obtained. The annexed plan is a model one made by Mr E. Sharpe, and contains the results of his careful investigation of the Cistercian monasteries throughout Europe (see *Trans. Roy. Inst. of British Architects*, 1871). In northern climates the cloister was usually situated on the south side of the church, for the sake of the sunshine and warmth. It was composed of an open courtyard, square or oblong in shape, surrounded by an open arcade, or covered way. The church formed the north side, and on the east side was situated the chapter-house, with the monks' dormitory over it. The latter was thus in immediate communication with the church, and conveniently placed for the monks' attendance at the services

during the night. The chapter-house in the Cistercian monasteries was usually divided into three compartments by the pillars bearing the arches. The abbot's seat was opposite the entrance door, and a stone seat all round accommodated the monks. The doorway was not closed, and together with an open arch or window on each side of it allowed those in the cloister to hear the discussions in the interior. The sacristy is placed on the north side of the chapter-house, with a door from the church. A similar cell or 'parlour' occupies the south side; then comes a passage or 'slype' leading from the cloister to the gardens, &c. Beyond this is the day-room (miscalled 'fratry') of the monks, a long vaulted apartment running southwards, having a row of columns in the centre and open windows.

The south side of the cloisters generally gave access to the refectory, a large, rather ornamental chamber, usually with an open wooden roof. It was sometimes placed parallel and sometimes at right angles to the cloister. Opposite the door to the refectory and in a vaulted recess stood a fountain or basin where the monks might wash. Adjoining the refectory were the kitchen and offices. The former was frequently a detached building with a large number of hearths, each having a separate chimney in the roof. Along the west side of the cloister, and sometimes extending much farther, lay the hospitium or guest-house, where all travellers were received, and the lay-room above, where they were lodged. A very important room in the monastery was the scriptorium or library, in which the MSS. were written and illuminated; this was situated on the second floor of the chapter-house. The abbot's lodge formed a separate edifice, as also did the infirmary. The whole establishment was surrounded by a wall, and provided with proper gates and defences. The outer gate gave access to the outer court, in which were situated the workshops of the various craftsmen connected with the abbey, and the buildings required in connection with the agricultural employments of the lay brethren.

Such were the arrangements of the Cistercian abbey in the 12th and 13th centuries. In later times the simplicity of the plan was broken in upon. The monks, desirous of more comfortable quarters, divided the dormitory and made it into cells. The open windows were glazed, and even the arches of the cloisters were sometimes enclosed. The early simplicity of the architectural style was also departed from, and the monastic buildings of the 15th century are as rich in decoration as the cathedrals and parish churches. The arrangements of the monasteries of the other orders were, generally speaking, similar to those of the Cistercian, except in the case of the Carthusians. In their convents, where absolute solitude and silence were required, each monk had a small house and garden to himself. These were arranged round the cloisters, which, when the number of monks was large, were greatly extended in dimensions.

See Viollet le Duc, *Dictionnaire et Architecture Monastique*; De Caumont, *Abécédair d'Archéologie*; Dugdale, *Monasticon*; and Mackenzie Walcott's works on the English and Scottish Churches.

Monasticism. See MONACHISM.

Monastir, called also BITOLIA, BITOLJ, a town in Yugoslav Macedonia, in a broad mountain-valley, 136 miles NW. of Salonika by rail (1894). It manufactures carpets and silver filigree, and trades in skins, corn, and agricultural products. Here the Albanian beys were massacred in 1833; it was the scene of terrible atrocities during the troubles in Macedonia (q.v.) in 1902-3. Turkish till 1912-13, it then became Serbian. The Bulgars held it in 1915-16. Pop. 28,000.

Monazite, a rare mineral, a phosphate of

cerium and lanthanum, with some thorium and yttrium, &c., forms brown or yellow monoclinic crystals. It is used as a source of cerium and thorium for incandescent gas-mantles, and is got from monazite sand, which occurs in Brazil and North Carolina, also in India, Canada, South Carolina, and elsewhere.

Monboddo, JAMES BURNETT, LORD, Scottish lawyer and author, was born at Monboddo House, in Fordoun parish, Kincardineshire, in 1714, and was educated at Aberdeen, Edinburgh, and Groningen. In 1737 he was called to the Scottish bar, and soon obtained considerable practice; but the first thing that brought him prominently into notice was his connection with the celebrated Douglas case, in which he acted as counsel for Mr Douglas. In 1764 he became sheriff of Kincardineshire, and in 1767 was raised to the bench by the title of Lord Monboddo. He died in Edinburgh, 26th May 1799. Monboddo's *Origin and Progress of Language* (6 vols. 1773-92) is a very learned, heretical, and eccentric production; yet in the midst of its grotesque crotchets there occasionally flashes out a wonderfully acute observation, that makes one regret the distorted and misapplied talent of the author. Its evolution theory and its assertion of a close relation between man and the orang-utan seems less laughable now; and in his study of man as one of the animals, and of civilisation by the light of savagery, he certainly anticipated the modern science of anthropology. Monboddo published, also anonymously, another work, *Ancient Metaphysics* (6 vols. 1779-99). See Life by Professor Knight (1900).

Monbuttu, a Negro stock in the basin of the Upper Nile and the Upper Welle. See AFRICA.

Moncalieri, a town of Italy, on the Po, 5 miles S. of Turin, with a royal palace (1470), given by the king to the nation in 1919; pop. 15,000.

Monck. See MONK.

Moncontour, a village in the French department of Vienne, situated 48 miles SW. of Tours, saw the defeat of the Huguenots under Coligny by the royal troops on 3d October 1569.

Moncrieff, SIR ALEXANDER (1829-1906), colonel and engineer, born at Edinburgh, was at the siege of Sebastopol, where the silencing of Russian guns suggested the devising of Moncrieff Pits (1868-72). The Moncrieff system of mounting utilises the force of recoil to bring the gun down into the loading position at the bottom of the pit. It is returned into the firing position either, as in the earlier patterns, by a heavy counterweight or by hydropneumatic machinery. In the latter system recoil presses store up the energy of the recoil and enable it to be used to elevate the gun into the firing position.

Moncton, a town and port of entry of New Brunswick, on the Petitcodiac River, 89 miles by rail NE. of St John. It has important railway-shops, and manufactures machinery, iron-castings, woollens, &c. Pop. (1901) 9026; (1921) 17,488.

Mon'dovi, a cathedral city of Italy, 58 miles S. of Turin by rail; pop. 20,000. Here, on 22d April 1796, the Sardinians were totally defeated by Napoleon.

Monera, a class of Protozoa (q.v.) proposed by Haeckel to include the very lowest organisms supposed to be destitute of a nucleus. But this structure has been shown to exist in forms where it was formerly denied.

Monet, CLAUDE, one of the founders of impressionism, was born at Paris 14th November 1840, a Havre merchant's son. Discouraged in his artistic ambitions at home, he was sent in vain on a voyage (like Manet). At Havre he associated with Boudin, and drew caricatures. He served

two years with the Chasseurs d'Afrique, came home with fever, and studied in Gleyre's studio. From 1883 he lived at Giverny (Eure). A landscapist excelling in atmospheric and water effects, he delights in painting the same subject over and over again under changing conditions. He has lived to see violent opposition turned to triumph. See a book by Maclair (trans. 1925).

Money. The term money is used, both in matters of business and in economic theories, in such very different ways that it is impossible to cover them all with a simple definition. Standard coins, bars of bullion which can at once be converted into standard coins, token coins, convertible bank-notes, inconvertible notes, are all included under 'money,' although they present essential differences. In modern societies one of the most important forms of money is 'bank money,' or the money of the money-market, which for the most part consists of neither coin nor notes. The whole of the banking system of the United Kingdom, for example, as well explained in Bagehot's *Lombard Street*, really rests upon the reserve kept by the Bank of England, and every bank receives deposits of 'money,' and makes advances of 'money,' with the use of a very small proportion of coins or bank-notes. A brief survey of the development of the complex monetary system of modern societies from its rudimentary forms will give the best explanation of this uncertainty in the meaning of this familiar word, and also bring out in the clearest way the principal functions of 'money.'

Exchanges first take place by means of barter, but the difficulties of simple barter are obviously very great. A coincidence of mutual wants at the same time and place is the first condition of any exchange, and it is plain that a common *medium of exchange* will obviate one of the principal difficulties of direct barter. If there is some one thing which every one is willing to take, it follows that anything else can be bought or sold against this particular commodity. Accordingly the first function of 'money' is to provide (1) a *medium of exchange*, and its first forms consist of things which are generally desired in simple states of society. Skins, cattle, shells, corn, pieces of cloth, mats, salt, and many other commodities have at different times and places been used as 'money,' in the sense of a common medium of exchange. The commodity chosen, however, will be of little advantage unless it can be used both in large and small quantities. This consideration leads to another primary function of money—viz. (2) as a *measure of value*. Not only is it necessary that things can be exchanged against a common substance, but the rates of exchange must be measured. Finally, as society advances, a basis for (3) *deferred payments*, and also a method of (4) *storing 'values'* without deterioration, become of importance. In order that these four primary functions may be fulfilled, the substance chosen for money must have certain properties, of which the principal are portability or great value in small bulk, durability, sameness of quality, divisibility, stability of value, and cognisability. It was soon discovered that these qualities are possessed in the highest degree by gold and silver. Other metals have been used at different times even for standard money, but all of them fail in one or more of these particulars. Iron is liable to rust, lead is too soft, tin too brittle, and copper too heavy. It may be observed that the importance of the qualities varies according to circumstances. Thus, when, as in modern societies, the greater part of wholesale transactions are effected without the intervention of material money, portability is of comparatively small importance, whilst on the other hand stability of value is of the greatest importance in all kinds of

deferred payments. It is not necessary that all the primary functions of money should be fulfilled by the same thing. In Saxon times, for example, and for long after in England the standard measure of value was the pound-weight of silver, but the actual medium of exchange consisted of silver pennies. At present the actual medium of exchange consists to a great extent of bits of paper—bank-notes, cheques, and various instruments of credit—whilst the standard measure of value is a piece of gold.

So long as the attention is directed to material money, the principal questions that arise are in connection with coinage. At first, after the introduction of the precious metals, it was left to the parties concerned to test their weight and fineness with *caveat emptor* for the rule, and the present unsatisfactory state of the English gold coinage is mainly due to the survival in law of the presumption that it is the duty of the receiver of money to see that it is of full value. But the essential object of coinage is that a responsible authority should affix its stamp to small ingots of metal, in such a way as to signify their weight and purity. Simple and important as this duty appears, history is full of examples of the debasement and deterioration of coins by governments with the view of making a petty gain. It is worth noting, however, that from the earliest times (with the exception of the reign of Henry VIII.) the English silver was kept of the same fineness. It is true that the weight of the coins became gradually less, but it was probably in most cases the recognition of an accomplished fact (through ordinary wear and tear), and was not an attempt to defraud. The evils which arise from the natural or artificial debasement of coins have been well described by Macaulay in his account of the recoinage in the reign of William III. Since the primary object of coinage was simply to furnish a mark of weight and fineness, all metallic money was at first exactly what it professed to be. Thus, the old English silver pound was coined into 240 pennies; and this fact is preserved in the Troy table—20 penny-weights = 1 oz., 12 oz. = 1 pound. In process of time the actual weight of the penny became less than a pennyweight, but the same numbers were still supposed to go to the pound. Finally, a certain amount of gold of a certain fineness was declared to be equal in value to a 'pound of silver,' or rather to 240 pennies. This is historically the answer to Sir Robert Peel's famous question, 'What is a pound?' The technical answer to the question is now given by the Coinage Act of 1870 (in substance the same as that of 1816). The act declares the precise weight of the sovereign in grains, and the proportion of alloy in standard gold. Nominally—until 1914—any one could take standard gold to the mint and get it coined into sovereigns or half-sovereigns free of charge; twenty pounds-weight Troy being coined into 934 sovereigns and one half-sovereign. Practically the time and trouble involved in going direct to the mint induced people to sell their gold in preference to the Bank of England, and at first (within certain narrow limits) the price varied. The bank was compelled to purchase all standard gold at £3, 17s. 9d. per oz., and, as it obtained from the mint £3, 17s. 10½d., there was a small profit by way of brokerage. Allowing for this small difference, it will be seen that the mint price of gold—viz. £3, 17s. 10½d.—simply refers to the number of standard coins made out of a certain amount of standard metal. It follows that this mint price is fixed and invariable so long as the law remains unchanged. Thus, if gold became as plentiful as blackberries, or as scarce as diamonds, the mint price would remain unaffected. At the same time, however, the value

of gold in the sense of its purchasing power over commodities would change according to the variations in the quantity, though the precise nature and extent of the change would depend upon other elements. In some cases government makes a definite charge for coinage—that is to say, practically the weight of the coins returned is so much less than the weight of the bullion brought. This charge is called seigniorage. So long as this charge is paid, however, there is no restriction on the quantity of metal which may be converted into full standard coin.

It is necessary now to notice the distinction between standard money, in the proper usage of the term, and token money. The chief characteristics of the former are that, as just explained, it is coined to an unlimited extent, and further, that for any money contracts it is unlimited legal tender. In 'token' money these two characteristics are absent. The nature and uses of token money are also best explained historically. In the middle ages silver was very scarce, and prices were extremely low. The silver penny was originally about the size of the present threepenny-piece; consequently for the low range of prices then current it was inconveniently large and valuable. In a petition of the date of 1330 it was pointed out that 'beer is one penny for three gallons,' and that a penny is the smallest coin, and the petitioners pray that smaller coins may be struck to pay for their little purchases, and 'for works of charity.' The great practical difficulty, however, was to make very small coins of full standard value. So much was the need of small change felt, however, that by the time of Elizabeth the people had resorted largely to 'tokens' of lead, tin, and even leather. These 'tokens' were at first private issues, and practically were like very small promissory-notes. It was soon found that they were forced into circulation by unfair means, and then the issuers refused to change them for goods or sterling money. The remedy adopted in 1613 was to give a monopoly of striking copper or brass farthings to certain persons for a consideration. This privilege, however, was so much abused, that in many parts of the country, including London, there was hardly any gold or silver left—the whole circulation being brass farthings. The patentees tried to force these farthings on the American colonies, but it is recorded of Massachusetts—March 4, 1634, at the General Court at New Town, brass farthings were forbidden, and bullets were made to pass for farthings. These 'royal' tokens were no sooner suppressed, owing to the abuses which they had caused, than they were again replaced by private tokens, and it is said that over 20,000 different kinds were in use between 1648 and 1672. Evelyn in his *Diary* speaks of the tokens issued by every tavern, 'passable through the neighbourhood, though seldom reaching farther than the next street or two.'

From this slight historical sketch the principles which should regulate the issues of 'token' money stand out clearly. The smallest coins cannot be made of the precious metals of full value—e.g. a silver farthing would be less than one-tenth of the present threepenny-piece—and, accordingly, baser material must be used. Here, however, the danger arises of going to the other extreme and making the coins too large. But this is only a minor difficulty compared with the necessary condition that the token coins must bear a fixed relation to the standard coins in value. Thus we arrive at the fundamental principles of 'token' coins; they should be issued in limited quantities, be legal tender to a limited extent, and their so-called intrinsic value should be less than the

nominal value. Even those nations which use both gold and silver as standard money (see BR-METALLISM) are compelled to use token coins for small values, whilst nations which have a gold standard must make all their silver coins 'tokens.' With the progress of civilisation 'representative' money, as it has happily been styled by Jevons, became of more and more importance. The Romans, for example, had a highly-developed banking system, which, however, was broken up on the disruption of the empire. In the early mediæval period bills of exchange were used for foreign payments; and that they were considered as 'representative money' is shown by the fact that in England, up to the Tudor period, their value was regulated by the Royal Exchanger, a high official connected with the mint. The development of banking in the modern sense was very slow. The earliest banks in Italy were finance companies which provided governments with loans, but the great banks of the north of Europe were expressly designed to provide good money to meet the payment of bills of exchange (see Adam Smith's account of the origin of the Bank of Amsterdam, *Wealth of Nations*, book iv.). The money in the great trading centres was drawn from various countries, and was in general debased and worn. The banks took this bad money from the merchants and gave them good bank money in return. The merchants, however, allowed the money to remain in the bank, and handed one another transfers. It was soon discovered that a small amount of actual coin was sufficient to meet all liabilities, and, accordingly, the remainder was lent. In this manner 'bank money' has in process of time come to consist of a large mass of representative money supported on a metallic basis. See BANKING.

It remains to notice briefly the changes in the monetary system herein described which were introduced in the war period. In 1914 the gold standard (the sovereign) was virtually abandoned, and paper money (the Treasury note), which had no gold basis, was issued by government, with unsatisfactory results. In 1918 the Cunliffe Commission advised a gradual return to the pre-war system. This recommendation is partially given effect to in the Gold Standard Act, 1925.

Compare, on the difficulty of defining 'money,' Sidgwick's *Principles of Political Economy*, book ii. chap. iv.; on the history of material money, Ruding's *Annals of the Coinage*, Dana Horton's *Silver Pound*, Kenyon's *Gold Coins of England*, Hawkins's *Silver Coins of England*; on tokens, Boyne's *Tokens in the Seventeenth Century*; on the 'money market,' Bagehot's *Lombard Street*; on the general principles, Jevons's *Money*, Professor F. A. Walker's *Money*, Professor Nicholson's *Money and Monetary Problems*, Hartley Withers's *Meaning of Money* (1909). Money-wort, a name given to various plants—*Dioscorea*, *Lysimachia*, *Thymus*, &c.

Monge, GASPARD, a French mathematician and physicist, was born of humble parentage at Beaune, in the department of Côte d'Or, 10th May 1746. At fifteen he went to study natural philosophy at the Oratorian College of Lyons, and afterwards obtained admission into the famous artillery school at Mézières, where he invented the method known as 'Descriptive Geometry.' In 1780 he was chosen a member of the French Academy, and was called to the Paris Lyceum as professor of Hydrodynamics. During the heat of the Revolution he became minister of Marine, but soon took charge of the great manufactories for supplying republican France with arms and gun-

powder. After he had founded the École Polytechnique, he was sent by the Directory to Italy. There he formed a close friendship with Bonaparte, and, following him to Egypt, undertook the management of the newly-founded Egyptian Institute. On his return to France he resumed his functions as professor in the École Polytechnique, and, though his reverence for Napoleon continued unabated, he hotly opposed his aristocratic and dynastic views. The title of Count of Pelusium was conferred on him by Napoleon. He died 28th July 1818. His principal works were *Traité Élémentaire de Statique* (1788), *Leçons de Géométrie Descriptive* (1795), and *Application de l'Analyse à la Géométrie* (1795).

Monghyr, a picturesque city of Bihar, in India, on the right bank of the Ganges, 80 miles E. by S. of Patna, consists of the fort, a rocky crag projecting into the river, and the native quarters. From the 12th century onwards it was a place of considerable strength; in the 18th century Mir Kasim made it his headquarters. He established an arsenal, and its armourers are still famed. Pop. (1891) 57,077; (1921) 46,825.—The district has an area of 3927 sq. m.; pop. 2,029,000.

Mongol. See IDIOCY.

Mongolia. This word is rather a European geographical name than Chinese or Mongol, which last term, though of ancient origin (see MONGOLS), had no mediæval existence until Genghis Khan adopted it to distinguish the particular sub-tribe of *T'atan* or *T'a-t'a* to which he belonged: he never conceived the idea of Mongolia as an area. In Hiung-nu (Hun) times, 2000 years ago, in indicating the same area, the Chinese spoke of 'North of the Desert' (Urga region), 'South of the Desert' (Great Wall region), and 'Celestial Mountains North' (road to Harashar, Ili, &c.), and these terms have endured throughout Turkish times to this day. Both the first great Hun conqueror (200 B.C.) and the great Turk conqueror (500 A.D.) distinctly conceived the idea of Hun 'empire' and Turk 'empire'; but this expression referred to the ever-shifting tribal units subordinate to Hun and Turk rule, rather than to the elusive territory over which those units wandered, and for which they fought off and on: as the Chinese aptly put it, 'their country is the back of a horse'—it was an ever-moving ocean of riders rather than fixed settlements of cultivators. When, after over a century of imperial rule from what we now call Peking, the millennium-later Mongols were driven helter-skelter beyond the Great Wall, the Chinese of the succeeding Ming dynasty (1368–1644) spoke of them, and officially record them in history, by their old name *T'a-t'a*. At first they only knew of the Genghiside or eastern groups; and when later on they began to hear of the rival westerners, they called them Elut-ê (Eleuths) or 'Allies,' who gradually developed a 'Kalmuck' empire of their own, under a supreme chief whose title was *K'un-t'ai-chai* or 'chief *dai'dji*' (the 'Kontaysha,' so graphically described by John Bell of Antermony two centuries ago). These eastern and western *T'a-t'a*, or Mongols, fought with each other and with China throughout the Ming dynasty, the western chief Essen even capturing a Chinese emperor (1450) and detaining him for some years. For more than a century after this the Chinese lost all touch with the Eleuth or Kalmuck empire. Meanwhile the Manchu power was developing, and the divided, undisciplined, and exhausted eastern Mongols found it to their interest to abandon Ming disorganisation and support Manchu ambitions; the result was the fall of the now thoroughly corrupt and effete Ming dynasty, and a family alliance on equal social

terms between princes of the eastern Mongols and ruling Manchus, which has been prudently continued under the Chinese republic 'of five races.' The Manchus had a century of hard fighting before the western Mongols were reduced to obedience, part of them—the Turgut branch—migrating to Russia, whither in 1712 the Manchu emperor K'ang-hi sent an envoy named Tulishen to try and coax them back from their settlements between the Volga and the Yaik, where their Khan Ayuki was actually visited by Peter the Great in 1722: there were then about 100,000 tents of them. It was not, however, until the brilliant Manchu emperor K'ien-lung had made a clean sweep of the Eleuths or Kalmucks of Ili (1757–58) that the Turgut Eleuths in Russia, disgusted with Catherine's attempt to enlist them for service in her European wars, decided to return in a body to the Ili region, where a miserable remnant of them, numbering 70,000, arrived about 1760: they were received with great kindness, and have remained there ever since.

Mongolia, taken in its popular sense as it appears on modern maps, seems to be an arid tableland, surrounded on all sides by more or less wooded and fertile districts, and intersected by several formidable mountain chains, whose watersheds, however, are only fructifying on the outward faces. As early as 984 B.C. the Emperor Muh, of a dynasty tintured with Tatar colourings in its origins, journeyed over a portion of this desert, including that part, often mentioned in Chinese histories, where millions of birds used to congregate annually for moulting purposes; but it is only after the accession of the unmistakably pure Chinese Han dynasty (200 B.C.) that specific mention is made of the *Moh* (defined by the dictionaries as 'sandy surface'), or *sha-moh*, 'sandy Moh.' The alleged Mongol word *Gobi* is mentioned in one fragment of a long-extinct unofficial Chinese history published about 250 A.D.; but this was long centuries before the word 'Mongol' appeared in any disguise: the 'windy Ko-pih' in question was on the Hami-Turfan road, and may well be some form of Turkish. The mountains and forests, with the fertile tracts which practically surround this inhospitable plateau, of course produce refreshing watersheds, forming river-systems running, as above indicated, northwards towards Siberia, eastwards towards Manchuria, and westwards towards Russian Turkestan; there are none of any bulk, except perhaps the Etzina, running northwards towards the Desert from China, and that perhaps explains how it was and ever has been easy for troops of hardy horsemen, whether Huns, Turks, or Mongols, to swoop upon the half-Chinese settled communities, always tentatively advancing northwards, and, if successful, to carry off booty in the shape of grain, spirits, girls, silks, flosses for wadding, and young men to train up as cavalry or servants. The town of Etzina (mentioned by Marco Polo) was invaded by Genghis in 1226, and seems to be identical with the Kara-Khoto, where Kozloff in 1908 discovered literary treasures. It is not easy to describe in detail this vast Mongolian area of 1,400,000 square miles, which within its four present boundaries has probably never maintained a population of more than 3,000,000: in 180 B.C. the Chinese were told at Hiung-nu headquarters that the whole population did not exceed that of one large Chinese city. These present boundaries are Siberia to the north, of which the Chinese knew and record almost nothing until their attention was drawn more closely to the movements of the Russians in 1858. True, Ivan the Terrible's vague missions of 1567, and Mendez Pinto, the Portuguese adventurer's equally vague explanations of about that date, must have

suggested something of an important region north of the T'a-t'a, even to the already unenterprising Ming dynasty (1368-1644), but nothing is officially recorded. The boundary to the south is now what it has always been since 200 B.C.—i.e. the line of the Great Wall and its extensions. To the west the boundary has always been a shifting one, accordingly as fierce horsemen of 'Mongolia,' whether Huns, Turks, or Mongols, modified by their temporary conquests the political status of what successive Chinese histories have termed the *Si-yü* or 'Western Regions.' To the east the boundary has, again, always been what it is now—that is to say, Manchuria and Korea; always with the reserve, however, that these two nations have themselves shifted ground very much, and that the no-man's-land which in 200 B.C. separated the Hiung-nu horsemen from the pig-breeding Tunguses was, nearly three centuries ago, allotted by the victorious Manchus to friendly Mongols. Accordingly as the successive Chinese dynasties recovered breath and proved vigorous enough to advance westward and form 'turning' alliances, so were the predatory horsemen gradually driven north-westwards, until at last they threatened mid-Europe, and actually reigned as the 'Golden Horde' for several centuries in Russia. It was only by the remarkable political sagacity of the Manchus in first of all granting titular conditions compatible with self-respect, and then unmaning their spirit and keeping down the popular increase by encouraging lamaism and celibacy, that at last they succeeded in taming this secular or progressive link between Far East and Far West. The Great Desert has numerous lakes, which partly or entirely dry up according to season; there are also many elusive 'sand rivers' and genuine oases, which enable the restless denizens to find their way across at all times; the grassy steppes of the easternmost portion are especially refreshing to look at in the spring: this part is what the Chinese call the *ts'ao-ti* or 'grass-land,' now occupied by the Inner Mongols. The mountains of Mongolia range from the Süeh Shan and the Altai in the west to the Peh Shan or White Mountains of Hami and the Alashan north of the Great Yellow River Bend; then eastwards past the Yin Shan, K'i-lien (= Heaven) Shan, Nan Shan; and finally the famous triple Hing-an system, roughly dividing Mongolia from Manchuria. Chinese historians apply all these terms very loosely, and the confusion to the casual reader is further confounded by the irregular use of Mongol or Turkish equivalents, such as Bogdo-ula, Ong-ku, Tengri-dagh, Ak-tagh, &c., which are in any case, even when the respective positions are clearly indicated, only satisfactorily understood by specialists. Any attempt to describe and define topography is futile without a clear map, and, given a clear map, laboured description is unnecessary. North and south of the Desert there are fine forests and pasture tracts, but in the *sha-moh* or *Gobi* itself there are only found at distant intervals a few dwarf or stunted willows, elms, mugworts, with occasional patches of struggling grass. Hence it is clear that horsemanship was always indispensable to get from one desirable point to the other, whether for purposes of war, hunting, or mere casual distraction. It is curious that the Chinese princes, who used three-horse chariots (in form not unlike the Egyptian and Assyrian) in their wars against each other, never seem to have acquired the art of mounted horsemanship until they found they were, in their steady advance north from the Yellow River, liable to Tatar surprises at great disadvantage. Accordingly, about 300 B.C. we find one of the most powerful Chinese feudal kings (North Shan Si) deliberately adopting Tatar costume at

his court so as to facilitate military operations on horseback; yet even a century after this, when the Hiung-nu Khan Baghdur surrounded the founder of the Han dynasty with half a million horsemen, we are told that the Chinese had perforce to submit to shameful terms of peace because their army of 400,000 men consisted entirely of infantry. The accounts of early Babylonia and early Egypt seem to show clearly that the introduction of the horse into those regions for warlike purposes was comparatively recent, probably by way of Elam and Syria; and thus, in one sense, the Scythian horsemen may indirectly and unconsciously have been the earliest effective link between Far East and Far West, for there does not appear to be any other instance in the world's history of self-supporting mounts careering fearlessly over thousands of miles in search of adventure, carrying all indispensable things with them, and as often as not accompanied by their women and children.

When the petty tribe of Manchus (about 1560) became conscious of its own relationship with the kindred tribes, and linguistically also with the Kitans and Nüchiens who had preceded the Mongols as emperors of North China, it proceeded methodically to organise itself, by means of understandings with certain Mongols and with China, in such a way that when at last Peking fell helplessly into Manchu clutches, it could safely set about securing its Mongol rear before marching upon its South China front. As stated in official Manchu history, 'the Mongols may be divided into four grand categories: (1) the Inner Mongols, south of the Desert; (2) the Outer Mongols, north of the Desert; (3) the Eleuths, west of the Desert; and (4) the Mongols of Kokonor.' The Inner Mongols practically continue the organisation into Six 'Ten Thousands' of the Genghis-Kublai times, except that, under the Manchus, these *Tumans* or 'Ten Thousands' have always been termed the Six *Mêng* or Leagues, embracing between them twenty-four tribes of forty-nine flags, one to three flags a tribe, only two leagues of the six having so many as six or seven flags to one tribe. Until the republic slightly modified the Chinese control, which in military matters lay with two generals at Kalgan and Jêhol respectively, in civil matters with the viceroy of Chih Li province, the so-called Mongolian Superintendency at Peking (*Li-fan-yüan*, or department for managing protected states, which also dealt with Tibet and lamaism generally), reserved to itself questions of rank and succession; but now there is a 'Mongol-Tibet Court' (*Mêng-Tsang Yüan*), which from 1912 to 1922 was under the competent and faithful direction of Prince Kungshang Norbo of the Kartsin Flag (direct descendants of Genghis Khan); however, in 1922 his second in command seems to have successfully intrigued him out of power. Meanwhile three new 'places'—akin to, but not actually regulation provinces—have been created at Jêhol, Kalgan, and Kwei-hwa Ch'êng (the site of Marco Polo's Tenduc), charged with the mixed administration of mixed Mongol-Chinese affairs. Administrative confusion, corruption, and incompetency is such all over China that it is not easy precisely to define any governmental arrangements. A healthy instinct, however, teaches the corrupt provincial governments of Tibet, Kokonor (Mongols, Tibetans, Mussulmans), and Kan Suh, as well as the highly honourable and competent government of Shan Si, that these non-Chinese or mixed peoples must be treated fairly, and the organisation of a new province called Kan-pien will bring all these races into more harmonious touch with one another. The Outer Mongols, north and west of the Desert, were not subdued

by the Manchus until long after the friendly incorporation of the eastern Mongols just described. Those north of the Desert have been called Kalkhas ever since the accession of the Manchu dynasty. There are four great tribes or divisions of them, each under a native *han* or khan, in many respects ruling independently. The lamaist dignitary, who under the Ming dynasty had settled at Kwei-hwa Ch'eng, south of the Desert, finally fixed his residence at Urga, north of the Desert; both these places were once Hiung-nu and Turkish capitals, so that in a certain way the Kalkhas are carrying on old traditions. The last lama dignitary died in May 1924, and at present the rivalries of Soviet Russia, 'White' Russia, and certain Chinese military cliques have led to various wars and confusions in and around Urga, so that there is some prospect of China's coming into her own again. Previous to the republic the western Kalkhas were to a certain extent under the control of a Manchu pro-consul at Uliasutai, whilst the eastern were more or less influenced by a similar official at Urga.

The Eleuths or Mongols west of the Desert were not entirely subdued until the Manchu dynasty had occupied the Chinese throne for a century, during which century the Eleuths had had a certain 'milk-kine' control over the Perso-Turki populations of the Tarim valley. An attempt was made by Yakub Bey towards the end of the 19th century to establish a new empire over the Kashgar, Ili, and Harashar regions, but this ambitious effort was thwarted by an exceptionally capable general in the employ of the Manchu government, and by 1881 both Sungaria (Eleuths) and Kashgaria (Tajiks) were firmly established as 'New Province.'

In the year 1890 Professor Heikel of Helsingfors University discovered near a *tsaidam* or marsh in the Orkhon valley a remarkable stone slab dated 731 A.D., with inscriptions in Chinese and in an unknown and then indecipherable language, since discovered to be early Turkish. Quite an extensive literature in Finnish, Swedish, Danish, Russian, German, French, &c., has since grown up in connection with this question. Suffice it to say here that the site of the stone slab was the headquarters or capital of the then ever-shifting and restless Turks; just as, a thousand years before that, it had been the 'north of the Desert' encampment of the Hiung-nu or (presumably) Huns. Moreover, the terms used in the Chinese emperor's lament over a distinguished Turk warrior prove clearly that the Turks had directly inherited the more ancient organisation, and even titles, of the Hiung-nu. Farther west, a number of Ouigour and other Turkish monumental inscriptions have since been discovered and deciphered. This is not the place to enlarge upon a purely scientific subject, having only indirect reference to Mongolia; but the fact that some one had 1200 years ago adapted a form of Aramean script to the (then) Turkish language, and that Aramean itself—as indeed every form of European alphabet—was most probably based upon the earliest alphabet of all—the Phœnician—creates another secular link between Far East and Far West.

Mongols, an Asiatic people belonging to what is commonly called the Ural-Altaic branch of the human family, are said (on somewhat doubtful authority) to derive their name from a word *mong*, which means 'brave,' 'bold.' Their origin and early history are lost in a dim antiquity. Chinese annals first speak of them as dwelling (6th to 9th century) in what is now Mongolia north of the desert of Gobi, and in the regions well to the south-east of Lake Baikal. The origin of the royal house is enshrouded in myths, the maternal

ancestor being by tradition a she-wolf; possibly (it has been suggested) the house was descended from a ruling family of the Turks (Hiung-nu); but the cradle of the Mongol people seems to have been on the plains between the river Onon, the Orkhon, and the Kerulon, the latter a tributary of the Argun, and this was at least a century before the word *Turk* came into use. The Old and New T'ang dynasty histories speak of the Mung-uh or Mung-wa as being the southernmost of five tribes grouped under the name Shih-wei, and about 550 A.D., when the Turkish conquests began, the Turks sent three military officers of *tudun* rank to govern these Shih-wei. It was in that region that Genghis Khan was born, and in that region that he fixed his permanent camp or capital, at a place called Karakorum (in Chinese Ho-lin). An ancestor of the great conqueror ruled in the middle of the 12th century over a confederation of Mongol tribes powerful enough to be a serious menace to the Nüchên or Kin empire of North China; and at the same time he was able to carry on a bitter contest against the other neighbouring Tatars. That the confederation was loose—probably the only tie was the compelling will of the energetic chieftain—is indicated by Temujin's (i.e. Genghis Khan's) early struggles. It was only by dint of hard fighting and tenacious persistence that he was able to maintain undiminished the power possessed by his father, and his father's father before him. But the conqueror's genius was in him, and he died supreme monarch of all central Asia (see GENGHIS KHAN). By his will his conquests and territories were divided amongst his sons; the third, Ogotai, succeeded him in 1229 as khakan or chief khan of all the Mongol people. Batu and Orda, the sons of the eldest son (Juchi), were invested with Khwarezm, the region watered by the rivers Ural, Oxus, and Jaxartes; Jagatai, the second son, received the territories between Bokhara; the Irish, and the Gobi; the region between the Irish and Lake Baikal was assigned to Ogotai; and to the youngest son, Tuli, was given the home country south of the Baikal. The first care of Ogotai was to complete, in conjunction with his brother Tuli, the conquest of North China. The capital of the Nüchên or Kins was taken in 1234, and, the last emperor of the dynasty having hanged himself, the Mongol ruler became emperor in his stead. North China having been thus subdued, Ogotai proceeded to conquer China south of the Yellow River, then governed by the Sung (Marco Polo's Manzi) dynasty, and to reduce Korea. Meanwhile another army, commanded by Batu, attacked and subdued the principalities of what is now Russia—Bulgaria on the Volga, Riazan, Moscow, Vladimir, Kieff. The force then divided: one division under Batu entered Hungary, crushed the Hungarians on the river Sayo, an affluent of the Theiss, and captured Pesth and Gran (1241); the other division overwhelmed the Poles and their German allies near Liegnitz; after some delay, they pushed on into Moravia. During the same period yet another Mongol army was assailing Khwarezm, which the son of the former ruler had recovered. This army drove Jelal-ud-Din out of his kingdom, overran Azerbaijan, and in 1236 Armenia and Georgia, in all of which campaigns their path was marked by terrible cruelties and atrocities. Ogotai died in 1241. Kuyuk, his son and successor, reigned seven years, and he was followed by his cousin Mangu, a son of Tuli. Both princes favoured Christianity. During Mangu's reign his brother Hulagu won great fame as the punisher of the Assassins (Ismaelites) in Persia, and as the destroyer of the khalifate of Bagdad. Moreover, he subjugated Syria, captured Aleppo and Damascus, and threatened Jerusalem. In-

vested with these countries, he founded the kingdom of the Ilkhans in Persia (q.v.). Mangu's successor was his illustrious brother Kublai (q.v.) Khan, whose descendants ruled over China (q.v.) from 1294 to 1368. This eastern division of the Mongols (the T'a-t'a of Chinese history, 1368-1644) finally was expelled from China, and its power crushed by the Chinese, in the end of the 14th century. It was reserved for the Manchus to crush the western division or Eleuths in the 18th century; they have uniformly used the term *Mengku* or Mongols for the northern and eastern groups since 1644. The same Manchu rulers gradually absorbed the various small bodies of Mongols scattered over the centre of Asia, from the Great Wall to the Altai Mountains on the west and Tibet on the south-west. Of other Tatar tribes which had formed part of the Mongol empires, in the west of Asia and the east of Europe were formed the Kipchak (q.v.) states—in Russia, the Golden Horde, which subsequently broke up into the Tatar (q.v.) khanates of Kazan, Astrakhan, and the Crimea; in Turkestan, the Uzbek (q.v.) principality, out of which grew the khanates of Bokhara and Samarkand. Towards the end of the 14th century Toktamish made himself chief of the eastern Kipchaks, and united thereto the chieftainship of the Golden Horde; but in 1395 his power was crushed by the greater Tamerlane (q.v.). In 1519 Baber (q.v.), a descendant of Genghis' son Jagatai, founded the Mogul empire in India. The Kalmucks (q.v.) or Eleuths (as we have just seen) also belong to the western branch of the Mongols.

The total number of Mongols now under Chinese rule is loosely estimated at two millions. They live for the most part in the immense plateau of central Asia called Mongolia (area, 1,288,000 sq. m.), which is girdled on all sides by lofty mountain chains (Altai, T'ien-Shan, Hing-an, &c.). Its southern portion consists of the vast desert of Gobi. These people are still nomads, as their historic ancestors before them always were. Their wealth consists in flocks of sheep, herds of horses (small, but very enduring), cattle, camels, and goats. They are mostly Buddhists, though those in the west are in part followers of Shamanism, as most Turanians or Tatars were before the days of the great Mongol conqueror. As a rule they are hospitable, though indifferent to personal comfort, addicted to cattle-stealing and to drink, but when sober good-hearted and friendly; on the whole, life being easy and their wants few and simple, they display a lack of foresight, and are lazy and dirty. They dwell in strong circular felt tents, which are their only protection against the violent sandstorms of summer and the still more terrible snow-hurricanes of winter. They are fond of making religious pilgrimages to Urga (q.v.), the religious capital of the country, and to various other shrines in China and Mongolia. Kalgan and Kiachta are the principal commercial centres; but what with the Russian political interference before the Great War, coupled with the Soviet complications, both commerce and policy have been unsettled. It is difficult to estimate the numbers of the western Mongols, as they have in many parts commingled with their Turkic neighbours; but see such articles as Kipchaks, Kirghiz, Russia, Siberia, Tatars, Turkestan, &c. See also **TURKS, ASIA**. The Buriats (q.v.), almost entirely subject to Russia, are a branch of the Mongol race.

The term Mongolic is used by ethnologists to describe the group of cognate languages which constitute one division of the Turanian (q.v.) family of speech. What Mongol literature there is consists for the most part of translations of religious works from Tibetan and Chinese, historical works (notably the chronicles of the Lama Ssanang

Setsen in the middle of the 17th century), of folk and fairy tales, and a few poetic productions. Perhaps the best known of the folk-tales are the collection entitled *Siddhi-Kâr* (ed. Jülg, 1868). Others have been published by him (1866-69), by Bergmann (1804-5), I. J. Schmidt (1839), and Russian savants.

See Howorth, *History of the Mongols* (1876-88); Gil-mour, *Among the Mongols* (1888), *More about Mongolia*, *More about the Mongols* (1893), and his *Diaries* (ed. Lovett, 1892); Parker, 'Mongolia after the Genghizides and before the Manchus,' in *R.A.S. Journal* (North China Branch), 1913.

Mongoose. See **ICHNEUMON**.

Monica. See **AUGUSTINE**.

Monier-Williams. See **WILLIAMS**.

Monism, a philosophical theory that all being may ultimately be referred to one category. Thus idealism, pantheism, materialism are monisms, as opposed to the Dualism (q.v.) of matter and spirit. See **PHILOSOPHY**, **HAECKEL**.

Moniteur, **LE**, a French journal, started by the publisher Panckoucke, 5th May 1789, under the title of the *Gazette Nationale, ou le Moniteur Universel*. During the Revolution its reports, &c., were of very great importance, and its value was immensely increased when, in 1800, it was made the official organ of the government. It retained the privilege (without the first title, *Gazette Nationale*, which was dropped in 1811) down to 1869, when it was supplanted by the *Journal Officiel*. Afterwards it was issued as an Orleanist or private Conservative paper.

Monitor, a name given to a genus of Lizards somewhat isolated from other lizards in structural characters. They are the largest of existing lizards; a specimen acquired by the College of Surgeons in London measured 6 feet 10 inches. The tail of the greater number is laterally compressed, the better to adapt them to aquatic habits. They have received the name Monitor from a notion, due originally to a confusion between the Arabic name *Varan* and the German word *Warnung*, that they give warning by a hissing sound of the approach of a crocodile or alligator. There is only one genus, with many species.—The Monitor or *Varan* of the

Monitor (*Varanus niloticus*).

Nile (*Varanus niloticus*) is of a rather slender form, and has a long tail. It is olive-gray, mottled with black. It attains a length of five or six feet. Crocodiles' eggs or young crocodiles form the chief part of its food. It is a curious superstition in India that the young of the monitor is more deadly than the most venomous serpent.

Monitor. See **NAVY**.

Monitorial System, employed by Dr Andrew Bell (q.v.), when superintendent of the Orphan Hos-

pital, Madras, in 1795, and by Joseph Lancaster, makes use of the more advanced boys in the school to instruct the younger pupils. See EDUCATION (*England*). The monitorial system is not, as is commonly supposed, a method of teaching; it is simply a method of organising schools, and of providing the necessary teaching power. At a time when the whole question of primary education was in its infancy, the state refusing to promote it on the ground that it was dangerous to society, and the public little disposed to contribute towards its extension, it was of great importance that a system should be adopted which recommended itself as at once effectual and economical. But its value as an educational agency was universally overrated, and in the end it broke down.

Monk. See MONACHISM.

Monk, GEORGE, Duke of Albemarle, soldier of fortune and restorer of the English monarchy, was the second son of Sir Thomas Monk of Potheridge, near Torrington, North Devon, and was born either there or at Lancross on 8th December 1608. He saw service first in the expeditions to Cadiz and Rochelle (1625-27), and then for nine years in Holland, returning to England in 1639, in time to take part in the two Bishops' Wars with the Scots. In 1642-43 he commanded a regiment against the Irish rebels, in 1644 was taken prisoner at Nantwich by Fairfax. He lay two years in the Tower, where he solaced himself with frail, ugly Nan Ratsford or Clarges (his future duchess), and whence he freed himself by taking the Covenant—Clarendon hints that he did so for money. As major-general in Ulster he so commended himself to Cromwell, still more by his brilliant conduct at Dunbar (1650), that next year he was left to complete the subjection of Scotland. In 1653 he was associated with Blake and Deane in naval operations against the Dutch, and won two great sea-fights over Tromp (q.v.); in 1654 Cromwell sent him back to Scotland as governor, in which difficult office he acquitted himself with vigour, moderation, and equity. Even the Highlands were reduced to order. His home for five years was Dalkeith, where he 'was ever engaged in business or in planting, which he loved as an amusement and occupation.' After Cromwell's death, seeing everything in confusion, and a splendid chance open to him who dared seize it, on New-year's Day 1660 he crossed the Border with 6000 men, and five weeks later entered London unopposed. So far he had kept his intentions profoundly secret. Still every one felt that the decision lay with 'Old George'; every party courted him; the Republicans even offered him the protectorate. But, while he offended nobody, he declined to connect himself with any of the sectaries, and waited patiently the course of events. From the first, his own wish, dictated by no high motive, had been to bring back the Stuarts; and before long he saw that the nation at large was with him. The freeing of the Rump parliament from the army, the re-admission of the excluded members, and the election of a new parliament—these were his wary steps towards the Restoration; on 23d May he welcomed Charles II. on the beach at Dover. Monk now was made Duke of Albemarle, and entrusted with the highest offices in the state. But he soon retired from political affairs. In 1665, when the plague ravaged London, and every one fled that could, as governor of the City he stuck bravely to his post, and did his best to allay the panic and confusion. Next year he was employed as second in command of the fleet sent under the Duke of York against the Dutch, and was defeated by De Ruyter in a sea-fight off Dunkirk, but soon after gained a bloody victory over him off the North

Foreland. He died on 3d January 1670, and was buried in Westminster Abbey.

See, besides works cited at CHARLES I., CROMWELL, and CHARLES II., the *Lives of Monk*—or *Monck*—by Gumble (1671), Skinner (1723), Guizot (trans. 1851), Corbett (1889), and E. F. Ward (1915); Gardiner's *Civil War* (1865-1903); Firth's *Last Years of the Protectorate* (1910); and the notes and introduction to an *Address from the Gentry of Norfolk to General Monk*, 1660, published in 1913.

Monk, MARIA (c. 1817-50), pretended in 1835 to have escaped from the Hôtel Dieu nunnery at Montreal, and coming to New York, found many credulous people to believe in her (lying) *Awful Disclosures*.

Monk, WILLIAM HENRY (1823-89), composer of church music, born in Brompton, was music editor of *Hymns Ancient and Modern*, and composed *Abide with Me*.

Monkey, a term best restricted to all the Primates exclusive of the Anthropoid Apes (q.v.); sometimes applied to the tailed forms only, the rest being spoken of as Apes—an ill-judged distinction, implying that the non-anthropoid Primates are divisible into tailed and tailless species. The real distinction is not to be found in this character. The quadrumana as a whole are divisible into three great groups—(1) Anthropoid Apes; (2) Platyrrhini, the New-World monkeys; (3) Catarrhini, the Old-World monkeys. It is the two latter divisions that are dealt with in the present article.

In Platyrrhini the nostrils are far apart and look outwards; tail mostly prehensile, and number of premolar teeth greater than in Catarrhini, the dental formula being (for molars and premolars) p.m. $\frac{2}{1}-\frac{3}{2}$, m. $\frac{3}{2}-\frac{3}{2}$. In the marmosets the formula is p.m. $\frac{2}{1}-\frac{3}{2}$, m. $\frac{2}{1}-\frac{2}{2}$; this, coupled with some other peculiarities in their anatomy, led to the institution of a distinct group—Arctopithecini, regarded as equivalent to either the Platyrrhini or Catarrhini. They are now, however, more usually referred to the Platyrrhini, though placed in a separate family.

a, Platyrrhine face (*Mycetes villosus*); b, Catarrhine face (*Macacus leoninus*).

In Old-World monkeys, or Catarrhini, the nostrils are near together, and look downwards; the number of teeth 32, and these arranged as in the anthropoid apes and man; the molars and premolars being p.m. $\frac{2}{1}-\frac{3}{2}$, m. $\frac{3}{2}-\frac{3}{2}$ —the reverse of the condition seen in the Marmosets. The tail, when present, is not prehensile; and there are frequently ischial callosities developed, which are entirely unknown among the American monkeys.

The two divisions of the monkey tribe based upon those characters are absolutely distinct in their geographical distribution. The Platyrrhini are only found in America, the Catarrhini are limited to the Old World; further than this, the fossil species, which have not been found in strata earlier than of the Miocene period, show the same rigid correspondence between structure and distri-

bution. No Platyrrhine has been met with in the Old World, and no Catarrhine in the New. Whether this indicates that the monkeys of the two hemispheres have had an independent origin or not, is a matter for further inquiry; it must indicate in any case the remoteness of the period during which there was a passable land connection between Asia and America.

In both the Old and New Worlds monkeys are almost confined to the more tropical districts; and yet this is not entirely due to an incapacity for bearing a rigorous climate, for monkeys occur high up on the sides of mountains in India. Monkeys do not occur in the tropical parts of Australia. During the Miocene and Pliocene periods these animals inhabited Europe and even England, for the remains of a Macaque have been described from the county of Essex. At present the only trace left in Europe of these inhabitants is the *Macacus inuus* or Barbary Ape, which occurs on the Rock of Gibraltar as well as on the opposite coast of Africa. But this animal is perhaps not truly indigenous; it may have been introduced.

In the New World monkeys are most abundant in South America. The forests of the Amazon and the Orinoco may be regarded as their headquarters. There are only ten species which occur north of the Isthmus of Panamá, and only one of these extends its range into Mexico; this is a Spider Monkey. The West Indian islands contain no indigenous monkeys. The American monkeys are all arboreal; and this of course limits their range to forest-clad districts. The prehensile tail, not found in the Marmosets, has an obvious relation to their mode of life. It is remarkable that the long-tailed monkeys of the Old World, which might often gain considerable advantage from being able to use their tail as a grasping organ, are unable to do so.

Some of the more remarkable kinds of monkeys are noticed in separate articles (BABOON, BARBARY APE, ENTELLUS, HOWLER, MARMOSET, &c.).

Monkey-bread. See BAOBAB.

Monkey-flower. See MIMULUS.

Monkey-nut. See GROUND-NUT.

Monkey-puzzle. See ARAUCARIA.

Monk-fish, another name for the Angel-fish (q.v.), was also given to a large Squid.

Monkshood. See ACONITE.

Monk's Rhubarb. See DOCK.

Monkwearmouth is now included in Sunderland (q.v.)

Monmouth, the county town of Monmouthshire, stands, girt by wooded hills, at the influx of the Monnow to the Wye, 16 miles N. of Chepstow, 18 S. of Hereford, and 26 WSW. of Gloucester. Its chief features are the ruined castle of John of Gaunt, in which Henry V. was born; the parish church, dating from the 14th century, and restored in 1882 by Street, with a graceful spire 200 feet high; the bridge over the Monnow (1272), with its 'Welsh gate,' and near it a small Norman chapel; a fragment of a Benedictine priory, with 'Geoffrey of Monmouth's study,' the town-hall (1888); and a grammar-school (1614). The Nelson Museum has a good collection of Nelson's belongings. In the neighbourhood are the temple-crowned Kymin (800 feet), commanding a glorious view; the Buckstone, a rocking-stone, displaced by tourists in 1885, but since re-poised; and, 7 miles SW., the superb ruins of Raglan Castle, defended for ten weeks in 1646 against Fairfax by the old Marquis of Worcester. First chartered by Edward VI., Monmouth united till 1918 with Newport and Usk to return a member, but is now merged in the county. Pop. 5200.

Monmouth, capital of Warren county, Illinois, is 179 miles by rail WSW. of Chicago. It is the seat of Monmouth College (United Presbyterian, 1856), and manufactures pottery, ploughs, and cigars. Pop. 8000.

Monmouth, JAMES, DUKE OF, was born at Rotterdam, 9th April 1649, the son of 'browne, beautiful, bolde, but insipid' Lucy Walter (1630-83), by Charles II., she said, but more likely by Colonel Robert Sidney, to whom and to whose brother Algernon she had lately been mistress. When in 1656 she came with her son to London, she was treated as the king's wife, and by Cromwell was sent to the Tower, and then back to Paris. Charles sought out the boy and committed him to the care of Lord Crofts, who gave him his own name. In 1662, after the Restoration, 'Mr James Crofts' came to England with the queen-dowager, and was handsomely lodged at Hampton Court and Whitehall. In 1663 he was created Duke of Monmouth, and wedded to a rich heiress, Anne, Countess of Buccleuch (1651-1732); in 1670 he succeeded Monk as captain-general of the forces, and in 1673 received the additional title of Duke of Buccleuch. A poor, weak libertine, he yet became the idol of the populace, thanks to his beauty and his affability, to his humanity towards the Covenanters at Bothwell Bridge (1679), to the agitation of the Popish Plot and the Exclusion Bill, and to his two semi-royal progresses in the west and the north of England (1680-82). There were rumours of his legitimacy, the proofs in a certain 'black box,' and Shaftesbury knew well how to pit the 'Protestant Duke' against the Popish heir-presumptive to the throne, how to enmesh him in the Rye-house Plot (1683), on whose discovery Monmouth fled, as four years before, to the Low Countries. There he remained until Charles's death, when, in concert with Argyll's Scottish expedition, with eighty-two followers he invaded England. On 11th June 1685 he landed at Lyme-Regis, and issued a manifesto branding James as a murderer and popish usurper, and asserting his own legitimacy and right to the crown. He was received with acclamations at Taunton, where he was himself proclaimed King James II.; and on the early morning of 6th July, after a roundabout march to near Bristol and Bath, he attempted with 2600 foot and 600 horse (peasants mostly and miners), to surprise the king's forces, 2700 strong, which under the Earl of Feversham were encamped on Sedgemoor, near Bridgwater. His men could not cross a broad drain, and were mowed down by the royal artillery, 300 falling on the field, 1000 more in the pursuit. Monmouth himself had fled, but on the 8th was taken, disguised as a shepherd, in a ditch near Ringwood. His bearing before James was dastardly. He wept; he crawled to his feet; he even offered to turn Catholic. No: on 15th July he was bunglingly beheaded upon Tower Hill, and buried in the chapel of St Peter-ad-Vincula. His duchess had borne him six children; but his last thoughts were all with his mistress, Lady Henrietta Wentworth, who died of sorrow nine months after him. In the 'Bloody Assize' that followed the rebellion, Judge Jeffreys hanged 331 rebels, transported 849 to the plantations, and whipped or fined 33 others.

See LIVES by G. Roberts (1844) and Allan Fea (1901), with works cited at CHARLES II. and JAMES II.

Monmouthshire, a county in the west of England, bounded NE. by Hereford, E. by Gloucester, S. by the estuary of the Severn, and W. and NW. by South Wales. With a maximum length and breadth of 32 and 28 miles, it contains 546 sq. m., of which more than one-half is under permanent pasture, and about one-twelfth in woods. Pop. (1801) 45,582; (1841) 134,368; (1881) 211,267;

(1911) 395,719; (1921) 450,700. Its surface is hilly, especially in the north and north-west (the Sugar Loaf is 1954 feet high), but the Caldicot and Wentloog Levels, which for a distance of 25 miles skirt the southern coast, are so low as to require in places the protection of sea-walls and earthworks. The Wye, with its tributary the Monnow, the Usk, Ebbw, and Rumney, all flowing south into the estuary of the Severn, are the principal rivers. In the rich valleys of the three former wheat is the principal crop raised, whilst on the poorer soils on the west side of the county oats and barley are chiefly grown. There are also extensive orchards. The great wealth, however, of Monmouthshire is derived from its minerals, coal and ironstone abounding in the region of Pontypool and Rhymney, and much fireclay, limestone, and other building stone being produced. In the county are the municipal boroughs of Monmouth, Abergavenny, and the county borough of Newport. Five members (since 1918) are returned to parliament for the county, and one for the borough of Newport; the County Council numbers 64. Towns other than the above are Abertillery, Blaenavon, Caerleon, Chepstow, Ebbw Vale, and Tredegar. Monmouthshire, which until 1535 formed part of Wales, is still for many purposes so treated. In 1921 it was detached from Llandaff and made a separate see of the Episcopal Church in Wales. Monmouthshire is noted for its beautiful scenery and for the many remains of feudal castles, &c., scattered throughout it. Of these the finest examples are the castles of Raglan, Caldicot, and Chepstow, and the abbeys of Llanthony and Tintern. See the county histories by Williams (1796), Coxé (1801), and Bradney (1904, &c.).

Monochlamydeæ. See CALYX, FLOWER.

Monochord, an apparatus constructed to exhibit the mathematical proportions of musical intervals. It consists of a flat board of 4 or 8 feet long, or better 16 feet, where space can be spared. The breadth of the board is according to the number of the strings, which are from two to six. The board is covered with fine white paper. A straight line is drawn from end to end below each string, and each line is accurately divided into the different proportions into which the full length of the string, as a fundamental sound, harmonically divides itself (see HARMONICS). The string is fixed at one end, and rests on a bridge; while at the other end, where it also rests on a bridge, it is stretched by a peg or weight. A bow is used.

Monoclinical Strata are those which are so folded as to resume their original direction, forming as it were one-half of an Anticline (q.v.), or syncline.

Monoclinic System or OBLIQUE SYSTEM, a crystallographic system in which two of the three unequal axes are oblique to each other and perpendicular to the third.

Monocotyledons are an enormous group of flowering plants usually characterised by having leaves with parallel veins and the parts of the flowers in threes; they are mostly herbaceous, trees and shrubs being less usual and almost entirely tropical. While the distribution of the woody forms is limited chiefly to the warmer zones, some of the herbaceous types abound from Arctic to Antarctic. These plants are further distinguished from Dicotyledons (q.v.) by the possession of a single evident cotyledon in the seed stage, and by the fibro-vascular bundles of the stem being more or less isolated from one another, and never forming a distinct cylinder of woody tissue. The procambial strands responsible for the formation of these bundles do not persist and form

a cambium, hence there can be no secondary growth either of wood or bark as in woody dicotyledons and gymnosperms. The stem bundles instead of forming a cylinder of wood, which in transverse section resembles a ring, appear in such a section as if scattered without order throughout the fundamental or ground tissue; in many cases, however, a cross-section reveals a helicoidal, i.e. watch-spring-like spiral, arrangement. The young stem-axis in many cases does not elongate but becomes stunted, and when this is surrounded and enclosed by modified leaf-like parts such structures as corns and bulbs are formed, as in crocus, hyacinth, lily, &c. When, on the other hand, the axis ceases to grow after producing a strong lateral bud, the elongation of whose axis is quickly arrested by the formation of another similar bud, and so on repeatedly, a false axis or sympodium results. Such a structure, generally termed a rhizome, is usually more or less subterranean, and from it the roots arise as in Solomon's seal, iris, &c. When the elongated portions of the false axis between a succession of bud origins have each the length of a few inches a kind of stolon or runner results, as in many grasses, sedges, &c. All these subterranean structures are used for storing food, for perennating the plant over an unfavourable season, or as a means of vegetative increase. These structures, as gardeners well know, are very typical of monocotyledons, and attempts at the formation of similar organs in dicotyledons may be observed in primrose, wood-sorrel, cyclamen, potato, &c., and even in ferns the same adaptation is evident, as in male-fern, &c. If a growing bulb of a daffodil and the rhizome of a male-fern are cut longitudinally and examined it will be clear that in each the axis is shortened and the old leaf bases surrounding it utilised as storage organs for food substances. The daffodil has beaten the fern on the same evolutionary line, that is all. In the case of persistent, cylindrical, woody, aerial stems, such as those of palms, the growing point from the seedling stage continues to expand the young axis in diameter until it has reached a certain maximum without simultaneously developing it to any considerable height. Several years may be occupied in this growth, during which the stem is wider above than below. This is due to the new woody bundles and fundamental tissue of each season being formed by the growing apex on the inner side of that produced in a previous season. The older, harder wood is therefore continually pushed to the outer side in contradistinction to that of dicotyledons, and with this fact in view palms were formerly said to possess endogenous stems while dicotyledons were termed exogenous. This endogenous apical mode of growth naturally limits the diameter of the trunk, so that when a young palm-stem has attained its maximum diameter it continues to elongate but does not perceptibly increase in girth. In this curious way the tall, almost uniformly cylindrical stems of many palms are produced. In the case of *Dracæna* (Parlour Palms and Dragon Trees, q.v.) the stems may reach an enormous diameter. This is due to a peripheral layer of the fundamental tissue of the stem retaining its juvenile condition, and giving origin to a sort of cambium, instead of hardening as in palms. This cambial layer gives origin to additional fundamental tissue year by year, and among it a series of separate fibro-vascular bundles, thus slowly increasing the diameter of the stem. In addition to this another exterior cambial layer is produced which forms an outer layer of cork. These monocotyledons are therefore exogens, and some of them are enormous in both size and age. The leaves are usually alternate, and seldom opposite or whorled; they

have no stipules, but in many cases possess a sheathing base, as in grasses, sedges, iris, &c. In germination the seed commonly produces a strong primary root, as in dicotyledons. This, however, soon ceases to grow, and is replaced by lateral roots, which are produced adventitiously from the base of the stem, hence the fibrous tufts of grass roots compared with the tap-root of parsnip, &c. On this account the wide-spreading root systems of such trees as oak and pine are not produced by ordinary monocotyledons; even palms have fibrous roots.
